

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

THE
GARDENERS' CHRONICLE

A Weekly Illustrated Journal

OF

HORTICULTURE AND ALLIED SUBJECTS.

(ESTABLISHED IN 1841.)

VOL. XLI.—THIRD SERIES:

JANUARY TO JUNE, 1907.

LONDON:
41, WELLINGTON STREET, COVENT GARDEN, W.C.
1907.

INDEX OF CONTENTS.

JANUARY TO JUNE, 1907.

(FOR SPECIAL HEADINGS SEE UNDER BOOKS; CERTIFICATES; LAW NOTES; NURSERY NOTES; OBITUARY; PLANT PORTRAITS; PLANTS, NEW; SCIENTIFIC COMMITTEE; SOCIETIES; AND ILLUSTRATIONS.)

A

ABBOTSBURY, Dorsetshire, damage by frost at, 174
 Abercainey, trees and shrubs at, 168
 Abies Douglasii as a forest tree, 74; A. magnifica var. xanthocarpa, 114, 159; A. nobilis and its allies, 144; A. religiosa at Trevinco, 46
 Acacia Decaisniana, 160; A. caffra flowering near Pretoria, 20
 Acacia flowers for the English market, 74, 145
 Academy, pictures at the Royal, 312
 Acantholimon echinus, a cushion plant, 311
 Adaptation of plants to their environment, 332, 372
 Adiantum Ferns in Covent Garden Market, 150
 Afforestation of waste lands, 409
 Afghanistan, gardening in, 73
 Africa, British Central, summer in, 229, 262
 Agapanthus as a hardy plant, 256
 Agaves, a disease of, 389
 Agricultural College, South-Eastern, 139, 253, 333
 Agricultural Education Committee, 205, 302, 317, 371, 388, 408
 Agricultural Exhibition at Nice, 42
 Agricultural research, donations to, 63, 190
 Agriculture at Cambridge, 40; in 1906, 26
 Alexandria, horticulture at, 286
 Algae, collection of, presented to Birmingham University, 73
 Almond, early flowering of the, 191
 Alnus incana aurea, 105
 Aloe pallida, 156
 Aloes in flower at Kew, 26
 Alpine garden at Kew, 185, 365
 Alpine garden, the, 21, 100, 198, 249, 264, 297, 379, 404, 418
 Allwood, Montagu C. (*The Perpetual-Flowering Carnation*), 370
 Alyssum Mœllendorffianum, 418
 Amateur gardeners and horticultural law, lecture on, 290
 America, Arbor Day celebrations in, 121; British gardeners in, 73, 80, 205
 American Gooseberry mildew, the, 8, 24, 29, 43, 60, 139, 238, 269
 American Irises, 418
 America, opportunities for gardeners in, 80, 191
 Anchusa italica "Opal," 387
 Andrena fulva, a burrowing bee, 320
 Anemone blanda var. scythnica, 297
 Ansellia gigantea, 362
 Apiary, the management of the, 87, 119, 155, 219, 251, 283, 298, 331
 Apple and Pear culture in Co. Cork, 19
 Apples: Ard Cairn Russet, 174; Aus Lunow, 384; Cox's Orange Pippin, 408; Encore, 3; High Canons, 133; Lord Grosvenor and Manx Codlin, 206; Minchull Crab, 94, 107; Ontario, 247; Ross Nonpareil, 182; the seedless, 59, 105; seedless, in America, 285
 Apples, some late-keeping, 223, 247
 Apple sucker, the (*Psylla Mali*), 338
 Apricot trees, caterpillars on, 60
 Aquatic weeds, to destroy, 140
 Araucaria imbricata, the fertilisation of, 209; with upright basal growths, 100, 126, 160

Arbor Day at Nebraska, U.S.A., 121
 Arboretum at Tervueren, 122
 Arboriculture in Germany, 135
 Ard Cairn, Cork, flowers at, 203
 Arpophyllum giganteum, 378
 Arundo Donax and its forms, 364
 Asparagus beds, the making of, 192
 Asparagus falcatus, 82
 Asparagus, phosphatic manures for, 41; care needed in cutting, 374; culture in the Evesham district, 329; exhibition at Evesham, 370
 Aspidistra punctata, 107
 Auricula Miss Berkeley, 286
 Australasia, emigration to, 3
 Azara microphylla, 297

B

BACTERIA in soil, 386
 Baker, J. G., awarded the Veitchian medal, 104, 188
 Bamboo, a hardy, 145
 Banana, a hardy, 101
 Bank, a dry, plants suitable for, 271
 Bank Holidays and flower show arrangements, 222
 Bassia latifolia, the Mohwa tree, 207, 223
 Bayford, C. A., presentation to, 89
 Beans, butter or wax-podded, 288; stringless and haricot, 201
 Bedding plants, the effective arrangement of, 261, 279
 Bedding, sub-tropical, 337; summer, in public parks, 337
 Beech, purple, the hardness of, 373
 Beeches, South American species of, 42
 Bees, the management of, 87, 119, 155, 219, 251, 283, 298, 331
 Begonia Gloire de Lorraine raised from seed, 29, 45, 61, 94, 141, 145, 176
 Begonia Limminghei, 247
 Belgian horticulturists, 121
 Benevolent Institution, Gardeners' Royal, 40, 72, 221, 422; annual meeting, 78
 Berberis buxifolia, 412; the garden species and varieties of, 374, 412
 Berger, Alwin (*Succulente Euphorbien*), 13
 Berlin, international horticultural exhibition at, 284; old Botanical Garden sold, 317
 Bill, Destructive Insects and Pests, 317
 Biology, economic, 11
 Bird life in London, 146
 Bird-lime, to make, 148
 Birds and buds, 288
 Birmingham, flower shows at, 284, 351; public parks, 302; University presented with a collection of Algae, 73
 Blackberries and Raspberries, 33, 60, 77
 Black Currant-bud mite, the, 221; a remedy for, 56, 145, 193
 Black-rot of Cabbages, 371
 Blair Castle, trees and shrubs at, 153
 Blancard Fund, the, 11, 25
 Blepharocalyx spiræoides, 156
 Boiler, the Cornish Trentham, 180; the Deflecta, 107; incrusting, 16

Books, Notices of:—A Concise Handbook of Garden Annual and Biennial Plants (C. M. A. Peake), 301; Alphabet of Gardening (T. W. Sanders), 410; Alpine Plants (W. A. Clark), 90; Beautiful Gardens (Walter P. Wright), 239, 269; Book of the Open Air (Edward Thomas), 222; Botanical Magazine, 25, 89, 156, 238, 370; British Plants (Dr. Rendle and J. Britten), 285; Chrysanthemums, and How to Grow Them for Exhibition (J. B. Wroe), 73; Coconut Planters' Manual (John Ferguson), 317; Critical Review of the Genus Eucalyptus (J. H. Maiden), 302; Dictionnaire Iconographique des Orchidees, 82; Die Parthenocarpie oder Jungfruchtbarkeit der Obstbäume, (Dr. Richard Ewert), 316

C. Punnett), 158; Mission Emile Laurent (E. de Wildeman), 298; Missouri Botanical Garden Report, 42; Mitteilungen der Dendrologischen Gesellschaft, 1906 (Graf v. Schwerin), 135; My Garden Diary (Sutton & Sons), 56; National Chrysanthemum Society's Year-Book (C. H. Curtis and C. H. Payne), 239; National Rose Society's Annual, 115; Nature's Own Gardens (Maud U. Clarke), 285; New Garden Plants of the Year 1906 (Kew List), 140; One and All Gardening (E. O. Greening), 56; Ootheca Wolleyana (Prof. Alfred Newton), 205; Our

Kitchen Garden (Tom Jerrold), 121; Plant Ecology (Rev. Prof. George Henslow), 220; Potato Year-Book (H. Wright and W. H. Adsett), 25, 48; Potatoes (Hon. H. A. Stanhope), 205; Progressus Rei Botanicae (Dr. Lohs), 57; Publications Received, 11, 58, 74, 105, 122, 141, 191, 239, 303, 318, 388, 423; Quarterly Journal of Forestry (Prof. Fisher), 57, 301; Rambles on the Riviera (Dr. Strasburger), 69; Recent Progress in the Study of Variation, Heredity, and Evolution (R. H. Lock), 53; Revue Horticole, 25; Royal Horticultural Society's Report on the Conference on Genetics (Rev. W. Wilks, M.A.), 252; Seaside Planting of Trees and Shrubs (A. Gault), 328; Seasonal Botany (Mrs. M. O'Brien Harris), 58; Studio Year-Book of Decorative Art, 253; Succulente Euphorbien (Alwin Berger), 13; Sweet Pea Annual, 42; Text Book of Plant Diseases (George Massee), 222; The Book of the Open Air, 285; The Book of Vegetables (Allan French), 342; The Dillenian Herbaria (Claridge Druce), 284; The Flowers and Trees of Palestine (Augusta A. Temple), 285; The Modern Carnation (Hayward Mathias and P. Smith), 136; The Perpetual Flowering Carnation (Montagu C. Allwood), 370; The Principles of Horticulture (Wilfred Mark Webb), 247; The Unheated Greenhouse (Mrs. K. L. Davidson), 366; Trading Made Easy (Charles A. Howfe), 140; Transactions of the Royal Scottish Arboricultural Society, 26
 Boring pests of fruit trees, 318
 Botanical nomenclature, international rules of, 17
 Botany, economic, at Manchester, 105
 Bothy accommodation for young gardeners, 122
 Bramble hybrids, 60
 Brandis, Sir Dietrich (*Indian Trees*), 231
 Brandegee herbarium presented to California University, 10
 Brasso-Lælio-Cattleya Fowleri, 303
 Brazilian Orchids, 191
 Bribe to gardeners, offered by foreign nursery firm, 73
 British Central Africa, summer in, 229, 262
 British gardeners in the United States, 73, 80, 205
 British Guiana, exports of rice from, 410
 Britten, J., and Dr. Rendle (*British Plants*), 285
 Broccoli, spring, 241
 Brown-rot of fruit, 379
 Brussels Botanic Garden, fern-house in, 312
 Bryophyllum calycinum, 422
 Buds destroyed by birds, 288
 Bulb-mite, to destroy, 77
 Bulbs, Guernsey, 57
 Bulgaria, the vegetable products of, 388
 Bunyard, Geo. (*Fruit-Farming for Profit*), 90
 Burbank, Luther, 141
 Burdett-Coutts, the late Baroness, 173
 Burn, John, Mr., 238
 Business, how to start a nursery, 243

C

- CABBAGES and Cauliflowers, black-rot disease of, 371
 Cabbage, red, the hardness of, 373
 Cabbages, autumn and winter, 13;
 bolting and non-bolting, 327
 Caiophora coronata, 156
 Calabash used for making pipes, 134
 Caladiums, variegated, raising, 125
 Calanthes, deciduous, the culture of, 90
 Calceolarias, a monograph of the species of, 254
 Calcutta Botanic Garden, 25
 California, herbarium presented to, 10; the Onion seed crop in, 388
 Callas (*Richardia africana*) planted in an open lake at Byram Park, 320
 Callispyche mirabilis, 101
 Caltha palustris "polypetala," 256
 Cambridge University farm, 40
 Camellia, a large, in Leonard'slee Gardens, 208; the hardness of the, 193, 374, 389
 Camellias out-of-doors, the culture of, 297
 Campanula garganica hirsuta alba, 404
 Canada, fruit prospects in, 387
 Canker, Rose, 313
 Canterbury, a pinetum at, 305
 Cape Colony, fruit culture in, 230
 Carbolineum, a spray for fruit trees, 14
 Carbon supply of plants, a puzzle, 277, 304, 374
 Cardiff City gardeners, 173
 Carnation flowers, a sheath for, 73
 Carnation-house, best kind of, 125
 Carnation pest (*Alternaria* sp.), 371
 Carnations, American winter-flowering, 190; at Porter's Park, 174; at Swan Lane Nurseries, 38; fraudulent sale of, 211, 241, 256; in America, 139; manure for, 396; select varieties for winter-flowering, 93; suitable structure for, 96; winter-flowering, a French note on, 301
 Carrots, winter and spring, 66
 Carson, D., presentation to, 203
 Cassia auriculata, a Tea plant, 334
 Castle Kennedy, trees and shrubs at, 192
 Catalpa cordifolia, 217
 Cat as a scarecrow, 160, 189, 211
 Caterpillars on Apricot trees, 60
 Cats in the garden, 160, 211
 Cattleya fly, the 94
 Cattleyas, white, the breeding of, 21
 Cauliflower and Cabbage rot disease, 371
 Cauliflowers, early varieties of, 247
 Ceanothus thyrsiflorus at Kew Gardens, 221
 Cedar at Childrick, 223
 Cedars at Kew, the, 25
 Cedrus Deodara around London, 128
 Celeriac as a winter vegetable, 37
 Cereus grandiflorus, 412
 Ceropegias in cultivation, species of, 20
- CERTIFICATED FRUITS AND VEGETABLES.**—Kale Chou de Russie, 195; Melon Eminence, 427; Orange Excelsior, 109; Pear Bickling, 31; Strawberry Kentish Favourite, 427
- CERTIFICATED PLANTS.**—Acineta Humboldtii, 290; Actinidia chinensis, 358; Agapetes speciosa, 258; Amphieme Emodi, 426; Auriculas: Brightness, 258; Miss Berkeley, 258; "Henry Marshall," 322; Azalea Mme. Anthony Koster, 358; Begonias: Lady Cromer, 358; Mrs. J. C. Gwillim, 358; Rhoda Pope, 358; Wm. Marshall, 358; Brasso-Cattleya Digbyano-Schröderæ "Fowler's variety," 290; B.-C. H. G. Alexander, 161; B.-C. Pluto, 31; Brasso-Catt.-Lælia x Veitchii, 259; Brasso-Lælia Gipsy, 290; Brasso-Lælia-Cattleya "Fowler," 290; B.-L.-C. Lido, 354; Caladium Thomas Tomlinson, 358; Calceolaria Veitch's Hybrid, 426; Carnations: Jessica, 289; Marmion, 358; The Squire, 426; Cattleya Maggie Raphael alba, 31; C. Mendeli Francis Wellesley, 393; C. Mossiæ Princess of Wales, 354; C. Trianæ Mooreana, 226; C. T. The Premier, 161; Cirrhopetalum gracillimum, 427; Clivia miniata var. citrina, 322; Celogyne asperata, 427; C. Colmanii x, 109; Coleus Cordelia, 426; Cymbidium Colmanæ, "Edensie variety," 195; Cymbidium insignis, "Glebeland's variety," 161; Cypripedium Dicksonianum, 161; C. "Mrs. Francis Wellesley," 161; C. Tautzianum nigricans, 62; C. tibeticum, 353; C. vill.-exul., 161; Cyrtomium falcatum Rochfordii, 160; Cytisus Firefly, 358; Davallia braziliensis, 392; Dendrobium chryseum giganteum, 290; Dendrobium Wilsonii, 290; Erym gracile, 426; Freesia Chapmanii, 160; F. Tubergenii Amethyst, 258; Gladiolus atro-violaceus, 322; Haberlea rhodopensis var. virginialis, 322; Hartwegia purpurea, 427; Hippeastrum Lady Howick, 225; H. Mrs. Carl Jay, 392; H. Vulcan, 225; Hydrangea arborescens var. grandiflora, 322; Irises: Aspasia, 160; x Caterina, 392; King of the Whites, 426; x Luna, 322; l'Unique, 426; Melusine, 160; Mrs. W. T. Ware, 426; paracina, 392; Kalanchoe Dyeri, 108; Lachenalia May Crosbie, 160; Lælia anceps Schröderæ "Grace Ruby," 62; Lælia-Cattleya Baroness Schröder, Westonbirt variety, 226; L.-C. Frederick Boyle var. Kerchoveæ, 290; L.-C. Ganymede, 290; L.-C. Golden Glory, 353; L.-C. Lawrie, 226; Lissochilus giganteus, 427; Lonicea Maackii, 392; Lycaste Balliæ, South Lodge variety, 161; Magnolia Soulangeana nigra, 194; Maxillaria grandiflora, 62; Meconopsis racemosa, 392; Miltonia vexillaria chelsiensis superba, 393; M. v., Westonbirt variety, 353; Narcissi: Ailsa, 289; Aphrodite, 273; Homespun, 225; Brillancy, 273; Corallina, 273; Glitter, 273; Kestrel, 273; Miss Willmott, 289; Nephrolepis exaltata var. Whitmanii, 108; Odontodia Bradshawæ, 30; Odontoglossum "Aliceæ," 31; O. ardentissimum "Herbert Goodson," 259; O. a. Robsonæ, 353; O. caloglossum, 62; O. cœruleum, 354; O. crispum album, "Orchid Villa" variety, 226; O. c. Rosemary, 195; O. c. Lily Bourdas, 195; O. c. Mossiæ, 161; O. c. Solum, 353; O. c. xanthotes, 353; O. c. x. "White Lady," 323; O. eximium "King of England," 353; O. gandavense, 353; O. Lady Howick, 195; O. Lambeauianum "Ideal," 109; O. Thompsonianum superbum, 354; O. mirum "Lady Howick," 161; O. "Othello," 259; O. Prince Edward of Wales, 290; O. Roi d'Angleterre, 226; O. Ruby, 62; O. venustum "Apollo," 109; Oncidium leuochilum "Mr. F. J. Hanbury," 323; Papaver Princess Ena, 353; Jennie Mawson, 426; Phæo-Calanthe Colmanii, 31; Plocoglottis Lowii, 427; Primula Cockburniana, 258; P. stellata (strain), 160; P. x Unique, 358; Pyrus (Cydonia) japonica Simonii, 289; Rhododendron amœnum Here, 160; R. Duke of Cornwall, 194; R. intricatum (nigro-punctatum), 226; R. Kewense x, 194; Roses: Dr. William Gordon, 358; Pharisæer, 258; Richmond, 161; Saxifraga aizoon rosea, 358; S. Burseriana Gloria, 194; Sophro-Lælia-Phroso superba, 259; Spathoglottis Colmanii aureum, 161; Sweet Peas Carmine Paradise, 427; Evelyn Hemus, 427; Syringa Josikæa eximia, 392; Tulips: Gorgeous, 358; Le Grandeur, 289; Verbena Aubletia compacta, 358
- Ceylon Botanic Garden, 215
 Ceylon, rubber culture in, 11
 Chamærops Fortunei, 254; C. humilis, a European Palm, 213
 Chenopodium Bonus-Henricus as a vegetable, 287
 Cherry, Early Rivers, 67
 Chicago University, gifts to, 105
 Childrick, an old Cedar at, 223
 China, a letter from, 422
 Chionocilla "The Queen," 249
 Chittenden, F. J., 56, 233
 Chlorophyll, the action of, in relation to light and temperature, 254

NOVEMBER AND DECEMBER IN MY FLORIDA GARDEN.

FLORIDA is a country rarely visited by frost, and is always a glorious land.

The sun god finds so much of beauty here that he kisses all the land with his tenderest, softest touch; and the rains come but caress. Though the golden orange gleams the dark foliage, it is not the land of the hidden dollar, for riches are not accumulated here, as in some other parts of this land of unlimited possibilities," but Florida offers simply an ideal life in an ideal climate. The autumn months are, in Florida, the season when plant-life has reached its latest development and perfection. The winter period is then over, and the air becomes clearer, drier, and more invigorating. The mocking bird, who paused for months, sings again, but its melodies are now far sweeter, purer, softer, and more sustained than in early spring-time, when it simply bursts out in loud and joyous exultation. In the north, winter-time is the season of inspiration, hope, and promise—the season of flowers and birding, while autumn is the time of the serene yellow leaf. William Cullen Bryant characterises November in the following verse:—

The melancholy days have come, the saddest of the year,
wailing winds and naked woods, and
meadows brown and sere."

How different is all this in Florida, where, in November, the days are bright and sunny, cheerful and inspiring. The woodland floor is still covered with a carpet of bright and brilliant blossoms. The woods, where Magnolias and wild Olives (*Osmanthus americana*) live, and in which Oaks and Cabbage palmetto (Palms) predominate, show a deep, glossy green hue, which is so intensely bright in this glorious sunshine that the rays of light are constantly reflected, and sparkle in endless flashes, as if innumerable small mirrors were suspended among the foliage. This is a very characteristic feature of woodlands in which *Magnolia grandiflora*, the undisputed queen of this southland among forest trees, reigns supreme.

Here the sun shines in November as bright as ever, but his power is moderated by cool breezes, and the brilliant moonlit nights give a feeling of inexpressible enchantment. The air, even in midsummer, becomes delightfully cool and invigorating after sunset, and fragrant with the odours of fruits and flowers. In the autumn months the extreme transparency of the atmosphere gives not only all parts of the landscape an astonishing clearness of outline, but even the sky does not look so high, nor so far away, as in the north, and at night-time the stars appear larger, their luminosity is greater, and they seem to be nearer, sparkling with wonderful glory and brilliancy. The air in "fall" and winter is particularly clear, and human voices can be heard at a great distance. Dews are very heavy during the nights, and all plants are dripping with moisture when the sun rises. Such a sunrise is very clear and grand, though the sunset is still more sublime and impressive, because of its wonderful, glowing lines. The whole sky in the west appears to be in flame, and this glorious sight lasts until night falls.

My garden swarms with northern song-birds from October to April, and even later, but only now and then can snatch of their song be heard. The noisy blue-jay, however, is an exception, and its screaming notes are almost always noticeable. Butterflies, moths, wasps, and particularly bees, crowd among the flowers, of which the garden now shows a greater wealth than at any other time of the year. The huge flower-spikes of *Cocos Blumenavia*, *C. Yatay*, *C. Gaertneri*, *C. Bonneti*, which almost daily burst their heavy club-like spathes with a peculiar noise, are swarming with such a number of bees that their humming can be heard at quite a distance. Fruit of the genus *Citrus* is seen in abundance, the golden Orange, the Lemon and Lime, the massive Pomelo and Shaddock, the brilliant Tangierine and Mandarin, and the liliputian Kumquat are all gleaming in the beautiful, dense, dark green foliage of the trees. The Florida Orange is highly prized, being juicy, heavy, sweet, and aromatic. Many of the large guava bushes are still covered with their strangely odoriferous, delicious fruits, and Pine Apples ripen in quantity. The fragrance of many of the flowers, particularly *Elæagnus reflexa* and *E. Simoni*, is very sweet; while the delicious perfume of the Angel's Trumpet (*Datura suaveolens*), of the night-blooming Jasmine (*Cestrum nocturnum* and *Cestrum Parqui*), and of *Criminum amabile*, *C. augustum*, *C. asiaticum*, and *C. giganteum*, is almost overpowering. The perfume of the Roses, especially of the most glorious and queenly of

them all, the far-famed Marechal Niel, of the woodland Margaret, Lamarque, Gloire de Dijon, Cloth of Gold, Reine Marie Henriette, Kaiserin Augusta Victoria, and many Tea Roses, pervades the atmosphere around my house with fragrance. At this time of the year many of the most desirable and showy ornamental trees and shrubs present a display of blossom and foliage unexcelled at any other season of the year.

TECOMAS, &c.

Among the beauties of my garden throughout the month of November, the Yellow Elder (*Tecoma stans*) is undisputed queen. Bushes of this plant around the dwelling house have attained to a height of from 15 feet to 18 feet and are about the same in diameter. How indescribably grand are the large panicles of their flowers that terminate the shoots! The branches are literally laden down with great trusses of brilliant yellow, delicately scented, large funnel-shaped blossoms. Humming-birds are constantly engaged in their work of capturing minute insects among them, and bumble-bees, butterflies, and a host of other insects swarm around and in the flowers. The colour harmonises beautifully with the light green of the abundant foliage. *Tecoma mollis* (*T. velutina*) and a few other varieties are also in bloom, but they are much less showy, being far surpassed by their beautiful and gigantic congener.

The Cape Honeysuckle (*Tecoma capensis*), which is scarcely ever out of bloom, is now at its best condition. The brilliant, orange-scarlet flower trusses, which are very effective, as spread over the very dark green foliage, have the appearance of flames. It is a half-twining shrub and a very common and pretty object in the gardens of Florida.

Near these two shrubs a *Lasiandra* (*Tibouchina semidecandra*) displays its unique brilliancy, its satiny purple-blue flowers, as large as a silver dollar, contrasting wonderfully with the bright yellow of *Tecoma stans* and the orange-scarlet of the Cape Honeysuckle. This Brazilian shrub attains to a height of 6 to 8 feet, and even more. The abundant, strangely-nerved foliage is of a dark green colour above and silvery-white beneath, and of a velvety texture, caused by the dense covering of soft short hairs. Many of the older leaves assume a bright yellow and orange-scarlet hue, which enhances the beauty of the plant considerably. It flowers from June until late in winter, and is able to withstand much more cold than the Yellow Elder.

A big clump of *Jacobinia coccinea* occupies a favoured spot close by the house. It is about 7 feet high and over 5 feet in diameter, and is surmounted by hundreds of bright scarlet blossoms on crimson stems, the whole inflorescences being arranged in large, open, pyramidal panicles. Each shoot is terminated by a very conspicuous flower spike. The foliage is large, dark green in colour, decidedly tropical in appearance, and is abundantly produced. This plant always forms a prominent object in the garden, and planted in large beds is much more effective and ornamental than the scarlet Sage, though not quite as resplendent. It blooms all through the summer months in profusion, but now is the season of its greatest glory and its fullest development. The first slight frost will cut it to the ground, but in spring it sprouts again vigorously from the rootstock. It is one of our choicest flowering plants, and it forms

one of the most characteristic features of our gardens.

Smaller and less conspicuous is the large-flowering Cigar plant (*Cuphea micropetala*). This species usually grows 3 feet in height, and is often 5 or 6 feet in diameter on account of the branches forming roots wherever they touch the ground. The rather large flowers are arranged in terminal spikes; they are of a yellow colour, flanked with brownish-crimson. The

The so-called Bluebird Flower (*Dædalacanthus nervosus*) is a fine companion plant to the Jacobinia. Its growth is dense and very ornamental; its flowers, which are produced in great abundance, are of a beautiful sky-blue colour.

LANTANAS.

Just now, too, the Lantanas are at their best. A fine clear, bright yellow variety of *Lantana Camara* grows wild around here along fences

particularly value a rather dwarf kind, which develops bright yellow-coloured flowers that change to a vivid orange and finally to a deep maroon tint, and another more upright and strong-growing kind, with flowers of a pure primrose-yellow, changing to pink and finally to a deep violet. There are many other varieties of Lantanas, but most of them are too vigorous in growth, and encroach upon their surroundings. I have seen plants with a spread of from

FIG. 1.—NEW SEEDLING APPLE "ENCORE": SKIN PALE YELLOW OR GREENISH, WITH RED STREAKS TOWARDS THE BASE OF THE FRUITS.

(For text see page 3.)

Madagascar Periwinkle (*Vinca rosea*), a pure-white flower with a red eye, is also now in full bloom. This plant finds the soil and the climate of this country so congenial to its requirements that it frequently escapes from the gardens and grows luxuriantly on the roadside. The same may be said of *Clerodendron fragrans* and the tall *C. Siphonanthus*, the first-named being in full bloom late in the "fall," while the second is conspicuous on account of its clusters of bluish-black fruits.

and on the edges of thickets. In full bloom it is a very conspicuous object, and a valuable acquisition for the garden. Another species, more delicate and straggling in growth and with small heads of slightly fragrant flowers of rosy-lilac colour, is frequently found along roadsides and in old neglected gardens and back yards. This is *Lantana Sellowiana*, a fine trailing plant when well grown. The range and the change of colour among these plants is quite surprising under this congenial sun. I

25 to 30 feet and 10 feet in height. They do not appear to smother other more delicate and shade-loving subjects; in fact, I have repeatedly found other plants, including *Hippeastrums*, *Hymenocallis*, *Ismenes*, and *Camellias* vigorously growing by their side, or even underneath them. The falling leaves of the Lantanas enrich the soil wonderfully, and this undoubtedly is the cause of the luxuriant growth of all plants growing near them.

(To be continued.)

NEW OR NOTEWORTHY PLANTS.

CLEMATIS QUINQUEFOLIOLATA.*

ABOUT eighty species of *Clematis* have now been described from China. The above plant was sent to Kew for identification by Messrs. Veitch and Sons, and was raised from seed collected by Mr. E. H. Wilson in the mountains to the north of Kwei. It is closely allied to *C. leyeniana* Walp., but differs in having five leaflets instead of three, and less numerous flowers. The flowers are milky-white in colour, and are borne, five or six together, on axillary peduncles, which are slightly shorter than the leaves. This species has been confused with *C. recta*, L., by Finet et Gagnepain in *Flore de l'Asie Orientale*, who quote Wilson, No. 1,442, under that species. It is a totally different plant from the typical *C. recta*, having fewer flowers and leaflets, which are quite distinct in shape. It appears to be a robust, free-flowering plant, which will probably prove a useful addition to the already large collection of hardy *Clematis*.
Hutchinson, Kew.

COLONIAL CORRESPONDENCE.

EMIGRATION TO AUSTRALASIA.

As one who has followed farming and horticultural pursuits all my life in Australian States, I feel constrained to offer some advice to readers of the *Gardeners' Chronicle* who contemplate coming out to these states, or of sending their sons, to take up farming, pastoral or horticultural pursuits. There is room and place for thousands of comers if they are energetic, persevering and steady, but throughout our different States (with the exception of Queensland, where I have not been), I have seen so many sad fates where capital and labour have been wasted through lack of knowledge, or through neglecting to obtain reliable advice when starting out to the best districts in which to settle each of our Colonies for different pursuits, in agriculture, sheep farming, dairying, stock, fruit-growing. Conditions here are so different to those of the Old Country, that newcomers have a great deal to learn. Not only a knowledge of the best localities requisite, but some additional knowledge as to different uses of soil is required, as in the best possible districts for, say, dairying, there are farms which are almost worthless for such purpose—these are usually the ones that are for sale. It must be remembered that Australia is a continent, reaching from comparative proximity to the South Pole circle right up to influence of the Equator in the northern part of Queensland, and there are variations of soil and condition from that of Tasmania (which approaches closely that of the south of England) in various grades up to tropical climate. Each portion is especially suitable for certain trees, and the annual rainfalls in the several States are measured from a very few inches to several feet.

CLEMATIS QUINQUEFOLIOLATA, *Hutchinson sp. nov.* scandens; caulis lignosus, canaliculatus, pubescens, nunc fere glaber. Folia pinnatifida quinquefoliolata; es circa 15 cm. longi; foliola petiolulata, oblongo-lanceolata, usque ad 9 cm. longa et 3 cm. lata, obtusata vel subcordata, apice mucronulata, incrassata, costa pubescente excepta, glabra, subtus glabra, venis raris tribus supra leviter impressis, subtus prominulis; ulus circa 4 cm. longus. Cymæ axillares, paucifloræ, folia paullo breviores; pedunculi 3-5 cm. longi; caliculi interdum foliacei; pedicelli 3-5 cm. longi; corolla 4 vel 5, oblonga, intus alba, glabra, extus præcæpue argentea, cinereo-villosa; filamenta glabra, complanata, longa; antheræ 2 mm. longæ. Achenia immatura a. West Hupeh, Wilson, 718, 1,442, 1,608, 2,810; g. Henry, 4,185, 808 (?). Nanto and mountains to north of Henry.

The vastness of the land; from the corners of which one might cut out an England, Ireland, and Scotland and hardly miss them, must be borne in mind by intending settlers; also the varied conditions of climate, &c., existing therein. The average newcomer on reaching here lands at Adelaide, Melbourne, or Sydney. If he has capital he is anxious to purchase a farm, sheep-run, or orchard at once, and casts about for such places that are offered him through agents. After purchasing, much above local values, he probably finds, after spending all his capital, and years of his life in hard toil, that he has been saddled with a property utterly unsuited for the successful production of the crops he has taken it up for. The property is mortgaged, usually lost, and lacking sufficient means to start elsewhere he drifts away to make a living as an unskilled workman. All such failures would be avoided if the newcomer had obtained some proper advice before starting. All intending comers should be able to state definitely when seeking such advice (1) Their age, and if capable of hard work; (2) the amount of their capital; (3) whether they have had any practical training on land, and what pursuit they desire to follow be it sheep-grazing, cattle-breeding, agriculture or fruit-growing. *H. McEwen, manager, Tasmanian Nurseries, Launceston, Tasmania.*

FORESTRY.

"WOODS FOR EVERYBODY."*

THE principal value of this article is in the recommendation to plant small odd corners of our fields with suitable forest trees. But evidently the fact has been lost sight of that although large areas of planting may be carried out at a five-pound note per acre, nearly double that amount is required to fence, pit and plant a single acre on the farm or small private holding. As large plantations are usually formed on exposed and comparatively worthless land, the plants used must necessarily be of small size, but by the dwelling-house or on the farm plot, where the soil is invariably of good quality and the situation sheltered, for obvious reasons much larger trees are, and should be, planted. The cost of trees is given quite correctly, but there is nothing opposite pitting or planting. According to the writer, 2,722 trees should be planted to the acre; therefore, instead of £5 the following amount will be much nearer the truth:—

Opening 2,722 pits at 2s. 6d. per	
100	£3 8 0
2,722 trees at 40s. per 1,000	5 8 0
Planting	2 0 0
	£10 16 0

It will be seen that nothing is put opposite fencing or otherwise protecting the young trees. It should be distinctly remembered that I do not say that planting cannot be carried out at a lower figure than £10 per acre, especially when considerable areas are to be dealt with, but with small plots around dwelling-houses, where immediate effect is often a point of first consideration, the five-pound note will by no means cover the outlay.

It is wrong to recommend the Scotch Fir for damp ground—dry, gravelly pan being its medium, and excellent results have often followed the "notching" of young trees up to 6 or 8 inches in height. The good effects of exposing soil to the weather are too well known to be easily refuted, while the exposure of the ground has everything to do with the size of trees that should be planted.

Some excellent advice is given as to the choice of trees and planting, and this with the

* "Woods for Everybody!" How several residents may have an acre of forest trees for a five-pound note, being an article which appeared in the *World's Work*.

commendable idea of utilising waste corners for the growth of trees, will make the article of considerable value to the amateur planter.

FORESTERS' POCKET DIARY.

THIS is a very handy little book for the use of foresters, agents, nurserymen, &c., published by William Rider and Son, and compiled by Mr. A. D. Webster. The first article is devoted to the afforesting of waste land. Mr. Webster computes that there are in the British Isles about nine millions of acres of land, the rental of which is worth, on the average, not more than three shillings an acre, but which could advantageously be afforested. Mr. Webster urges that the State should gradually become possessors of this land for forestry purposes at a purchase rate of, say, 40s. per acre. He has little faith in the efficiency of private enterprise. If one million acres were planted during 25 years at the rate of 40,000 acres a year, and at a cost of £290,000 a year, great permanent benefit would be ensured. The expenditure of £290,000 is not much in comparison with the £25,000,000 annually expended by this country on supplies brought from abroad. Mr. Webster calls attention to the planting of Larch on the peat bogs of Ireland, where it appears the canker caused by the *Peziza* is almost unknown. Various matters of interest to foresters are given in this little book. Amongst other things we find a notice of the great Dragon tree of Teneriffe, but this was destroyed by a gale some years since, and, as we believe, the only authentic illustration of the tree from a photograph was given in our columns (June 8, 1872, p. 765). The names of the fungi at pp. 31, 32 need revision; indeed, the names of plants generally are often peculiar. The address of the Royal Horticultural Society is no longer at 117, Victoria Street. Mr. Walter Wright is no longer the secretary of the National Potato Society.

As showing the necessity for uniformity and regular proportion in our weights and measures, we note that Mr. Webster enumerates sixteen different measurements of acres in various countries, whilst in lineal measure, as every school-boy knows, the numbers run in irregular sequence from 12, 3, 2, 5½, 4, 10, 40, 8, 3, 69½ to 360. In square measure and cubic measure the want of proportion is equally apparent, and yet we pride ourselves on being a practical people and talk about an ounce of practice being of more importance than a ton of theory. Where the common sense comes in we fail to see. In spite of the few misprints we have had occasion to notice, Mr. Webster's forestry diary is most useful. No one wanting to give a serviceable present to a forester or land agent could do better than select this little pocket-book.

APPLE "ENCORE."

THE fruits shown in the illustration at fig. 1 represent a new culinary Apple raised by Mr. C. Ross, gardener at Welford Park, Newbury, from a cross effected between the varieties Northern Greening and Warner's King. At the R.H.S. meeting, held on December 11, the Fruit and Vegetable Committee unanimously recommended an Award of Merit to the seedling, and from the appearance of the fruits then exhibited they would be likely to last in good condition until March, being thus an excellent late-keeping variety. A description of the fruit was printed in our issue for December 15, p. 414, and the present illustration, which has been prepared from a drawing by Mr. Worthington Smith, being of life-size, needs no further explanation. The value of this Apple will depend, as it does in the case of most other fruits, upon its habit of growth, free cropping qualities and suitability for cultivation in a particular locality. We do not know whether the tree flowers early or late in spring, but, in view of the annual losses caused by late frosts, this is a most important matter to cultivators.

PLANT-NOVELTIES IN 1906.

ORCHIDS.

TURNING to the Awards of the Committees of the Royal Horticultural Society, which gives the best record of sterling novelties of the year, we find that all branches of horticulture have been well supplied with new plants during the past year, the number of new Orchids having been exceptionally good. In this branch the hybridists still maintain the lead, although there are signs that the introduction of good and new species by means of importation, and of albinos and fine varieties of species, is still largely sought by collectors.

Among fine species shown during the past year, specially remarkable were the noble specimens of *Lissochilus Horsfallii*, imported by the Hon. WALTER ROTHSCHILD (gr. Mr. A. Dye), and for a group of which the Royal Horticultural Society's Silver-Gilt Flora Medal and First-Class Certificate were awarded on March 6.

Major G. L. HOLFORD, C.I.E., C.V.O., Westonbirt, Tetbury (gr. Mr. H. G. Alexander), takes a leading place as the raiser and exhibitor of some of the best novelties of the year, his awards having amounted to about a score, half of which secured First-Class Certificates, and the rest Awards of Merit. The former included *Cypripedium Alcibiades magnificum*, *C. Actæus langleysii* (see fig. 10), *Cymbidium Lowio-grandiflorum*, *Cattleya Whitei splendidissima*, C. Lord Rothschild, Westonbirt variety, C. Duseldorffii Undine, C. Iris Countess of Morley, C. Cleopatra and *Sobralia Holfordii*; while the Award of Merit varieties were *Brasso-Cattleya Madame Jules Hye*, *Cattleya Ashtonii*, Westonbirt variety, *C. fulvescens delicata*, C. Trianae, Westonbirt variety, *Lælio-Cattleya Baroness Schröder delicata*, L.-C. Sunset, L.-C. Berthe Fournier, Holford's variety, *Cypripedium nitens*, Ball's variety, *Cymbidium Wiganianum*, Westonbirt variety, *Sophræ-Lælia Phroso* and *Sobralia Amesiae*, all good things and presented in the highest condition of good culture.

Sir TREVOR LAWRENCE, Bart., Burford (gr. Mr. W. H. White), while appreciating good hybrids, still retains his liking for pretty and curious species for which his long list of awards has mainly been secured. He is credited with *Catasetum splendens punctatissimum*, *Cynoches Egertonianum viride*, *Mormodes Buccinator theiochlorum*, *Epidendrum floribundum*, *E. confusum*, *E. odoratissimum*, *Dendrobium Wiganiae illustre*, *D. lasioglossum*, *Chysis Sedeni*, *Masdevallia igneo-Estradæ*, *M. ignea*, Burford variety, *Thunia Veitchiana*, Burford variety, *T. Marshalliana alba*, *Maxillaria molitor*, *Houlletia odoratissima xanthina*, *Stelis muscifera*, *Cirrhopetalum Amesianum*, *Quekettia Jenmanii*, *Polystachya grandiflora* and *Lælio-Cattleya Myra*, Burford variety.

FRANCIS WELLESLEY, Esq., Westfield, Woking (gr. Mr. Hopkins), who in *Cypripedium Thalia* Mrs. Francis Wellesley, produced one of the finest *Cypripediums* of 1905, this year repeats the honour with *C. Germaine Opox*, "Westfield variety," which, like the other hybrid mentioned, in addition to securing a First-Class Certificate, also obtained a First Diploma. In *Brasso-Cattleya* "Mrs. Francis Wellesley," which obtained a First-Class Certificate on April 17, we have the largest and best *Brasso-Cattleya*, and other fine novelties shown by Mr. WELLESLEY were *Cypripedium "Bella"*, Westfield variety, *C. Boxallii nigricans*, C. villosum "The Premier," *Cattleya intermedia White Queen*, C. Mendelii Mrs. Frederick Knollys, *Brasso-Lælia Mrs. M. Gatrix*, "Westfield variety," *Lælio-Cattleya Hopkinsii*, L.-C. Mrs. de Vere Beauclerk, and L.-C. Helena, Westfield variety.

Sir FREDERICK WIGAN, Bart., Clare Lawn, East Sheen (gr. Mr. W. H. Young), secured First-Class Certificates for *Bulbophyllum virescens*, one of the most beautiful new species of the year; *Cymbidium I'Ansoni*, *Cypripedium Muriel Hollington*, *Cattleya Fabia superba*, and

other awards for *Oncidium monachicum*, *Lælio-Cattleya Kathleen Grey* and *Hemipilia amethystina*.

J. GURNEY FOWLER, Esq., Glebelands, South Woodford (gr. Mr. J. Davis), received First-Class Certificates for *Cypripedium callo-Rothschildianum*, a fine specimen of which he showed at the Holland House exhibition; for *Ærides Houlletianum*, Fowler's variety, one of the largest and best *Ærides*; and the graceful and pretty *Cymbidium erythrostylum*, one of the fortunate importations from Annam, made by Messrs. Sander & Son; also Awards of Merit for *Cypripedium Miss Louisa Fowler*, superbum, *Cattleya Mantinii*, Fowler's variety, C. Atalanta, Fowler's variety, *Lælio-Cattleya Woodfordiensis*, and *Odontoglossum amabile*, Glebelands variety.

JEREMIAH COLMAN, Esq., Gatton Park, Reigate (gr. Mr. W. P. Bound), from the magnificent group which he staged at the Royal Horticultural Society in the spring secured Awards of Merit for *Dendrobium Brodiei*, D. Othello Colossus and D. Wiganianum, Gatton Park variety, and at the Temple Show for *Masdevallia Harryana*, Gatton Park variety, and *Cattleya Mossiae Jeremiah Colman*; and at other times similar awards for *Spathoglottis Colmanii* x, *Cymbidium Colmanæ* x, *Lælio-Cattleya Phyrne*, Gatton Park variety, all raised at Gatton Park; and *Dendrobium Phalaenopsis*, Gatton Park variety, a pretty white form with slate-blue tint and veining on the lip.

Baron Sir H. SCHRÖDER, The Dell, Egham (gr. Mr. H. Ballantine), from his fine collection secured First-Class Certificates for the large and handsome *Lælio-Cattleya callistoglossa*, The Dell variety, and the fine *Cattleya Mossiae Reineckiana* "The Baron"; also a Botanical Certificate for the pretty *Cynorchis compacta*.

J. BRADSHAW, Esq., The Grange, Southgate (gr. Mr. G. G. Whitelegge), received a First-Class Certificate for *Cymbidium erythrostylum*, and Awards of Merit for *Brasso-Cattleya Digbyano-Mendelii* "Fortuna," *Lycaste tricolor*, *Lælio-Cattleya G. G. Whitelegge*, a fine and richly-coloured flower; also *Cattleya Fabia Bradshawiae*.

H. S. GOODSON, Esq., Fairlawn, West Hill, Putney (gr. Mr. G. E. Day), from his important collection received First-Class Certificates for *Cattleya Fabia Goodsonii* and C. Octave Doin var. Herbert Goodson, two of the most gorgeous *Cattleyas* of the year, the latter also securing a First Diploma.

Other good novelties shown by amateurs included the fine *Cattleya Mrs. J. W. Whiteley* and *Odontoglossum crispum-Harryanum*, both distinguished as Rosslyn variety, and for which H. T. PITT, Esq., (gr. Mr. Thurgood) received First-Class Certificates; *Lycaste Skinneri Fascinator* and *Cypripedium aureum Hyeanum* from F. MENTEITH OGILVIE, Esq. (gr. Mr. Balmforth); the unspotted *Odontoglossum Rossii immaculatum*, the grandly-coloured O. Queen Alexandra var. Carmen; and the fine *Miltonia Clowesii Rosefieldensis* of DE B. CRAWSHAY, Esq. (gr. Mr. Stables); *Sobralia Lowii* of HENRY LITTLE, Esq. (gr. Mr. Howard); *Phaius Doris* of NORMAN C. COOKSON, Esq. (gr. Mr. H. J. Chapman); the fine yellow *Brasso-Cattleya Mrs. J. Leemann inversum*—the first cross with *Brassavola Digbyana* as a seed-bearer, from the raiser, R. G. THWAITES, Esq. (gr. Mr. Black); *Cypripedium G. F. Moore*, C. Bridgei, C. Leeann Corona, and *Dendrobium Phalaenopsis Phyllis Moore* of G. F. MOORE, Esq. (gr. Mr. Page); *Cattleya labiata Captain J. F. Laycock*; *Cypripedium Actæus superbum* of DREWETT O. DREWETT, Esq.; C. Actæus, Bank House variety, of S. BRIGGS BURY, Esq.; the very handsome and distinct *Cymbidium Lowianum*, Fir Grange variety, of W. A. BILNEY, Esq.; *Dendrobium Arthur Ashworth* and the singular *Trevoria Chloris* shown by ELIJAH ASHWORTH, Esq.; the stately *Cypripedium Harri-Leeannum*, Park Lodge variety, of E. ROBERTS, Esq.; the very singular and ornate

Luddemannia Pescatorei, and the dark-coloured *Maxillaria nigrescens* shown by Miss WILLMOTT; and *Cattleya Hardyana Rex* from the Marquis DE WAVRIN.

(To be continued.)

MARKET GARDENING.

LILY OF THE VALLEY FOR SMALL GROWERS.

AN impression is abroad amongst some growers that unless this plant is cultivated by the several hundred thousand or even millions of crowns, no satisfactory profit can be obtained, but this idea is erroneous and rather surprising considering how easily and how successfully they are grown. No expert knowledge is required, no specially constructed houses, and no special sources of supply are needed. Taking one year with another, there is probably no more profitable plant to cultivate, and certainly none that is disposed of more easily, whether to local shops, to a private buyer, or to place on our large markets for sale on commission. If a shop or market trade is to be catered for, the first essential is to make provision for a regular weekly supply without any serious breaks. If an arrangement is made with a reliable firm, the plants can be had in bloom every week in the year, now that the retarding process has been brought to such perfection. At least one of the Hamburg exporting firms put up retarded crowns in as small a quantity as a thousand per case, and these are delivered weekly, fortnightly, or as may be required. Owing to their promptness in handling retarded crowns and the care with which they are packed, hardly any are spoiled through thawing too rapidly in transit, except perhaps in the hottest part of summer or when the boat gets delayed in crossing from Hamburg, and in these cases the firm always make good any losses. There is one particular branch of Lily growing which, in the opinion of many market-salesmen, is capable of considerable expansion, and that is the pot-trade for room and decorative purposes. When well grown with good foliage, there is no better subject to make an attractive plant in 48's and 32's. This trade is not catered for in half sufficient quantities. The writer has frequently seen such plants realise half-a-crown a pot.

Growers with only a small amount of glass will be well advised to take up the culture of Lily of the Valley, and to cultivate both the retarded crowns, a batch of which should be started into growth regularly each week of the year, and the fresh crowns, which can be forced from Christmas until the end of March.

As to cultivation, this is a matter needing very careful attention, coupled with a general knowledge of the usual methods employed. The crowns are received from abroad during the months of November and December, and can be forced into growth in order to bloom from Christmas to the end of March. These crowns can either be packed in damp moss and stored in a cold place, or they can be trenching-in (without parting the bundles) in the open ground. Frost will not in any way injure the growth; in fact, some growers say it is necessary they should be subjected to frost before they can be forced to the best advantage. They can be potted or boxed in quantities as required. The boxes should be made about 5 inches deep, and the crowns given about 2 inches space each way in planting. Any good, clean and sweet garden soil is suitable as a potting medium, if made freely porous by the addition of sand; and, if necessary, this soil can be used many times over, provided it is allowed to stand in a heap and turned over occasionally to sweeten before it is used again. Each time a little fresh soil may be added as occasion may require. Place the boxed crowns under glass in a very dark place: under a

bench is the usual situation, with a hempen screen to further keep out the light. The atmospheric temperature for the first two or three days should be of about 70°, after which it may be kept at 90° continuously. As soon as the flower spikes and some foliage show themselves, the plants can be placed on the top bench, and the bench or space below be filled up with another batch of crowns, but at no time should they be exposed to much light. The house should be heavily shaded with hemp-sacking on the outside. Whilst they are growing on the top bench they should still be grown in from 80° to 90° of heat, and when the flower spike is well expanded a lower temperature of about 60°, or even less, will be suitable. If they are not hardened off in this manner they will not stand cutting so well and the spikes will not last so long in water, nor will they stand up so stiff and straight.

The cultivation of retarded crowns is on many points different to that adopted for the fresh ones. The soil, type of boxes, and the system of culture in the dark are the same, but in the matter of temperatures a great difference exists. Retarded crowns should not be grown in more than 60° of atmospheric heat, and they should never be subjected to bottom heat. For fresh crowns placed under benches bottom heat is most suitable, but with retarded plants heating by means of pipes running down the paths and not directly under the benches is the most suitable plan. The fault with this system is that it subjects the crowns to too much heat. Growers are apt to lose sight of the fact that retarded crowns do not require forcing, but rather checking in growth after they are taken from the ice. The buds are ready and impatient to grow in a normal temperature without artificial heat. If, when the crowns are received from the refrigerator, they are not thawed, this should be done gradually, and in summer an outside shed is the most suitable place, but in winter a position such as under a greenhouse bench or elsewhere in which the temperature is about 45°. After the crowns, both fresh and retarded, are boxed and growing, they require during the whole period of forcing an abundance of water at the roots; the atmosphere of the house must be kept constantly damp, and the floors and pathways wet.

As to the crowns themselves, they may be divided into at least five distinct types—fresh crowns for very early forcing, fresh crowns for very late forcing, retarded crowns required for use from April to August, retarded crowns required for use from September to December, crowns required for pot-work, and such crowns as will produce a quantity of healthy dark green leaves. In the case of an inexperienced beginner it would be better to leave the selection of samples to a trustworthy firm, first informing them for what purpose the roots are required, and the grower will speedily gain sufficient experience to know which samples suit his purpose the best. As a general rule it is better to avoid samples retarded in England. These are usually frozen in public cold stores with provisions and other goods, and this kind of cold air is unsuited to retarding Lilies of the Valley, and according to the writer's experience (which covers handling about two and a half million each of both fresh crowns and retarded) nine out of ten batches grown from English retarded crowns are a dismal failure. In Hamburg they are retarded in specially constructed houses, and one or two firms have made a special study of the work, have their own cold stores, and have brought the business almost to perfection. E. C.

FLORISTS' FLOWERS.

THE RECENT MARKET-CHRYSANTHEMUM SHOW.

THIS exhibition, which was fully reported in the *Gardeners' Chronicle* for Dec. 15, has now become an annual event. As an educational lesson in the selection of varieties

for mid-December, the show was most valuable, and for the benefit of those who had not the opportunity of inspecting them, I will briefly refer to the more prominent varieties. As a rule the Japanese varieties are most in request for decoration, owing to their size, which is large enough without undue coarseness, and, as a rule, for their most brilliant colours. The incurved section was much more interesting than many persons would imagine. The single-flowered varieties were disappointing, the colours appeared dingy, and the blossoms did not show themselves to the best advantage. The peduncles of the majority in this section were weak, and not sufficiently stiff to support the blooms adequately. In the Incurved section the variety Frank Hammond, with its rosy bronze, medium-sized, neatly-built flowers was much in evidence, clearly proving its value for decoration in a mass in vases when not too tightly arranged. Mrs. Judson, with its pure-white, shapely blooms, was conspicuous on several stands. Buttercup, of a soft yellow shade of colour, was a variety much appreciated. The late-flowering Snowdrift, with its neatly incurving florets, was seen to advantage in a mass. Of the incurving Japanese type Madame Paolo Radaelli and its sport were conspicuous, the former heavily flushed with pink, and the latter having much more rosy bronze than is usual earlier in the season. The deep pink of Mdle. Lawrence Zede could not be other than appreciated, especially when arranged in conjunction with other suitable shades of colour. Mrs. T. W. Pockett, with its none too severely incurving florets, was raised in Australia. Guy Hamilton was quite one of the best white-flowered varieties. I strongly commend this to all gardeners who cater for a Christmas supply of white flowers. Needless to say, the Princess Victoria family were much in evidence, the creamy white shade of the type, and the golden and pink sports were all finely developed. Matthew Hodgson, with its crimson-brown florets, is certainly a good market variety, although it is no longer a favourite for exhibition purposes.

Amongst yellow kinds Nagoya was the most brilliant, yet the ordinary gardener scarcely ever grows this fine sort, but he would do well to make its acquaintance, for it is of a glorious hue. In the pink-coloured section Mdle. Louise Charvet was attractive; the shapely blossoms are borne on stiff, erect stems, and it is most useful for vase decoration. Framfield Pink has a lovely rose suffusion, enhancing the natural pink of the variety. Amongst richly-coloured sorts, Violet Lady Beaumont was noted; its deep, rich crimson is a most pleasing colour when associated with white and yellow. Cullingfordii had many admirers, and deservedly so. Mr. J. Thompson and its yellow sport had to be seen to be admired. E. Molyneux.

HOW TO PACK CHRYSANTHEMUMS FOR TRANSIT.

A CORRESPONDENT in St. Kitt's writes to the *Agricultural News* (Barbadoes, West Indies) as follows: "Young plants can be obtained from growers in England or America about August. The growers usually pack them in the same way as for transport in temperate regions. This gives very bad results, all the leaves and the young stems arriving in a rotten and mouldy condition. The growers should be instructed to pack as follows: Choose young plants which have formed woody stems; cut off nearly all the leaves and prune all the soft stems; wrap a very little wet sphagnum round the roots, and envelop the whole in about five loose folds of paper, some of which may be glazed, but not waxed. Do not use any box, and a paraffined box is the worst of all. If a box must be used, trust to paper wrappings for keeping moist, and cut the box full of holes."

The Week's Work.

[We do but echo the feelings of our readers when, on this occasion, we take the opportunity to tender our most appreciative thanks to those who have throughout the past year contributed to *The Week's Work*. The record of the experience of such men is of the greatest value to their fellow workers. If each year we make certain changes it is simply with the view of giving others the opportunity of expressing their opinions, and thus ensuring variety and freshness. In this issue also we introduce a new section devoted to the management of public parks and gardens. Happily for the health, bodily and mental, of the dwellers in cities, the municipal authorities of late years have devoted much attention to the formation and maintenance of recreation-grounds, using that word in its widest significance. Some years ago we made enquiries of medical officers of health in various cities as to the relation between the area of open spaces and the health of the population. The results were never published in full, but they were conclusive as to the great value of these breathing spots to the community, especially to the children. But the workers have also to be considered, and the requirements of the aged have to be provided for, so that while an open space is the main essential, its decoration as an agent in securing mental health and in developing the pleasures and amenities of life is hardly less important. The duties and requirements of the managers of these establishments are necessarily somewhat different from those of the gardener in general, hence we are pleased to have been able to avail ourselves of the services of Mr. W. Pettigrew, of the Cardiff parks, in initiating a series of articles, to which we trust our many friends among park superintendents will contribute from time to time. The selection and management of trees, the formation and maintenance of lawns, cricket grounds, golf courses, the treatment of lakes, the hatching and rearing of fish, the filling of flower-beds, the management of municipal allotments—all these will, we hope, come under consideration, at intervals, and form a valuable feature in the pages of the *GARDENERS' CHRONICLE*.]

PUBLIC PARKS AND GARDENS.

By Mr. W. PETTIGREW, Superintendent of the Parks and Open Spaces in the City of Cardiff.

Introduction.—At the present time, I believe, no medium exists whereby parks-superintendents can be kept in touch with each other's doings, and information on park-management can only, as a rule, be obtained by writing direct to the various public departments throughout this country. In this connection, it is interesting to note that the parks-superintendents in

the United States issue and circulate among themselves at given periods of the year a type-written bulletin, each superintendent adding a page or so of matter before passing it on to his neighbour. To my way of thinking, this at the best is but a cumbersome and unsatisfactory method of keeping up professional intercourse, and one which would hardly be found to work smoothly in the old country.

The decision of the Editor of the *Gardeners' Chronicle* to set aside a small space at intervals for the consideration of public park matters should be welcomed as the first step in attempting to meet our requirements. It is worthy of remark that one rarely finds parks-superintendents writing much to the gardening Press. While this may be largely accounted for by the fact that their time is so fully occupied, it may also be that the subjects most generally considered in the horticultural papers are not those upon which they may feel justified in giving an opinion. With a corner of the *Gardeners' Chronicle* placed at the disposal of parks superintendents, they may now be more inclined to write and give expression to opinions upon their own special work.

Although the chief official of a public parks department must be primarily and essentially a practical horticulturist, many of his duties, and the matters which call for his daily attention and thought, are more or less removed from the sphere of gardening, and come but little within the purview of the duties of the private gardener. As the conception of the uses to which public parks may be put becomes more extended and rational, these—from the purely gardening aspect—extraneous duties become a decidedly important part of the park superintendents' calling. Such matters being those which are never touched upon in the gardening Press, they will, all being well, be among the principal topics discussed in this column.

Preparation of estimates.—One of the important duties of the head of a parks department is the preparation of estimates, showing the probable cost of carrying on the work of his department for the period of six or twelve months, as the case may be. As rates are levied on the strength of these estimates, it is but natural that they are very carefully considered by the governing body of the town, and it is therefore necessary that they should be prepared thoroughly and well, and in as detailed a manner as possible. The municipal financial year, commencing as it does on April 1, makes it essential for all estimates to be sanctioned by the various committees concerned, and passed on to the finance department several weeks before that date; hence the commencement of the New Year generally finds park-superintendents busy preparing such estimates.

Where estimates are drawn up every six months, they are not nearly so difficult to prepare as where they are made for a whole year at a time. In the latter case—which is now the more common system—much foresight and care is required in their compilation, otherwise it will be found that before the year is out many additional expenses, which ought to have been foreseen and provided for, have been incurred, and the estimate over-spent. Under these circumstances the finance and controllers' department has a perfect right to ask the reason why.

It need hardly be pointed out that unless some systematic preparation is made for the drawing up of park (as any other) estimates they cannot be entirely satisfactory, as it is almost a matter of impossibility to make anything like ample provision for a year's requirements by simply considering the matter a day or so before preparing them. As a help in this direction, it is a very good plan to have a book in which notes may be made all the year round about matters requiring attention in the near future, especially such matters as may require extra outlay, as, for instance, the re-metalling of roads, the repairing of walls, and the renewal of fencing. It is the making provision for such cases as these, and not the usual maintenance charges, which are so apt to be overlooked in preparing an estimate. Then, again, it often happens that the committee in charge of the parks gives instructions at one season of the year to carry out certain work at another period of the year, for which money has ultimately to be provided. A memorandum of all such instructions, with the probable cost of carrying them out, should be kept in the same book, which would thus be an invaluable aid in preparing comprehensive and reliable estimates.

Estimates should be more or less binding.—Having prepared his estimates, the next important duty for a park-superintendent to do is to keep within them. Here, again, the use of a special book will be found to be of the greatest possible assistance. In this book—known as an Estimate Book—every item of the estimate, with the amount of money allowed for it, is entered up, and as bills are passed month by month the sums charged against each item are shown in such a way that it is easy within a few minutes to see how much has been spent on any part of the estimate. With the exercise of forethought in their preparation and a firm hand in afterwards dealing with them, it ought to be fairly easy to keep within one's estimates, but unfortunately it often happens that some new development never dreamt of takes place, and with all one's care and manipulation the year's estimate gets sadly upset. Notwithstanding the fact that one often hears it asserted that the "public's pocket is deep," it

behoves every park-superintendent to have as his motto, "Efficiency with economy," and the more he is able to carry this into effect, the better for himself and the public.

THE HARDY FRUIT GARDEN.

By Mr. J. MAYNE, Gardener to the Hon. MARK ROLLE, Bickton, East Devon.

Retrospection.—A new year usually brings new readers who have not previously consulted the remarks in these pages on seasonable work; while, therefore, endeavouring to avoid repeating advice penned by my predecessor, a little latitude may perhaps be extended to me for the reason I have stated.

Planting trees.—Trees that are planted before the shortest day in the year have the best

chance of establishing themselves before they are subjected to the parching winds of early spring and the drought of summer. At the same time, if the work is carefully carried out when the soil is in a friable condition, planting may be continued during the next six or

eight weeks with every chance of success, especially if attention be first given to those varieties of fruit that come into flower or leaf early in spring. The mistake is frequently made of cramming the roots of a tree into too small a hole instead of allowing ample space that they can be spread out evenly. In many instances trees are planted too deeply, 3 to 4 inches deep of soil over the uppermost roots being quite sufficient. The affording of stakes to newly planted trees is often delayed until the winds show that the tree has been rocked to and fro, and therefore the roots loosened in the soil. Such supports as are necessary should be afforded at the time of planting; the affixing of a permanent label also is sometimes neglected until the nurseryman's temporary writing is effaced, to the disappointment of the planter.

Pruning.—The exceptionally mild weather of the past two months has been favourable for this work, but in many gardens such work extends well into spring. That remaining still to be done should be pushed forward at every opportunity, cutting back beyond the summer pruning, and within two buds of their origin, the shoots on Apple, Pear, and Plum trees, whether standing in the open or trained against walls. More latitude may be allowed the extension shoots, these being cut back to one-third their length. Exceptions may be made in respect to horizontally trained trees, leaving such shoots as they are if not more than 12 inches of growth has been made during the past year. It is well to survey an established tree and see whether an improvement cannot be effected by reducing the number of spur growths; these, after some years, become far too numerous, obstructing sunlight and air. Defer, for the present, the pruning of recently-transplanting trees.

Grafting.—Where grafting is contemplated, the required varieties should be selected, labelled, and the scions laid or heeled-in under the shelter of a north wall. The trees to be grafted should be clean and healthy specimens, and should be headed back to within a few inches of the point where it is intended to insert the scions.

Grease bands.—Those who apply grease bands to catch the winter moth should examine these, and if found dry smear them afresh, after rubbing off the trapped moths. The birds, too, will soon be busy among the fruit buds, and prevention being better than cure, let those trees and bushes which have already been pruned, be netted, or syringed with Bentley's Bud-protecting composition two or three times before the buds begin to unfold.

THE FLOWER GARDEN.

By A. C. BARTLETT, Gardener to Mrs. FORD, Pencarrow, Cornwall.

Local conditions.—As the application of all advice offered in a calendar of out-door gardening operations depends largely on the local conditions of climate, it will be useful to state briefly the approximate conditions in these gardens. The north and north-east portion of Cornwall does not enjoy the advantages of the south and western parts. As a matter of fact, the former district is far from being the "Cornish Riviera" so largely ad-

vertised by the railway company whose system carries so many tourists and health-seekers to the west of the county. Except that the average rainfall (43 to 47 inches) is greater, and gales are more frequent, the conditions are very similar to those around London. Frequently the mean temperature is lower than in London. At the moment of writing snow is on the ground, and we have registered 12° and 14° Fahr. of frost. This difference in climate from the more favoured half of the county, where a surprising variety of Palms, shrubs, and plants (which in most parts have to be grown under glass) are quite at home, is due partly to altitude—Pencarrow is over 400 feet above sea level—and chiefly to the absence of the warming influence of the Gulf Stream, which, after approaching the Scilly Isles, divides at the Lizard and Land's End. The portion which continues up the Irish Sea passes across the Bristol Channel, giving to the north coast of Cornwall only a part of its benefit, and consequently this neighbourhood not only is unable to sustain sub-tropical vegetation, but its seasons are late. The influence of the nature of the soil is everywhere of such a local character that it does not call for any special mention here.

FRUITS UNDER GLASS.

By ALEXANDER KIRK, Gardener to J. THOMPSON PATON, Esq., Norwood, Allra, Clackmannanshire.

Cleansing and pruning of vines.—Give daily attention to any Grapes which may be still hanging on the vines, removing all berries showing signs of decay. Do not allow the heat

to fluctuate, but keep the atmosphere somewhat dry. Complete as soon as possible the pruning of all vines from which the fruit has been removed. I do not recommend close pruning especially if the vines are weak. Leave two buds at the base of each shoot, one of which can be rubbed off when the vines start into growth. All vine rods, after they have been pruned, require to be thoroughly washed with hot water and Gishurst compound whether they have been infested with insect pests or not, but they should not be peeled unless they have been attacked with red spider, bug, &c. Wash and cleanse thoroughly all the woodwork and glass, and paint the woodwork if this is necessary.

Remove the loose soil from the surface of the borders right down to the roots, making bare some of the latter. When this has been done, apply a top-dressing with fresh loamy soil, in which has been mixed some approved vine manure, and mulch the surface with moss-litter or manure from an old Mushroom-bed, placing the material 1 or 2 inches thick. When this has been done, tie the rods into position, and the house will then be ready for starting when desired.

Vine "eyes."—The present is a suitable time to put in vine "eyes" for raising young rods or planting in borders, &c., or for in-arching in old vines.

Early vines that were started last month will now be on the move, and require careful attention. The atmospheric temperature at night should be 65°, and during the day 70°. Prevent any excess of moisture, and do not hurry the vines during these short, dull days. When the buds on the spurs are breaking into growth, rub out all but the best one. If the early vines are growing in pots, be careful to keep the roots supplied with sufficient water. Disbud the young canes carefully.

Pines.—If ripe fruits will be required early in the season, it will be necessary now to select a sufficient number of "Queens," choosing the best, well-set plants, which, having finished their growth, have also been rested. The plants will require an atmospheric temperature at night of 65°, and by day 75°. Plunge the pots in a "vine-pit" in a bed of tan-bark or any suitable lunging material, and see that the bottom heat is at about 85°. The soil in the pots will be dry, therefore give the roots a good soaking of water at a temperature of 75°. Gradually increase the amount of heat and moisture as the days lengthen. Attend to young suckers intended for succession, but keep them much cooler. The over-watering of Pines at this season of the year is more than usually injurious.

PLANTS UNDER GLASS.

By J. G. WESTON, Gardener to H. J. KING, Esq., Eastwell Park, Kent.

Temperatures.—In the stove the atmospheric temperature at night should now range between 50° and 65° Fahrenheit, the greater heat mentioned being the maximum for a mild night, and the lesser heat the minimum for a cold or windy night. A rise of 10° should be allowed in the morning before any ventilators are opened, endeavouring to have the conditions favourable for admitting a little air during the latter part of the morning if the weather is good, but it will be necessary to close

the houses again early, thus making the most any sunshine there may be. Watering should be done as early in the day as possible, care being taken not to have too much moisture out late in the day.

In the warm flowering-house, containing such plants as Gesneras, Euphorbias, winter-flowering Begonias, &c., the atmosphere should be kept rather on the dry side, and at a temperature ranging from 55° to 60° at night, rising 5° higher in the daytime; admitting a little whenever practicable. The ordinary flowering-house or conservatory may be kept at about 5° at night, and 55° in the day, this degree of heat being suitable for Cyclamen, Primulas, and forced bulbs and shrubs that are usually seen in such structures at this season, also such plants as Grevillea robusta, Cordyline indivisa, Acacias, Cytisus, and others, which may be used with advantage in conjunction with the wintering-plants mentioned above.

Winter-flowering Carnations.—Where a house devoted to this most useful class of winter-flowering plants, it is at the pre-

sent time, one of the most interesting houses, as a succession of blooms is now rewarding the careful cultivator. The blooms are general favourites, and can scarcely be used in the wrong place, whether for decorating the dining-table or in glasses about the sitting-rooms, their long, elegant stems making them particularly valuable for such work. Some of the best varieties at present are Enchantress, and the various sports therefrom, Lady Bountiful (pure white), Harlowarden (deep crimson), White Lawson and White Perfection, both beautiful varieties, Crusader (scarlet), Flamingo, Robert Craig, Nelson Fisher and Dorothy Witney, while the older Mrs. S. J. Brooks, Mrs. T. W. Lawson, Alpine Glow, Floriana, Fair Maid, and Mrs. Leopold Rothschild, make a very good collection. The atmospheric temperature of this house should range from 45° to 50°, and a little air should be admitted whenever the temperature out of doors is above freezing point, keeping at the same time a nice warmth in the water pipes.

THE KITCHEN GARDEN.

By WILLIAM HONNESS, Gardener to C. COMBE, Esq., Cobham Park, Surrey.

Preparation of ground.—In consequence of the very open weather which continued through November and the greater part of December, the work of trenching, digging, &c., should be by

this date in a well-advanced condition, and certain plots and borders have probably been marked out for particular crops. Trenching should not be proceeded with in very hard weather, as it would be found that large pieces of frozen soil, if buried in the ground,

are a long time in thawing, and until a considerable time after this has taken place the ground remains in a cold, wet condition.

Rotation of crops.—The arrangement of the crops is important. It is good practice to alternate tap-rooted crops with surface-rooted vegetables. Plots now destined to carry early Peas, Beet, Turnips, Carrots, and early Salads could ultimately be followed by Cabbages, Broccoli, or similar crops.

Forcing Vegetables.—Of Potatoes, the Jersey Fluke, which is imported into this country in May and early June, has yielded splendid results here in November and December. Well selected "sets" that were obtained in the manner already stated were at once given full exposure to the sun to hasten their ripening, previous to being started in boxes which were partly filled with leaf-soil and placed in a cold frame facing to the south. They were kept fairly moist at the roots, and air was admitted moderately to the frame. Full exposure to the sun ensured good, strong growth, and the tubers had made an abundance of roots by the middle of August. The first batch was planted at about that date in light, leafy-soil in a cold frame, but with sufficient heat at command for use when required to repel frost. Tubers of good quality and weighing about 2 ounces to 3 ounces were thus ready in considerable quantities for consumption by the end of November. Sharp's Victor forms a good succession to this variety, but, although superior in quality, does not appear quite so prolific.

Peas that were sown in frames in November for yielding a crop by the end of May require to be ventilated liberally on all possible occasions. Stir the soil between the rows frequently to prevent the least suspicion of sourness on the surface. A successional sowing of seeds of such varieties as Sutton's Little Marvel, May Queen, and Early Giant should now be made.

Rhubarb.—Continue to lift roots for forcing in succession. If they are lifted and allowed to

remain on the surface of the ground, fully exposed to frost, thus receiving as decided a check as possible before introducing them to heat, they will usually be found to respond more readily to the influence of the forcing-house.

Seakale may be forced with excellent results on the established beds, if the leaves are removed in autumn as soon as they are decayed, giving the crowns every facility to become thoroughly ripened before covering them with the pots. A good depth of well-mixed litter and leaves must be placed over and about the pots to secure perfect darkness, and a moderate heat of from 45° to 48°. As a number only of the plants will be required for forcing at one time, the remainder should be protected with a covering of leaves to prevent the ground becoming frozen, for if this were to happen greater heat and a longer period would afterwards be required to induce the plants to grow.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir Trevor Lawrence, Bart., Burford, Surrey.

Temperatures for New Year.—In Orchid culture, the advent of a New Year makes but little difference, and the present period may be taken as the centre of the resting, or slow-growing season.

But there will probably be some gentlemen who will now for the first time enrol themselves among Orchid amateurs, more beginners, added to the ranks of us Orchid growers, and as they become interested in the work which is done in the "Orchid Houses," many will, in all probability, become

new readers of the *Gardeners' Chronicle*. For the benefit of such, it may be well to state that I group the various structures in which Orchids are grown into four divisions, viz.: (1) East Indian house; (2) Cattleya house; (3) intermediate house; and (4) cool or Odontoglossum house. For maintaining good health in the plants at this season of the year, the atmospheric temperature at night in the aforesaid divisions should be kept at about (1) 60° to 65°; (2) 55° to 60°; (3) about 55°; (4) 45° to 50°. A few degrees less of heat than the lower figures indicated during exceptionally severe nights, when the houses, owing to the unusual amount of fire-heat, are comparatively dry, is much better for the health of the plants than high, desiccating temperatures. The higher degrees of heat should be maintained whenever the external temperature ranges between 30° and 40°. By day the higher figures mentioned should be adhered to, and whenever the temperatures can be raised several degrees by sun-heat, the plants will be greatly benefited thereby, providing the atmospheric conditions inside are carefully regulated as regards moisture and the necessary amount of fresh air is admitted through the ventilators. In the four divisions mentioned above almost every tropical Orchid can be grown more or less well, but where large numbers of certain species have to be grown well, it is advisable to give them a structure to themselves. Thus in many places there will be a Phalaenopsis house, a Dendrobium house, a Mexican house, a Cypripedium house, a Masdevallia house, and houses set apart entirely for the raising and growing of Orchid seedlings. If any reader who may possess only the first-named divisions should find me at any time recommending some particular plant or any section of Orchids to be grown in any of the more specialised houses, he will, without doubt, by careful study, find suitable positions in some part of his houses almost identical with those advised.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

Illustrations.—The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.

APPOINTMENTS FOR JANUARY.

TUESDAY, JANUARY 8—
Roy. Hort. Soc. Coms. meet.
Ann. meet. Scottish Hort. Assoc., Edinburgh.
Brit. Gard. Assoc. Ex. Council meet.

THURSDAY, JANUARY 10—
Manchester and N. of Eng. Orchid Soc. meet.

MONDAY, JANUARY 14—
R.H.S. Exam. of Public Parks and Gdn. Employees.

THURSDAY, JANUARY 17—Linnæan Soc. meet.

TUESDAY, JANUARY 22—Roy. Hort. Soc. Coms. meet.

THURSDAY, JANUARY 24—
Gardeners' Roy. Benevolent Institution Ann. Meet. and Election of Pensioners at Simpson's Restaurant, Strand, London, 2.45 p.m. Friendly Dinner at 6 p.m. Manchester and N. of Eng. Orchid Soc. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—37.9°.

ACTUAL TEMPERATURES:—

LONDON.—Wednesday, January 2 (6 P.M.): Max. 44°; Min. 39°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, January 3 (10 A.M.): Bar., 29.8; Temp., 43°; Weather—Bright.

PROVINCES.—Wednesday, January 2 (6 P.M.): Max. 44° Ireland S.W.; Min. 36° Scotland N.

SALES FOR THE ENSUING WEEK.

MONDAY AND FRIDAY—

Herbaceous and Border Plants, Azaleas, Rhododendrons, Roses, Hardy Bulbs, &c., at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.

WEDNESDAY—

Hardy Border Plants, Perennials, Lilliums and other Bulbs, at 12; 5,000 Roses, at 1.30 and 4; Palms, Plants, Azaleas, &c., also Fruit Trees, at 4; 2,004 cases Japanese Lilliums, Lily of the Valley, Hardy Bulbs, &c., at 1, at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

Dutch Bulbs and Flowering Plants, at Stevens's Auction Rooms, 88, King Street, Covent Garden.

FRIDAY—

Various Importations of Orchids, also Established Orchids in variety, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

The American Gooseberry-mildew.

We learn that Prof. Salmon, who has already favoured us with sundry communications on the subject, is to lecture at the R.H.S. on Tuesday next on this fungus. Mr. Salmon is an enthusiast whose ability and pertinacity command admiration as well as attention, and his lecture detailing his experience will be listened to with interest commensurate with the importance of the subject. In the evening of the same day Mr. Salmon is to speak on the same subject at the meeting of the Horticultural Club. If this were all, we might confine ourselves to the mere announcement of what is to take place, but from a circular of the Market Gardeners', Nurserymen's, and Farmers' Association we learn that that association "has arranged with the R.H.S. for a joint meeting to discuss the subject," and not only that, but the discussion is expressly stated in the circular to be conducted "with a view to such further action as it may be decided the interests of the trade call for." Free discussion can do no harm and may be productive of much good, but the implied undertaking to take further action

would seem to be an attempt to commit the R.H.S. to a certain course which may, or may not, be desirable. For our own part, we trust the society, as a society, will not at present take steps to sanction anything more than discussion, for the reason that whilst we all admire the enthusiasm and pertinacity of one expert, we must also see to it that that enthusiasm is tempered with discretion. There is, so far as we know, no reason to doubt the accuracy of Mr. Salmon's facts, but it is by no means so certain that this observer is not attaching an exaggerated importance to them. In principle Mr. Salmon is no doubt correct, but the state of affairs as revealed in the laboratory and by inspection of specimens in various parts of the country does not justify the application of abstract principles to the vastly different and, it may be, conflicting conditions of the fruit-garden. So many factors have to be taken into consideration that it is quite possible that the drastic measures which would be dictated—and, from his point of view, rightly so—by the scientific expert might in the end, if carried out, be productive of more harm than good to the fruit-grower. The most drastic measures enacted in the case of the Phylloxera failed to prevent the spread of the pest, whilst they inflicted a vast amount of quite unnecessary inconvenience and loss to those who were not connected with the vine-growing industry. We cannot suppose that any system of inspection of imported plants, or any destruction of gooseberry bushes known to be infested, would entirely prevent the progress of the disease, though, undoubtedly, they might check it and diminish the mischief caused by it. If expert opinion were unanimous, there would be no doubt as to the propriety of the most stringent measures being taken to cope with the disease whilst it is yet in the initial stage, or, better still, to prevent its re-introduction. But expert opinion is clearly not unanimous, and measures of prevention are already too late, unless locally. Mr. Massee, the expert appointed by the Board of Agriculture to examine into the matter, evidently does not take so serious a view of the case as Mr. Salmon does, and, in this opinion, he is, as we know, supported by other men of science. When the matter was brought recently before the Scientific Committee at which were present various experts and a contingent of naturalists and practical growers, a resolution proposed with a view of some action being taken was not even seconded, doubtless because the members of the committee felt that the subject had not yet got beyond the discussion stage. In these circumstances, it might be well if the R.H.S., before definitely committing itself to any particular line of action either by itself or in association with any other body, should appoint a small sub-committee selected from the Scientific and Fruit Committees to consider and report to the Council. The two committees we have named comprise several members, among them Mr. Salmon himself, Mr. Massee, Mr. Güssow, Mr. Chittenden, and others peculiarly well fitted either to furnish evidence, or to pronounce an opinion on that which we have already. A vote taken at an ordinary meeting comprised largely of those unfamiliar with the subject, would have little real value, though outsiders might naturally attach importance to it.

Hypodermic Injections in Plants.

M. J. M. Simon has been making experiments on his property in Morbihan by injecting nutritive fluids into the stems of trees and other plants. A receptacle containing the fluid to be injected is placed at some height, 2 metres in one case, above the ground level. From this a pipe is carried down nearly to a level of the soil just above the roots, a little funnel-shaped curved tube is attached to the base of the pipe, and made to penetrate to the young wood of the tree. In this way a certain amount of pressure is established and this is of course aided by the sap rising from the root. Decaying Apple trees were thus treated with encouraging results, and in the *Journal de la Société Nationale d'Horticulture de France* M. Simon gives the details of further experiments of a similar kind on Peaches, Vines, and Potatoes. In the case of the Peach purin was injected, mixed with water (the proportions are not given). The injected tree was side by side with one in a similar state of decrepitude but not treated. The results were soon apparent, the injected tree grew vigorously. The experiments were conducted over two years, sometimes with purin, sometimes with nitrate of potash, sometimes with a chemical solution of a composition closely resembling that of the sap. Not only was the vigour restored, but Peach trees that had previously been attacked with blister dropped their leaves and produced new ones which were unaffected with the fungus. In the case of Vines an injection of copper sulphate did harm owing, probably, to it being used in a not sufficiently dilute condition, but ultimately, by the aid of copious waterings, the leaves partially recovered themselves, and at the end of the experiment neither Oidium nor mildew was to be seen either on the foliage or on the berries. Cabbages, Cauliflowers and Potatoes were treated in the same way, the receptacle containing the liquid to be injected being placed at a height of 3 or 4 feet above the collar which is pierced by a funnel-shaped cannula in the same way as in the case of the trees, an indiarubber pipe connecting the receptacle above with the cannula below and permitting the entry of the liquid into the tissues of the plant.

We must refer to M. Simon's paper for the full details. We have said enough, we hope, to induce our experimenters to set to work. Assuming the correctness of M. Simon's conclusions, the treatment of "Silver leaf," for instance, ought to be easy. The great difficulty would be to know in what proportions the iron sulphate, or whatever substance may be employed, should be used. This can be determined by experience only. Here is work for the scientific director at Wisley.

SINGLE-FLOWERED CHRYSANTHEMUMS.—

The introduction of varieties with newer and brighter tints in the florets, extreme freedom of flowering, and the fact that they can be had in flower both early and late in the season, have won for single Chrysanthemums much popularity, and their culture is becoming more general every season. Some of the flowers have a very symmetrical form, while in others the florets are more or less ragged in appearance, and still others have quite rolled or fluted florets. To this latter section belongs the pretty pink or mauve-coloured Thirza Cherry, shown at fig. 9, which is reproduced from a sketch by Mr. WORTHINGTON

FIG. 9.—SINGLE CHRYSANTHEMUMS MISS H. HAMPSON AND THIRZA CHERRY. (See page 8.)

SMITH, while the variety *Miss H. Hampson*, a beautiful white *Chrysanthemum* for which Lord ALDENHAM received an Award of Merit at the meeting of the Royal Horticultural Society, on November 20, belongs to the symmetrical type. The flower, however, loses none of its beauty from its regularity; it is not more regular than the Queen of the race, the beautiful flower named after MARY ANDERSON, which, although in cultivation for so many years, is still without a rival. The variety under notice has some likeness to the older favourite, and we should not be surprised if it is partly derived from that variety. The axillary flowers develop perfectly for one foot down the spray from the top bud and many of them are in flower at the same time. Other single-flowered varieties were illustrated in our issues for December 15 and December 29, 1906.

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the committees will be held on Tuesday next, January 8, in the Society's Hall, Vincent Square, Westminster, S.W. A lecture on the "Introduction of the American Gooseberry-mildew into England" will be given by Mr. E. S. SALMON, F.L.S., at 8 o'clock.

THE SURVEYORS' INSTITUTION.—The next ordinary general meeting will be held on Monday, January 14, 1906, when the discussion on the paper read by Mr. E. H. BLAKE (Fellow), on November, 26, 1906, and entitled "Some Notes on Sanitary Law," will be continued.

SOME OF THE PLANTS IN FLOWER IN THE OPEN AIR AT LA MORTOLA ON CHRISTMAS DAY.

—Sir THOMAS HANBURY writes as follows:—In the accompanying list of plants in flower here in the open, I have only included some of the more noticeable; a complete list would show a total of over 400. The season is normal; as yet I have seen no ice, and the temperature even in the early morning is generally about 40°; at many places along the coast rather sharp frost has prevailed, dealing death to the enormous quantities of Carnations now cultivated, not only by horticulturists, but also by small peasant proprietors.

—Thomas Hanbury, La Mortola, Christmas, 1906.

CHOISYA TERNATA.—We have before us a photograph of a plant of this beautiful shrub which was flowering in December for the third time in a garden near Hayward's Heath, Sussex. The shrub is some 10 feet in height, and is in a sheltered corner.

"WAKE-UP, ENGLAND!"—This famous exhortation was addressed by the PRINCE OF WALES to his fellow countrymen on his return from his travels. Our neighbours, the French, feel the same necessity, for at a meeting of cultivators interested in the cider industry, the cry was "*Reveillons nous!*"

THE BRANDEGEE HERBARIUM has been presented to the University of California by Mr. and Mrs. BRANDEGEE. It is especially rich in type specimens collected in Mexico and in California, and is the more valued as many similar specimens were destroyed in the great fire which ravaged the Herbarium of the Californian Academy of Sciences.

NICE.—The *Société Centrale d'Agriculture, d'Horticulture et d'acclimatation de Nice et des Alpes maritimes* is organising a great international exhibition of agricultural and horticultural products to be held in Nice from Wednesday, March 13, to Sunday, March 17 (both days inclusive). Schedules may be obtained on application to the secretary of the society at Nice.

POTATO DEMONSTRATION.—Messrs. SUTTON & SONS have issued a series of illustrations showing the results of the various experimental trials carried out last season near Reading, together with descriptive notes. We have on more than one occasion referred to these experiments, and need only now say how valuable is the record which Messrs. SUTTON have now presented to us. The differences between the typical *Solanum Commersoni* as grown under several conditions, and the violet form alleged to have arisen from it by "mutation" are well shown. Other experiments are in their way as remarkable, as, for instance, those showing the manurial value of withy rods and those intended to show the relation of tuber-formation and flower-production. *Epicure* (early) and *Up-to-Date* (late) yielded the heaviest crops in their respective sections. The comparative trials of crops derived from "seed-tubers" ripened in Scotland, Ireland, Lincolnshire, and South England show the advantage of Irish and Scottish "seed," probably because the more equable climate ensures a more gradual and continuous growth of the tuber. Experiments made to show the results of planting tubers known to be diseased need to be repeated before safe conclusions can be drawn. As to the size of the "set" which is most advantageous to plant, the results show that large sets (weighing, say, about four ounces) are the most productive, though where a large area has to be planted, medium-sized sets would be preferable. There were several other trials to which we cannot now further allude, unless it be to express the hope that they may be repeated in the coming seasons as nearly under the same conditions as before. We may then ascertain, other things being equal, what are the effects of variations in climate and season. In the meantime, we can but express our sense of the careful way in which the trials have been carried out, and of their very great practical importance.

SEED-POTATOS.—The Department of Agriculture, and technical instruction for Ireland, has lately issued a leaflet detailing the results of a further trial on the use of sprouted Potatoes in planting. These experiments on late varieties fully confirm those of previous years, and show a substantial increase in yield by the use of sprouted tubers. Numerous varieties were tested under like conditions, but the results were so practically uniform that they may be regarded as conclusive.

POTATOS.—The results of a comparative test of 51 varieties of Potatoes at Summer Hill, Mallow, Co. Cork, 1906, made by Mr. J. F. WILLIAMSON, of Mallow, have been made public. A single pound of each variety (divided into 12 sets, as far as possible of equal size, and all except 8 varieties, comprising 12 whole tubers) was planted 15 inches apart in drills 30 inches wide. All were planted on April 11, and with the object of testing relative resistance to disease they were purposely left unsprayed. All (Second Earlies as well as Maincrop) varieties were raised between September 10 and 20. The previous crop had been autumn-sown cabbage plants, following vetches on lea. Immediately previous to planting a mixture at the rate of 6 cwt. per statute acre, consisting of four parts superphosphate, and one part each of sulphate of ammonia and sulphate of potash, was sown on the drills over a medium dressing of farmyard manure. The yields have been certified by independent public men, who kindly supervised the raising on different dates. The consistency of the relative cropping power of some of the varieties during the four years over which these trials have extended is noticeable, as will be seen from the following table:—

	1906.	1905.	1904.	1903.
Duchess of Cornwall ...	2nd	1st	1st	1st
The Factor ...	5th	4th	9th	18th
Dalmeny Beauty... ..	6th	11th	4th	4th
Scottish Triumph ...	19th	10th	18th	12th
Carter's Snowball ...	10th	23rd	27th	26th
Black Skerries ...	42nd	30th	33rd	32nd
General Buller ...	41st	27th	24th	33rd

(In each year over 50 varieties have been grown.)

The following varieties showed more or less disease when raised. It must, however, be remembered that none were sprayed, and that the Second Earlies should have been raised sooner. Considerably diseased—Windsor Castle, British Queen, Ireland's Best, Great Scott, Diamond Reef, Dalmeny Radium, Maxim, Gold Reef, Old Champion, Carter's Snowball. Diseased—General Buller, Dalmeny Regent, Million Maker, The Colleen, Table Talk, Johnson's Diamond, Engineer, Lord Dundonald.

PRIZES FOR SHREWSBURY.—Messrs. W. BULL & SONS send us particulars of certain special prizes they will offer for collections of nine distinct kinds of vegetables to be exhibited at the Shrewsbury Show on August 21 and 22 next. The first prize will consist of a silver cup, value 5 guineas, and £6 in cash. There are six cash prizes which, together, amount to £17 10s.

ORCHIDISTS AS SURREY JUSTICES.—FRANCIS WELLESLEY, Esq., Westfield, Woking, and W. A. BILNEY, Esq., Fir Grange, The Heath, Weybridge, have been appointed Justices for the County of Surrey. JEREMIAH COLMAN, Esq., Gatton Park, is Chairman of the Reigate Division. All the gentlemen named are members of the Orchid Committee of the Royal Horticultural Society.

THE UTILISATION OF CANAL AND RAILWAY BANKS.—The area devoted to the cultivation of Apples, fruit bushes and nuts has been considerably increased in the vicinity of Berlin, by planting the banks, dams and strips of land of the Teltow Canal. Besides planting Apple trees and Currant bushes, experiments have been made to carry out the cultivation of Hazel nut bushes on the sloping banks, as hedges; and it is the intention to carry out the design on a large scale, and to carry the produce by water to the city, as being the most convenient and cheapest mode of transport. The same kind of planting will be initiated on the Royal Railway in the neighbourhood of Erfurt, wherever the land is suitable, the railway company supplying the trees or paying the cost if undertaken by others. Moreover, the use of the land so planted will be made over to the officials and workmen connected with the railway in small portions, free of charge for the term of five years, on the condition that they agree to carry out the cultivation of the land in a proper manner.

RUBBER.—Dr. WILLIS, in an article in *Nature*, gives an account of the introduction of the rubber tree (*Hevea brasiliensis*) to Ceylon, through the mediation of the Royal Gardens, Kew. In 1897 Dr. WILLIS, who succeeded our old friends and correspondents THWAITES and TRIMEN, in the directorship of the Peradeniya Botanic Garden, made the discovery that a second tapping of the tree made within 10 days of the first will yield a larger supply than that obtained originally. Only in the fifth successive week did the supply of latex fall below that obtained in the first week. From this it was calculated that in the tenth year a rubber plantation might show a profit of 27 per cent. In Ceylon at the present time there are more than 104,000 acres planted with rubber, principally the Hevea. Ceara rubber, *Manihot Glaziovii*, and *Castilloa elastica* have also been tried with more or less success, but none of the other rubber-producing trees have proved profitable. In the Malay peninsula, through the exertions of Mr. RIDLEY, 50,000 to 60,000 acres are devoted to the growth of the Para rubber (*Hevea*). Mexico is reported to have 20,000,000 trees of *Castilloa* on about 100,000 acres. The price of rubber has so greatly risen that the pioneers of the cultivation have reaped large profits, and there is a constant increase of growers anxious to participate in the good results. The rubber exhibition held recently in Ceylon has already been alluded to in our columns. "Taking it altogether, the creation of the now great rubber industry, and its rapid progress from very rough and crude methods to a highly progressive and scientific spirit, is entirely the work of the Botanical departments of Ceylon and Singapore, and they may justly pride themselves upon the result." This will find a universal echo, while a due share of the credit must be allotted to Sir WILLIAM THISSELTON DYER and the officials of the Royal Gardens at Kew.

"LE BAMBOU."—The December number of this periodical, exclusively devoted to matters connected with the Bamboos, either wild or cultivated, is before us. The articles give evidence of great knowledge of the subject and of extended research. Cultural details are not omitted, so that we may heartily commend the periodical to those readers conversant with the French language and interested in the history, culture, and uses of the Bamboos. Communications should be addressed to M. J. HOUZEAU DE LEHAIE, Ermitage, Mons, Belgium.

SOLANUM COMMERSONI.—At a Kochkunst Ausstellung (cookery exhibition), held at Cologne towards the end of last September, some tubers of this plant were shown by the cultivator, Hrn. GUSGRATTI, of Alfter, a hamlet situated on the hills near the city, and these were shown in the basket in which they had been grown. It was alleged that the species will succeed in any kind of soil, even in mud, the tubers growing half in the soil and half above the surface, and that they attain to an extraordinary size. The cropping quality of this horticultural wonder was said to be twice as great as that of any other known species. The British raisers of new varieties of Potatoes must bestir themselves, or the varieties "made in Germany" will excel their best productions.

SOLANUM COMMERSONI VIOLET (LABERGÈRE).—M. WELKER relates his experiences in the last number of the *Journal de la Société Nationale d'Horticulture*. He asserts that, having attentively watched the development of Labergère's variety growing intermixed with Blue Giant, but separately labelled, he had been unable to find any difference between the two at any period of the growth.

THE "BLANCARD" FUND.—Mr. C. HARMAN PAYNE acknowledges further donations to this fund, amounting to the sum of £4 12s. 6d.

THE PREVENTION OF CORRUPTION ACT came into operation on January 1 and will, we trust, contribute to raise the great industries of the country to a higher level. The lawyers will benefit in their endeavours to define what is "secret and corrupt," but the honest man will be safely guided by his own conscience, and may comfort himself by the reflection that a complimentary gift at Christmas or when some special service has been rendered is not likely to induce the Attorney-General or the Solicitor-General to sanction a prosecution unless the gift is "corrupt" in the sense of being given as a secret discount or in the hopes of receiving an order.

AN OLD SUBSCRIBER.—It was very gratifying this week to get a letter from M. TRANSON, of Orleans, who, for the 53rd time, sends us his annual subscription. Everyone at all familiar with continental establishments knows TRANSON, of Orleans, at least by name, and will, we are sure, join with us in hoping that for several years to come we may count him among our subscribers.

THE GREATEST FRENCHMEN.—Fifteen millions of voters have given their individual opinions as to the relative pre-eminence of distinguished Frenchmen. Somewhat to our surprise, we must own, but with infinite satisfaction, we find PASTEUR heading the list with 1,888,425 votes. VICTOR HUGO came next with 100,000 votes fewer; CURIE, PARMENTIER, ARAGO, and CHEVREUL are among the foremost. The French nation seems to have realised that there is some other form of "gloire" besides military renown, and that the greatest benefactor to humanity is the man of science and research.

THE LATE COUNT DE KERHOVE DE DENTERHEM.—All those interested in progressive horticulture, and especially visitors to the Ghent quinquennial, will realise the extent of the loss entailed on European horticulture by the death of the President of the Société Royale d'Agriculture et de Botanique de Gand. Many such persons will feel it a privilege to contribute towards the memorial which is to be erected in Ghent to perpetuate the memory of a man as remarkable for the number, variety and excellence of his public services, as for his personal character. Subscriptions for the above purpose may be sent to Dr. MAXWELL MASTERS, F.R.S., 41, Wellington Street, Covent Garden, and will be acknowledged in these columns.

ECONOMIC BIOLOGY.—We notice in the current number of *Nature* that at the annual meeting of the Association of Economic Biologists, to be held in Cambridge on January 9 and two following days, the following among other subjects are to be brought forward: Cereal Breeding by Mr. BIFFEN; New Hemipterous Fruit-Pests by Mr. F. V. THEOBALD; The American Gooseberry-mildew, by Mr. E. S. SALMON; The Successful Extermination of the Black-currant Gall-mite (big bud), by Mr. W. E. COLLINGE; The Geographical Distribution of the Principal Rubber-plants, by Mr. W. G. FREEMAN; The Spruce Gall and Larch Blight Disease caused by Chermes, by S. R. BURDON, &c.

Publications Received.—*Bulletin of Miscellaneous Information, Royal Gardens, Kew*. No. 8. 1906. Contents: Oil-grasses of India and Ceylon, with plate, by Otto Stapf. Cultivation of Citronella Grass in Java, and on Lemon Grass in the Malay Peninsula. *The Queensland Agricultural Journal*, November, 1906. *U. S. Department of Agriculture, Conditions affecting Legume Inoculation*, by Karl F. Kellerman and T. R. Robinson.

TRADE MEMORANDUM.

Mr. J. WORT, who has been with the firm of Messrs. B. S. Williams & Son, of Holloway, for over 24 years, has entered the service of Messrs. Dickson & Robinson, seedsmen, Manchester, and will represent this firm in the south of England.

THE COUNTRY-GARDEN.

THERE is more scope for individual character in the country-garden than there is in the majority of town or suburban gardens, for those in the country, as a rule, are more irregular in shape, and, more often than not, their outside settings may be taken into account, as they add materially to their character and beauty. To these things the country-gardener is often blind, or, at any rate, indifferent, so that he takes no advantage of them. They are, however, considerations that count for much in the beauty of the whole.

How shall we secure individual character in the country-garden? First and foremost, I think, by launching out a little from the narrow limits that now rule. Let us set ourselves to study the capacities for beauty, the true decorative value of a wider range of hardy plants, perennial, biennial, and even annual. It is the fault of a number of our English gardens that they are too much alike, and when I say that, I mean that we see the same varieties of flowers in each. This detracts immeasurably from the general interest. Let us say, for argument's sake, that the plants seen everywhere have been proved eminently desirable. This is to be taken for granted. Let us grow them by all means, but not so exclusively that we have no space to devote to some of the less familiar forms of plant-life. It is the rarer and more unfamiliar that go far to make the interesting garden, if, at the same time, they have other qualities that make them good garden subjects.

We must remember that it is easier and far more inexpensive now than it was even ten years ago to grow these rarer plants, because the seeds are more readily obtainable, and it is quite certain that gardening in England received a wonderful impetus when packets quite inexpensive (but not cheap, because the number of the seeds is so small) became purchasable. This small number of seeds answers the purpose a great deal better than a larger and more expensive packet containing enough seed to stock the entire garden.

It will be my object in these short papers to try and bring before the notice of my readers plants that, really and truly, add both interest and beauty to our gardens, and to say why these plants deserve their distinctive places. It may be distinctiveness, or beauty of form, or a quaintness of habit, or growth, that give them a unique value. It may be the particular time that a plant flowers that makes it invaluable, or the long season over which it is in blossom. It may even be the size of the flower that shall fit it for some especial position. These are matters of vital importance in achieving a beautiful garden, but nine out of ten English gardeners do not trouble their heads over such matters (!); and I am sure I am right in saying that the reason for this is that they have not realised that such considerations are needful. They are needful. The time has come when our gardens may become not only realised dreams of loveliness but, at the same time, the flower-garden, to a great extent, of almost every country in the world except those within the tropics, while we may even have representatives from these.

Let me speak to-day of foliage plants only. No border should ever be planted without due consideration to the value that certain types of foliage will give to the general character. The clean-cut, stern foliage of the swordblade type is one that yields great distinction of form amid a mass of a more indefinite and less marked character. Are we utilising such a subject as *Phormium tenax* as we might? To my mind this is a better border subject than the Yucca. It springs broadly out of the soil, with a bold, upstanding effect. It is evergreen, and it is hardy, and grows into massive clumps. In fact, it has so much character that it should be in such a position that this is duly emphasised. Other plants should not be established too near

it, nor should anything high enough to hide any part of it be planted in front of it. Let it stand out for all that it is worth—and it is worth a good deal.

Take, again, the case of the Pampas grass (*Cortaderia*). Are we making all that is to be made of so grandly decorative a subject? March or April is the season to transplant this. Can we remove it to a more effective position than the one it now occupies? It must have the maximum of sunshine and a good open place, but let it be a beautiful picturesque feature in the garden. Last autumn I saw some grand clumps in an old garden, hidden away and half choked with tall perennials in an out-of-the-way corner. Such a subject as this is surely worthy of the utmost prominence. Its beauty and gracefulness should be made to tell as a keynote, as it were. Out-of-the-way corners are not for plants such as these. *Practical Gardener*.

ORCHID NOTES AND GLEANINGS.

CYPRIPEDIUM ACTÆUS LANGLEYENSE.

THIS beautiful hybrid *Cypripedium*, fig. 10, is not new, for it was granted an Award of Merit by the Orchid Committee of the Royal Horticultural Society as long ago as January 27, 1900, but it was shown in such fine condition by Major Holford at the meeting of the R.H.S. on December 15 that the committee raised the award to that of a First Class Certificate. As indicated by one of the varietal names, the plant was raised at Langley by Messrs. James Veitch and Sons, Ltd. The parents were *C. insigne* Sanderæ × *C. Leea* giganteum. As will be seen on reference to our figure, the dorsal sepal is exceptionally handsome, the white ground being sparsely spotted with purple and blotched at the base with green. The petals and lip are yellow, the former with a slight brown line and some dark-coloured hairs at the base.

CYPRIPEDIUM ACTÆUS, TRACEY'S VARIETY.

AMONG a very interesting series of varieties of *C. Actæus* flowering with Mr. H. A. Tracey, Amyand Park Road, Twickenham, this very pretty and novel variety is prominent by its good shape and attractive colouring. The lower half of the dorsal sepal is pale greenish yellow, with distinct blotchings of light purplish chocolate, which change to rose-coloured spots on the lower part of the upper white portion. The petals are broad, yellow-tinged, and spotted with purple. The labellum, which is a very attractive feature, is reddish rose with the upper margin and the interior bright yellow. The staminode is yellow, with an orange centre. It was obtained from a cross between *C. insigne* Sanderæ and *C. Leea* Masreelianum. Another pretty form of the same class, but lighter in colour, and several of the commoner green and white forms are also in bloom. *Cypripedium insigne* Amesianum, a worthy variety of the *C. insigne*, Harefield Hall class, but with a bright colouring of *C. insigne* Chantinii, is flowering with Mr. H. A. Tracey, Orchid Nurseries, Twickenham, out of a freshly-imported batch. The flowers are large and of fine substance, the lower half of the dorsal sepal yellowish, with large chocolate-purple blotches, the upper half white with a few rose-purple spots. The broad petals and lip are yellow, the former spotted with chocolate-purple and the latter tinged with the same colour. It is a strong grower, and well worthy of a place among choice forms of *C. insigne*.

"LINDENIA."

AFTER a considerable interval between the publication of Part 8 of this illustrated work on Orchids, Parts 9, 10, 11, and 12, necessary to complete vol. xvii., have come to hand together, and complete the work on the original

lines, if the intention to discontinue it in its present form recently expressed is adhered to. The issue of the present four parts give coloured plates and descriptions of the following plants:—

Cattleya Hardyana var. *majestica*.—A very finely-coloured variety near to *C. H. Laversmensis*, for which Lord Rothschild received a First-Class Certificate at the Royal Horticultural Society, July 24, 1894. Sepals and petals rich purplish-rose, mottled and veined with white; lip claret-crimson with gold-coloured disc.

Cattleya Pannemackeriana (*Hardyana* × *Rex*).—A very distinct hybrid. Sepals and petals pale buff-yellow, tinged with rose; lip

Cypripedium Lucienianum superbum.—A very showy flower, with the large white dorsal sepal freckled with rose and bearing dark-purple dotted lines. Face of the lip tinged with purple; the whitish petals tinged with rose and spotted with chocolate colour.

Cypripedium Chantino-Lawrenceanum.—A large-flowered hybrid; a variety of *C. Umlaufianum*.

Cypripedium Vialianum (*Lathamianum* × *Drurii*).—Upper sepal white with a red-brown base; the rest of the flower yellow tinged with brown.

Cypripedium Théodore Bullier (*tonsum* × *villosum*).—A distinct, light-coloured hybrid with strong evidence of *C. tonsum*. Raised by

FIG. 10.—CYPRIPEDIUM ACTÆUS LANGLEYENSE. Photo. by J. Gregory.

ruby-crimson, with the fine veining in the throat seen in *C. Rex*.

Cattleya Triana Brandneriana.—A noble white flower with rich purple front and orange disc to the lip.

Cattleya Triana Fascinator.—The sepals, and very broad petals, pale lilac with the white ground showing through; lip rosy-crimson with orange disc.

Cypripedium glaucophyllum.—The ally of *C. Chamberlainianum*, illustrated in the *Gardeners' Chronicle* supp., Dec. 12, 1903.

Cypripedium insigne cinnamomeum.—A singular yellow variety with reddish markings.

Cypripedium Lathamianum princeps.—Upper sepal white, with feathered rose lines; petals and lip yellow, marked with red-brown.

Monsieur Opoix in the gardens of the Luxembourg.

Odontoglossum chromaticum.—A supposed natural hybrid between *O. Hallii* and *O. polyxanthum*. Segments narrow and nearly equal. Sepals and petals pale yellow, spotted with red-brown. Lip broad, white with a yellow crest, bearing reddish lines.

Odontoglossum crispum Gairceanum.—The beautifully-coloured variety for which Norman C. Cookson, Esq., Oakwood, Wylam, received a First-Class Certificate at the Royal Horticultural Society, May 26, 1903. One of the most remarkable and finely-blotched varieties of the favourite species.

Oncidium incurvum album.—The white variety of the graceful rosy-lilac coloured species.

VEGETABLES.

AUTUMN AND WINTER CABBAGES.

In the spring I wrote of the value of early Cabbages at that season (see *Gardeners' Chronicle*, April 21, p. 242), and referred to later kinds for furnishing a whole year's supply. The following remarks concern the value of these vegetables at this season.

Autumn and winter Cabbages are not largely grown, owing, doubtless, to other members of the genus *Brassica* being available at these seasons, but the smaller kinds of hardy Cabbage are valuable at a time when there is none too many good vegetables to be had. No note on this subject would be complete without reference to the Colewort type, but these do not call for any lengthy remarks, for their culture is well known; but I would add they are most valuable to fill in the interval between the late summer and early autumn supplies. For later use I prefer the winter Cabbage to the hardy green Colewort, using the Rosette for the earlier supply. There are not many distinct types of winter cabbages, but quite enough exist for the purpose: these I will enumerate, and also their season. A large grower of these vegetables once informed me that any variety could be grown for winter if sown for the purpose. Such, however, is not the case, for even the true autumn Cabbage—the Rosette Colewort—bursts and decays in bad weather, whereas the winter kind, with a firm, close heart, often of a Drum-head shape, is proof against the changes of our variable climate. I do not advise the growing of large varieties of Cabbages, as the larger kinds are not the best, they have too much stalk. For some seasons I grew Sutton's Favourite for a late autumn supply. This is a very dwarf variety, with a solid heart, and, sown in May or June, will furnish good "heads" well into December. The best autumn and winter Cabbages are those having a compact growth and with few waste leaves. I prefer a dwarf variety. Some years ago, in order to obtain a winter Cabbage with the best possible flavour and having a certain degree of hardness in its constitution, I raised a variety from the Rosette Colewort crossed with Christmas Drumhead, and this has the edible quality of the first-named cabbage, but is a much firmer and better winter variety. This I called the St. Martin, and it is an excellent early winter variety, somewhat flatter in shape than the Rosette, but not unlike it in quality and growth. Another excellent late autumn Cabbage for use at this season—indeed, it may be called a mid-winter variety—is St. John's Day, a very good Cabbage to follow the Colewort. Sown in May or June, according to the locality, it will be found a reliable vegetable. It furnishes serviceable "heads" at a season of the year when "greens" are difficult to procure, and these are not coarse in flavour, indeed, they are little inferior to the spring Cabbage, and, in my opinion, are much superior to the coarse Savoy Cabbage so much grown. The next of the late winter kinds to note is the Christmas Drumhead, and, as its name implies, it is in season at Christmas, but, being of a flat, drumhead shape, very firm, and with leaves folding closely over each other, with scarcely any waste, this variety is as good in February and March as at Christmas, and it is not readily injured by severe weather. Sown in the late spring or early summer months, it will give a supply till the early spring Cabbages are ready, and the quality is excellent. This is also a dwarf grower, and does not occupy much space, though it is larger than the earlier ones named above.

The above four varieties will give a full supply at the seasons named, and as their growth is made late in the summer and early autumn, the plants should have an open position and be planted in well-cultivated soil that has been deeply dug, for deep culture is quite as important as the affording of manure. Allow ample room in the seed-bed to secure strong plants, and should the ground not be available for their transplanting when they are ready, it is advisable to replant the seedlings a few inches apart, and to transplant them finally in their permanent quarters. This method will ensure strong, sturdy plants and furnish good returns in a short time. *Geo Wythes.*

PLANT NOTES.

MEDEOLA ASPARAGOIDES.

In this climber gardeners and florists possess an easily grown plant which is capable, under good management, of affording much material for cutting from the month of February till April.

The seed should be sown in boxes or pans in the spring, the seedlings being shifted, as soon as the tubers have formed, into small 60's or large thumb pots to the number of three or four, in which they should be encouraged to make roots. In the month of July a bed in a house should be prepared by deeply digging in some short, decayed stable dung. The young plants should be set out in lines at 2 feet apart, and the young growths to the number of two or three should be secured to strings running upwards from the ground level to the roof. Any shoots coming from below and all side shoots should be removed after this is done, in order to secure fine, regular main growths. At the first the chief factors are abundant warmth and moisture, but so soon as the plants have reached the height of 3 feet, syringing must be only moderately carried out, otherwise the leaves will become of a yellow tint.

The tubers, when allowed to remain undisturbed, afford capital growths for a series of years, and these increase in vigour year by year. These strong growths are much in demand by the commercial florists, for the reason that they admit of division, and thinner growths are likewise sufficiently abundant. The older the plants the smaller the degree of warmth required, and the greater the amount of ventilation necessary, conditions of cultivation which make for longer durability of the growths when cut from the plants; the "leaves" come likewise smaller, which is an addition to their attractiveness, and the growths remain for a longer period in a perfectly healthy condition. The earliest period at which newly-planted *Medeola* growths may be cut is the month of September; still, they are not then quite perfect. The succeeding growths attain a height of 2 to 2½ yards. An entire glasshouse planted with *Medeola* cultivated in the above manner is a pretty sight.

SALVIA SPLENDENS COMPACTA.

This new variety of a showy species, for a long time cultivated for early winter-flowering, is well worthy of the attention of gardeners. The flowers are of a bright scarlet colour, as in the type form, and the plant reaches a height of only 1½ feet. If planted out, when danger from frost is passed, in the month of May, the plant will begin to blossom in June and continue in good flower till November. *F. M.*

THE ROSARY.

ROSE MEMORANDA FOR JANUARY.

SEE that all newly-planted trees are well mulched with manure and made secure in the ground. If the soil is in a sticky condition and not fit for planting to be properly accomplished, the plants will be better "heeled in" until February or March. All vacant ground should be trenched and well manured in readiness for later planting, and the Roses will succeed better in land that has been worked in advance. Established Roses in pots will now be growing freely, and the temperature of the house may now be increased to 55° in the day time and a few degrees less at night. If former instructions are followed, the plants should now be breaking evenly and strongly, and a little ventilation can be given a few hours daily on the south or west side of the house on favourable occasions. On bright mornings a light syringing overhead will tend to keep aphids in check and cleanse the foliage. The Rose is impatient of a dry atmosphere; cool and rather humid atmospheric conditions are the most desirable, although excess of moisture thus early in the season must be guarded against. A great enemy to the Rose is mildew, and precautions must be taken to prevent it. The best antidote for this fungus is "sulphur-vivum" and soft soap, 1 lb. of each ingredient to be well mixed together in a warm solution, and when the hot-water pipes are quite warm, paint them thickly all over with the fungicide; the fumes will spread in the house, and touch every particle

of the foliage, and one application is usually enough, but if the foliage is very badly affected a second is desirable. This is by far the best remedy against mildew. Ordinary flowers of sulphur dusted on the foliage only partially effects a cure, whereas the former thoroughly eradicates the fungus without disfiguring the foliage. Roses that were potted during the autumn and which are already pruned, can be placed in the cool end of the house in a temperature of about 50°, and kept rather dry at the roots for a time, giving them an occasional sprinkling of tepid water overhead and about the paths, on bright mornings. Allow very little ventilation for the first week or two of forcing, and gradually increase the temperature to 60° with the increase of sun power and as the season advances. Grafting Roses on established stocks will now be in full operation. Place the stocks under frames in a glass-house, and allow a temperature of from 60° to 65°, until the union is effected. Open the lights for a few hours each morning after the first week or so, to expel excessive moisture. The earliest batch of grafted plants should be ready for taking from frames early in February, when they should be stood in the house near to the glass. After January, dormant grafting should cease, and herbaceous grafting take its place, soft wood for the purpose being taken from the earliest forced plants; later, the growing tops from the pushing grafts will furnish material. Besides dormant-grafting in autumn and herbaceous grafting in the spring, it is surprising in how many different ways the propagation of the Rose can be effected. Cuttings 9 inches in length obtained from matured wood, and inserted in October, or cuttings taken from forced plants during the spring and "struck" on hot beds, and, later in the season, from well-ripened, stubby shoots planted in sandy loam under cloches or hand lights, and, lastly, late summer and autumn budding outside, are some of the best methods of propagating the Rose. *J. D. G.*

NOTICES OF BOOKS.

SUCCULENTE EUPHORBIE. By Alwin Berger, Curator of Sir Thomas Hanbury's Botanical Garden at La Mortola. Published by Eugen Ulmer, Stuttgart.

WE have in this work of 130 pages octavo, written in German, one of a series of illustrated handbooks which deal with succulents, or as they are called in that language *Feltflanzen*, viz., Aloes, Agaves, Mesembryanthems, Crassulas, Cacti, and plants of allied genera. As the author states in his preface to the present work, these various handbooks will be issued in quick succession, each complete in itself. They are intended, in the first place, for the use of those who are engaged in the cultivation of succulents and Cacti in general, and as a guide to the identification of the numerous species, and for affording all that is worth knowing about them in a condensed form.

The information afforded is such that it will enable anyone, with a little trouble, to distinguish and identify any unknown forms. No such work has appeared since Haworth's *Synopsis plantarum succulentarum*, in 1812; and the abundant literature concerning the different genera is greatly scattered through numerous works, thus making a study of the plants without the use of a large library an impossibility. In the century that has elapsed since Haworth's time, the number of genera and species made known has, in many cases, increased tenfold.

The author was induced to publish these various handbooks on succulents by Herr. Harry Franck, of Frankfurt-on-the-Main, a most active member of the German Cactus Society, and who died before the first volume was published. His name is commemorated in *Euphorbia Franckiana*, a species not hitherto described; and his son furnished the photographs for the illustrations of the present work. It will be remarked how large is the number of new species mentioned, many of them old introductions, but which have become lost to cultivation, as so often happens to garden-plants. The descriptions of the plants, with the object of economising space, is not given in Latin, but in the German language; and they

are made as brief as possible, and foreign expressions are avoided.

Herr. Berger acknowledges the assistance and support that he has received from Sir Thomas Hanbury, the owner of La. Mortola, in his studies of succulents, and thanks also Professor A. Engler, Director of the Botanical Gardens, Berlin, for his valuable communications, notices, and materials; Professor Dr. G. Schweinfurth for descriptive matter and drawings of Arabian and Abyssinian Euphorbias; Dr. R. Marloth, of Cape Town; Mr. N. E. Brown, and Mr. Cooper, of Kew; Mr. Irwin Lynch, of Cambridge, and others.

It is only a fractional portion of the great order Euphorbiaceæ that is described in the work, and this fractional part consists of plants that are mostly natives of the warm, arid regions of Africa and Asia; their fleshy tissue eminently fitting them as reservoirs of moisture, enabling them to exist during the seasons of drought, and their prickles and poisonous juices—extremely virulent in certain species—affording protection to the plants from browsing animals. The descriptions of the flowers and fruits will mostly interest the botanist; as likewise the mode of growth, the differences of which enabled the author to form various groups, which he designates by the letters A, B, C, D, and E. He then takes each group separately, describing some of the more remarkable species as regards leaves, stems, branches, spines, flowers, capsules, seeds, and giving the natural habitats. The student is thus afforded a ready means of identifying an unknown plant. The illustrations, mostly reproduced from photographs, are very good, but we should have been glad to have seen more of them.

In the short chapter on the cultivation of succulents, and the propagation of those species which, for certain reasons, do not bear fertile seeds, and must be raised from cuttings taken at the beginning of the summer, the observation is made that the old-fashioned mode of heating a glasshouse, in which the tender species are to be wintered, by means of a flue is better for the plants than hot-water heating. The winter temperature for Euphorbias, Stapelias, and some species of Cactus, needs to be only moderate, but the atmosphere must be dry. In many glasshouses, heated by water, the temperature may be kept low, but the air is moist, and it is this moist state of the air that is the cause of so many losses among tender succulents, even under the care of the cleverest gardeners. There are among the non-succulent species of Euphorbia, several which are well known in gardens, viz., *E. pulcherrima* (*Poinsettia pulcherrima* Graham); *E. fulgens* (*E. Jacquiniflora* Hooker); and *E. splendens* Bojer ex Hook, in *Bot. Mag.*, t. 2902, and the variety of it named *parviflora*. A considerable list of authorities is appended, also a full index of the contents of the volume.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

MEGACARPÆA ARMENA.—This is a little-known plant in gardens, but by reason of its peculiar-looking flowers and stately habit, it might find employment as a solitary example in the middle of a bed of other flowering plants, or on the turf in one or more specimens together. The flowers endure for a day or two, but there is a constant succession of them in May and June, and in the latter month new ones develop. The plant is hairy in all parts, and reaches a height of one yard or less accordingly as the soil is rich or otherwise and the climate is favourable. The colouring of the blossoms is pale blue and green, whilst the edge of the corolla is tinged with yellow, and the two upper segments are decorated with two violet-coloured stripes which descend into the throat. A hard shell encloses the seed, which must be removed with a knife before the seed is committed to the soil. The plant is quite hardy, and develops a rosette of large lanceolate leaves, from out of which the head of flowers shoots upwards. Can any reader of the *Gardeners' Chronicle* afford particulars as to the country of origin, and if the plant is known under another name? The figure given together with the note in *Die Gartenwelt* seems to point to the plant belonging to the natural order of Boragaceæ. F. M. [*Megacarpæa* should be a crucifer.—Ed.]

NEPHROLEPIS EXALTATA.—In the instructive article contributed in the *Gardeners' Chronicle* for December 29 by Mr. Druery, I observe a reference to some abnormal fronds that I sent to him more than ten years ago. The member of a local horticultural society, from whom I obtained them, retained the only fertile frond for his own use and gave me those that were barren. I regretted this at the time, as probably had the fertile frond been sent to Mr. Druery that gentleman would have been successful in rearing some young Ferns and watching their behaviour afterwards. The spores from the fertile frond germinated, but as the young Ferns appeared to degenerate my friend's gardener threw them away, although he was an experienced Fern-grower. If I could have secured them, they would have been grown on, but the break-up and removal of my friend's establishment prevented my securing them or the parent plant that had produced the abnormal fronds, although under Mr. Druery's advice I strenuously endeavoured to do so. I grew on some companion plants which were given to me at the time in the hope that one of them might prove to be the rarity, as after the abnormal fronds had been cut it was difficult to distinguish it from the others, but no "mutation" has occurred, and therefore I conclude that the first recorded sport of *Nephrolepis exaltata* was lost after the abnormal crested fronds were sent to Mr. Druery. W. Roupell, *Harvey Lodge, Roupell Park, S.W.*

CARBOLINEUM AS PROTECTION AGAINST INSECTS AND FUNGUS ON FRUIT TREES.—The *Gartenflora*, for December 15, 1906, publishes an article on this important subject, by the Director of the Royal Biological Institute at Dahlem, in which he is more inclined to attribute harm than good to its use on fruit trees, and his views are supported by those cultivators who have used this oil either with or without mixing with other ingredients, such as lime, soap, Bordeaux mixture, &c. The basis of carbolineum is coal tar, obtained in the process of making lighting gas, of which it is one of the by-products. After being distilled from the coal in the retorts, it is again heated and distilled at various temperatures (four usually), each giving a different kind, and the process is similar with the tar or pitch obtained from wood. In Germany there are about 80 carbolineum manufactories, and the various preparations on the market amount to 200 to 300. These preparations in their action on vegetation are different, and but little definite is known about their effects, only that these are mostly injurious, whether applied in winter or summer. F. M.

PHASANTS AND PLANTS.—In no case have I heard of pheasants attacking Gunneras. I have, however, heard of rats doing so, by taking the tender young growth. Yellow Crocuses are especial favourites of pheasants and other birds, and I know several places where no Yellow Crocuses can be kept on account of the pheasants, although there are many thousands of whites, blues, purples, and stripes. The pheasants destroy the bulbs as well as the flowers of the Yellow Crocuses, and it is apparently hopeless to plant these in places exposed to their attacks. S. Arnott, *Sunnymead, Dumfries, Scotland.*

RESURRECTION OF "LINDENIA."—I think that it should be good news to all lovers of portraits of beautiful flowers in general, and to Orchid-growers in particular, to hear that the publication by Mr. Linden, of Brussels, of the above-named beautifully illustrated work which was believed to be dead (as no part had been published since February, 1903), has been resumed by the appearance of a quadruple part, embracing Nos. 9, 10, 11 and 12, of Volume xvii., on December 6. It is also announced in the December issue of the *Revue de l'Horticulture Belge* that the first part of Volume xviii. of the work will be published on January 15, 1907. W. E. Gumbelton. [The plants illustrated in these parts are described on p. 12.—Ed.]

A "CHRISTMAS" ROSE.—I am sending you a Rose that I picked on Christmas morning from a standard tree growing in one of our borders. This is a cold part of the country, and we are over 600 feet above sea level. W. H. Collett, *The Gardens, Huntsham Court, Bampton, N. Devon.* December 27, 1906. [Several Roses were in flower at Ealing on that date, but we suspect that the weather on Boxing Day made the specimens the "last of the Roses."—Ed.]

THE WINTERS OF THE "GOOD OLD TIMES."—That quaint old chronicler, Samuel Pepys, for whom nothing was too small or too great to record, gave us a weather note for January 21, 1660-1: "It is strange what weather we have had all this winter; no cold at all, but the ways are dusty, and the flies fly up and down, and the rose-bushes are full of leaves; such a time of the year as was never known in this world before here. This day many more of the Fifth Monarchy men were hanged." The characteristic concluding sentence is decidedly gruesome. A. C. B.

THE WATER SUPPLY IN PLANT HOUSES.—After the fall of snow or hail the water in the receptacles becomes so intensely cold as to be injurious when applied to the roots of plants growing in a warm atmosphere. The temperature of the water applied to stove plants should exceed by 5° that of the atmosphere of the house. Crotons and Codiaums especially are most susceptible to paralysis of the roots by the application of a cold supply, and the effect is frequently noticeable at this season of the year, by the shedding of their leaves. B. Cromwell.

SOCIETIES.

SCOTTISH HORTICULTURAL ASSOCIATION.

AFTER the reading of Mr. Wallace's paper, published in full in our columns by the courtesy of the author, Mr. David Thomson, the President of the association made some comments, which are here reproduced with a few omissions.

Gardening in America is a very much more simple matter than it is here. This statement may appear strange to some of you, but it is a fact, and the reason is not far to seek. In America there are but two seasons—summer and winter. When the winter closes, it is done with, and summer sets in. There are no intermittent frosts and warmth such as we have here. The temperature is not at 60° one day and at 30° the next, and when vegetation bursts into growth it receives no check as it does here, and hence the reason that many plants that succeed out of doors in America, although their winters are more severe, will not exist in this country. Spring frosts, which work such havoc in our northern isle, are unknown there.

Well, gentlemen, I suppose you all know something about the Yankee. America is a big country, and its people all like big things. They all like big boots and big clothes, and especially big hats. They like big button-holes and talk big. They have big hotels, big lakes, and high mountains. When they have an earthquake, it is a big one. When they have a railway smash, it is a big one, and their explosions are awful. Their drinks are peculiar. They have "corps revivers" and "cock tails." It seems that they have big nurseries, and grow some things in big quantities and get big prices for their flowers; but it is quite evident from this paper that they have to depend on Scotsmen for their horticultural products.

Mr. Wallace has mentioned many names in his paper. They certainly all sound Scotch, and seem to have gone from all parts of Scotland, and I am sure we are all pleased to know that they are doing so well, and upholding the great name of Scottish gardeners, and I hope that all of them will join the Scottish Horticultural Association, and send their 2s. 6d. in advance. They have plenty of money out there, and amongst other big things they have, they have some big millionaires—men who count their dollars by millions.

That it is a good thing for a country to have a score or so of men with about a hundred millions amongst them is very doubtful, I think. Only fancy, if that money were more equally divided amongst a greater number of the working people of a country, how much more good it would do, and how much more happiness it would create. Mr. Wallace has not told us if there is a millionaire horticulturist in America, so that we might approach him for a donation to our funds, or that we might persuade him to leave some of his dollars to build a home for horticulture in this city. Some of the names he mentions may be familiar to some of you, and I have no doubt they are. There is one familiar to all horticulturists in this country, and that is the name of Douglas, whose

e must for ever be connected with horticulture in this country, and whose untimely death you deplored.

Douglas was the means of introducing many of our best and most useful ornamental trees and shrubs. This raises a thought in my mind. Supposing we were to take away all the hardy plants and those that have been introduced into this country—which must be called exotics, I suppose—what would be left? What would the land be without foreign trees and shrubs? Nearly a barren wilderness. True, we should have the Scotch Fir or Mountain Pine, we should have no Larch, no Spruce, no Douglas Fir, no Austrian and no Corsican Pine. We should have the Ash and the Oak, but no more or Plane tree. I am afraid I am lingering from the subject, and must return to the United States.

There are one or two men that occur to me who have not been mentioned in the paper who have helped to forward horticulture in the Eastern Hemisphere, and one of them an old member of this association—George MacLure, known to you all, is now the leading landscape gardener in New York; and Robert Low, my old assistant of my own, is now one of the young men in the seed warehouse of Messrs. H. J. Persson, who is now placing the expert knowledge acquired under my tuition at the disposal of the gardeners of the United States. The Mr. Elliot was whose forefathers were "klers," I do not know; but am glad to hear he was found out to be a "richt."

Mr. Scott, who holds a similar position in the New York Florists' Club that I hold in the British Horticultural Association—at least, in my lifetime—I think I remember at Newbattle, would here like to shake hands with him across the sea, or send him a wireless message to show him great joy as a Brother President, or ask him to send us a paper for our next syllabus, for which I will send him one in return, and will send Johnstone out to give a night with Burns.

Wallace's advice to young gardeners who are of going out to America will be of interest to our younger members. It is that "A man wants only health, hands, a good character and good spade to work his way in this country. Well, a young gardener wants all that in this country, and something more, and that is the desire to improve them; and he says that "So long as the present system prevails in Britain, gardeners will meet much better encouragement there than in this country." What he means, I cannot quite follow, but he cautions the young men of this country by telling us that matters there are very different as they are here, and that there is often a bundance of applicants for any vacant position. In his closing remarks he pays a tribute of respect to Scotch gardeners when he says that "as a class, Scotch gardeners head the list for all-round satisfaction, and I, in conclusion, at this, the last opportunity I shall have of pressing you as your President this year, press the hope that the young and rising generation of the Scotch gardeners will continue to better themselves and to educate themselves in a way that they will long continue to hold the high position they have acquired all over the world. It has been the object of this association to forward their interests, and I trust that it will continue to be so for many years to come."

THE HORTICULTURAL OF IRELAND

DECEMBER 17.—The annual general meeting of the above society was held in the Leinster Hall, Dublin, on this date, F. W. Esq., presiding. The annual report was read, for it showed a financial loss of £100. The society's spring show, which of late has been taken the form of a two days' floral exhibition, is the only exhibition of the year that has been financially successful, and this is to be re-arranged for 1907 some time in April. It is a great regret that negotiations with both the National Rose and the National Sweet Pea societies for holding exhibitions in Dublin during the coming summer have been abortive. Of the retiring members of the council, F. W. Moore, C. M. Doyne, G. M. P. Goodbody, W. J. Mitchison, and E. J. in were re-elected. The other vacant places on the council were filled by Messrs. R. W. F. Gunn, and Professor Houston.

NATIONAL CARNATION AND PICOTEE (SOUTHERN SECTION).

DECEMBER 14.—The annual general meeting of this society was held on the above date, and was well attended by the members. Mr. Martin R. Smith, president of the society, occupied the chair. The report showed a very satisfactory year's work, and it was decided to increase the value of the prizes, and also offer additional ones in many classes in the forthcoming exhibition. The annual exhibition was appointed to be held on Wednesday, July 24th, 1907, in the R.H.S. Hall, Vincent Square, Westminster. It was decided to invite trade exhibitors. The new departure, made at the last show, of giving equal recognition to undressed as to dressed flowers gave much satisfaction, and will be adopted on all future occasions. Considering the vicissitudes of the season, the show of 1906 gave every satisfaction, and very keen competition obtained in some of the classes.

The report for 1905, of which 1,000 copies were distributed, contains much useful information, and gives a list of the winning flowers, by which means the best varieties for show purposes are made known to exhibitors. The cost of printing and distributing the report entailed a somewhat increased cost in the working of the society. The balance-sheet showed receipts from all sources of £287 6s. 6d.; the expenditure amounted to £189 11s. 3d., leaving a credit balance of £97 15s. 3d. The amount disbursed in prize money during the year was £88 3s.; the cost of printing and working expenses generally was £101 8s. 3d.

ROYAL METEOROLOGICAL.

DECEMBER 19.—The monthly meeting of this society was held on the above date at the Institution of Civil Engineers, Great George Street, Westminster, Mr. Richard Bentley, F.S.A., President, in the chair.

Admiral J. P. Maclear read a paper on "The Guildford storm of August 2, 1906." This storm shows some very curious and interesting features, in the remarkable violence of the wind, rain and hail, within a small area, and the suddenness with which it burst. There was an area of thunderstorms over the whole of the south of England on the evening of that day. The most violent storm, however, burst over Grayshott on Hindhead at 8.30, and pursued a narrow track through Godalming and Guildford to Ripley, 5 miles north-east of Guildford. The wind was of hurricane force, and blew down an immense number of trees and caused other damage and also the loss of two lives. The rain, accompanied by large hailstones, was very heavy, as much as 1.17 inch falling at Grayshott in 15 minutes. There was a magnificent display of lightning, the flashes being incessant and darting from cloud to cloud.

Mr. R. Inwards read a paper on "The metric system in meteorology." The author did not discuss the general question of the advantages of the metric system over that in use by Britain and her colonies and United States of America, but confined his remarks to the advisability of adopting some uniform system by all the meteorological observers upon the globe.

Obituary.

EDOUARD PEETERS, *Chef de Cultures* in the Royal Gardens, Laeken, Brussels, died recently, at the age of 40 years.

ENQUIRIES AND REPLIES.

GAS-LIME AS A REMEDY FOR EEL-WORMS.—In answer to B.A.'s question in last week's issue, gas-lime has been proved to be a good preventive against Eel-worm attack to the Tomato plant. About ½ cwt. (28 lbs.) is sufficient for a cart-load of soil. It should be well mixed with the soil so as to distribute it evenly through the whole mass, giving the heap two or three turnings before using, so as to expose the centre of the heap to the influence of the atmosphere to get rid of the poisonous properties of the gas-lime before it comes in contact with the young

roots. The soil will be ready for use in March if the lime is added at once. If the soil has previously grown Tomatoes, Cucumbers, or Melons, be careful to pick out every bit of root and burn it, because the Eel-worms will remain alive in every portion that is left in the soil. Decomposing plants and roots are frequently to be found teeming with both worms and eggs. Some recent experiments have shown that Strawson's "Vaporite" applied at the rate of 2 lbs. to the pole of land is an excellent preventive against Eel-worm. The gas from the Vaporite will kill all the Eel-worms that are hatched out. J. J. Willis, Harpenden.

AMPELOPSIS VEITCHII: H. R. This plant is most easily raised from layers, but it can also be readily propagated from seeds, cuttings, and "eyes."

ANNUALS BENEATH ROSE BUSHES: J. B. We know of no such work as you mention, but you will find much useful information on this subject in our issues for March 31, 1906, p. 199; April 7, 1906, p. 215; April 21, 1906, p. 247; and May 5, 1906, p. 279, in our Weekly Calendar on Work in the Flower Garden.

ASPARAGUS, &c.: H. R. We cannot trace such a name as Asparagus Sieberianus, not even as a synonym. Send us a portion of the plant for identification.

AUCUBAS NOT FLOWERING: Lenden. The frequent failure of female plants of Aucuba to produce fruits is generally due to the absence of male plants, and consequent non-fertilisation of the flowers. In your case the failure is due to the plants not having produced flowers. We should not subject the plants to heat, or too great a supply of water, but leave them to flower naturally, which they are pretty sure to do in course of time.

BOOKS: T. E. M. *The Book of Market Gardening*, by R. Lewis Castle, obtainable from our publishing department, at the price of 2s. 9d., post free.

ETHERISATION OF RHUBARB, &c.: H. C. Mr. W. Stuart, of the Vermont Experimenting Station, U.S.A., conducted the following experiments with Rhubarb. The roots were dug in the autumn and allowed to freeze. In December they were gradually thawed in a cool cellar. The roots were etherised for 48 hours in an airtight box, using 10 cubic centimetres of ether per cubic foot of space. The plants etherised were of earlier and more vigorous growth, and yielded increased weight of product when compared with specimens left untreated. See also a note on Mr. Jannoch's method of forcing plants by this system in our issue for October 6, 1906, p. 237.

FERN PROTHALLI: P. T. You should bake the soil on the boiler in the stove-hole before you sow the spores. This will sterilize it and kill all fungi present and seeds of weeds. The fern spores must not be germinated in too close an atmosphere, although plenty of moisture is necessary for their germination. When they have reached the prothallial stage, the glass slips covering the pans may be tilted to allow of ventilation, before removing them altogether.

GARDEN SOIL: R. T. So far as we are able to examine the soil received, there appears to be nothing in it that would be likely to cause any injury to the roots of Seakale plants. It is singularly free from humus, and is likely to be deficient in available plant-food. As a Fellow of the Royal Horticultural Society, you should send a sample to Dr. J. A. Voelcker, M.A., 22, Tudor Street, E.C., the society's analyst, who in return for a small fee will analyse it, and thus determine whether or not it contains injurious salts.

GRUBS ATTACKING ROOTS OF THE LILY OF THE VALLEY: R. C. The grubs are those of the common swift moth, "Hepialis lupulinus." These larvae often attack the roots of herbaceous plants. The only practical course we can advise

is to remove the plants to another site, as far as you possibly can from the position they at present occupy. In doing this you must destroy all the grubs that you can find. We would also advise that the infected plot be given a heavy dressing of gas lime.

HOT WATER WASTING THROUGH EXPANSION PIPE: Boiler. We notice in the sketch plan that you have sent us that there is only one valve in one of the two principal main flow-pipes running in rectangular directions, and that properly enough this is fixed in the main having a very sharp rise up a hill side and from which one house is heated on the right and three houses on the left. But one throttle valve should also be fixed between the bend rising from the principal main flow and the connecting branch flow-pipe in every case; otherwise we fail to see how a satisfactory circulation of hot water can be obtained and regulated throughout your heating system. Your supply cistern is rightly fixed in a house occupying the highest level (12 feet) above the heating apparatus and more than 100 feet distant therefrom, thus showing that your 20 foot high expansion pipe obviously contains water for 12 feet above the boiler level, with the result that when the water attains to the boiling point it rushes up the 8 foot empty space of expansion pipe. Bad circulation in the 80 foot principal main-flow, and the branch flows therefrom, into three separate houses, contribute not a little to this waste of hot water through the expansion pipe. As advised at p. 436, we should recommend you to add a 6 foot length of gas tubing to your expansion pipe, making the connection with a S shaped bend with a view to minimising, if not entirely preventing, the waste of hot water in this direction. A stay should be put to the additional length of tubing to prevent its being displaced by the effect of high winds. We are afraid it would be too risky at this time of year to advise you to endeavour to give a little more rise to your level main flow-pipe, but it might, perhaps, be done in warm weather by careful and judicious leverage through the medium of a crowbar passed through a chain or stout rope taken round the pipe and formed into a loop on top, commencing as a matter of course, at the end of the main farthest from the boiler. It will be wise to defer trying this experiment until the summer, when artificial heat can be dispensed with for a short time at least.

INCORUSTATED BOILER: T. C. This is caused through the use of water containing much lime. If your boiler is empty, you might, by removing the pad, chip off the incrustation with an old chisel. We presume that your boiler is saddle-shaped, and if this is the case, we may say that in our experience of such boilers, from which the incrustation has been removed—or indeed whether it has been removed or not—the wrought iron plate gives way within a short period of time afterwards; it becomes burned through. However, as prevention is better than cure, we recommend the following simple remedy to soften water before use if due to temporary hardness—i.e., matter which is deposited on the waer boiling. Put a little lime, such as is used by builders, in the water in a tank, and allow it to settle, when the lime (calcium oxide) will combine with the carbon, which at present is keeping the calcium or magnesium carbonate in solution as bicarbonate. Both the calcium and magnesium carbonate will be then precipitated. This solution will in time soften and reduce the incrustation on the side of boiler to a harmless powdery state. One or two pounds of dust lime tied up in a stout piece of cloth and placed in the supply cistern would serve to soften about 100 gallons of hard water, renewing the supply of lime at intervals corresponding with every 100 gallons of water put into the cistern. The "Carlton Boiler Fluid," manufactured by Walter Voss & Co., Limited, Carlton Works, Glengall Road, Millwall, London, E., is an excellent preparation for the purpose indicated above. Anti-Calcareia is another preparation for softening hard water, but it is expensive.

MARKET CHRYSANTHEMUMS: H. R. We should increase rather than reduce the list of sorts you name. They are all good ones, and the great advantage of growing a number of sorts is, that it gives a little more variation in the time of flowering, and certain varieties succeed best

in certain localities. Taking the November flowering white varieties, we find that some growers do not succeed with Western King, while others have it in splendid condition. "Star" is more suitable for growing as a pot-plant, and would hardly pay for cultivation merely for supplying blooms for cutting. We may add here, that although known in the market as "Star," this variety is properly named "Ivory." Niveum might be put into the December list, for it will even last into January. Among red flowers for November, Exmouth Crimson may be added, also Matthew Hodgson, and for December, Violet Lady Beaumont should be given a place. We might add many other useful sorts.

MISTLETO: A. C. Horton. You must not only place the seeds in the crevices of the bark, but in addition it will be necessary to protect them from birds, which otherwise would probably discover them all and remove them. Another method is to cut a notch in the bark on the under surface of a branch, and place the seed in this in such a position that the embryo of the seed will be directed towards the trunk of the tree. In your district (Kent) it should not be difficult to establish this parasite on your aged Apple trees.

MUSHROOM PESTS: L. P. G. Your Mushrooms are attacked apparently by two very different pests. The larger ones, which jump when touched, are no doubt from what you say one of the "springtails," or Poduridæ; the smaller ones are not the young of the others, but belong to the family of mites. They are identical with the "bulb mite," Rhizoglyphus echinopus, or belong to a very nearly allied species. A number of these were at work on the gills, and also two colonies in the stems, in which they had formed large holes; they are probably more injurious to the crop than the "springtails." As to the best way of destroying these creatures, it is very difficult to know what to recommend without injuring the mushroom bed. Thoroughly spraying it with a solution of paraffin emulsion, or certain other insecticides, would no doubt kill the pests, but it is uncertain what effect such a proceeding would have on the bed. The mites are still more difficult to deal with, as insecticides cannot be made to reach them inside the Mushrooms. Probably the best thing to do would be to entirely remake the bed, taking away all the old soil, &c., and scalding all brickwork, boards, &c., which the old bed has been in contact with. Thanks for 2s., which has been placed in the R.G.O.F. collecting box.

MYOSOTIS ALPESTRIS "VICTORIA": H. R. This variety is an improvement on the type. In habit it is more compact, and the flowers are larger.

NAMES OF FLOWERS, FRUITS AND PLANTS.—We are anxious to oblige correspondents as far as we consistently can, but they must bear in mind that it is no part of our duty to our subscribers to name either flowers or fruits. Such work entails considerable outlay, both of time and money, and cannot be allowed to encroach upon time required for the conduct of the paper. Correspondents should never send more than six plants or fruits at one time: they should be very careful to pack and label them properly, to give every information as to the county the fruits are grown in, and to send ripe, or nearly ripe, specimens which show the character of the variety. By neglecting these precautions correspondents add greatly to our labour, and run the risk of delay and incorrect determinations. *Correspondents not answered in this issue are requested to be so good as to consult the following numbers.* PLANTS: K. I. Y. 1, Margil; 2, Blenheim Pippin; 3, Harvey's Reinette; 4, Dean's Codlin; 5, King of the Pippins.—E. B. Whiting Pippin.—PLANTS: W. R. P. 1, Acalypha macrophylla; 2, A. macrostachys (syn. A. masaiica of gardens); 3, A. Wilkesiana var. marginata.—C. E. Frank. Bulbophyllum Pechei.—Northumbrian. Epidendrum cochleatum, one of the oldest Epiphytal Orchids in gardens.—A. B. Eschynanthus splendens.—J. D. Den-drobium infundibulum, of no special value.—Henry. 1, Cotoneaster microphylla; 2, Escallonia macrantha; 3, Cratægus pyracantha; 4, Escallonia rubra var. punctata; 5, Euonymus europæus; 6, Berberis stenophylla.

PAINTING WOODWORK OF GLASS-HOUSES: East Herts. The wood being in the condition you have described it would be well to apply a good "primer" before painting with the best white-

lead paint. Any local painter will mix you the "primer." Or you might try the new "Lubrose" paint, which is obtainable from Mr. C. T. Druery, 11, Shaa Road, Acton, W.

PAYMENT DURING HOLIDAY ON CHRISTMAS DAY: H. We think that the men were entitled to payment if they were engaged and paid by the week. You had better consult a solicitor. In any case, the withholding of payment in the circumstances you describe appears to us as harsh. Are you members of the British Gardeners' Association?

POINSETTIA SPORT: G. C. We have seen similar light-coloured forms, and they are usually the result of defective culture.

POTATO TUBERS: B. L. The injury is of a mechanical nature, caused by some substance present in the soil. Such blackening and abrasion of the skin is often caused by the use of town manure containing ashes.

RHODODENDRONS AS HEDGE PLANTS, &c.: H. B. H. M. S. We do not remember to have ever seen the Rhododendron used as an ordinary hedge-plant. There are so many other subjects better adapted for the purpose. If Rhododendrons were clipped yearly, all, or nearly all, the flower-bearing shoots would be cut away. But if your object is simply to make a dividing line and to allow the plants to spread practically as they like, then the Rhododendrons would answer. Respecting specimen plants, these should, if possible, be obtained on their own roots, and encouraged to form a good foundation in the early stages of development. Assuming that you start with shapely plants, it will be an easy matter to train them into handsome bushes provided the soil contains no lime, but is cool, well-drained, and in a position exposed to sunshine. Beyond removing weakly shoots and keeping the centre of the plants free, little or no pruning is required. If you want to raise young plants from bushes already in your possession, you ought to layer a number of shoots at about the latter part of August or during September. Some of the layers may be severed from the parent plants in 12 months after layering, and if they attain a height of 10 inches or more without showing signs of producing side-shoots they should—if bush plants are required—be cut back, or the terminal bud taken out with the finger and thumb. The plants require all the sunlight possible, in order that the wood may become properly ripened. Standards are formed by running up strong shoots until the desired height is reached, all side-growths being cut away, so that the stems may become straight and clean. When the requisite height is reached they are allowed to produce side-shoots, and in some cases the point is removed to induce the formation of such shoots. Rhododendrons being surface-rooting shrubs, a mulch of leaf-mould or other suitable material in times of drought, and soakings of water once each week are of inestimable benefit. All seed-vessels should be removed immediately after the flowering period, at which time a good watering will greatly assist the plants to make vigorous growth.

RUNNER BEAN "FIREFLY": G. C. This was exhibited last autumn at one of the Royal Horticultural Society meetings, by Messrs. Sutton & Sons, Reading.

SEED CLEANING: C. S. & Co. The pods appear to be those of a Medicago allied to M. falcata.

SOLANUM CAPSICASTRUM: H. R. This plant may be readily raised from seed, but it is usual to propagate from cuttings, selecting the freest fruiting plants from which to take the cuttings.

STRAWBERRIES: H. R. The plants can be layered straight into their fruiting-pots, and this is a practice recommended by many growers of this fruit, but we prefer the use of small pots at the start, as the soil is likely to become sour in the larger pots before they are filled with roots.

COMMUNICATIONS RECEIVED.—B. Cromwell—T. W. Birkinshaw—J. H.—F. W., New Jersey (Your request for application form has been forwarded to the secretary of the British Gardeners' Association)—F. M.—B. NAMING PLANTS.

THE nomenclature of plants is, as all who have to deal with the subject recognise, in an unsatisfactory condition, and, whilst it causes experts unnecessary trouble and inconvenience, it gives occasion to outsiders to complain vehemently, or to indulge more or less mild satire. Linnæus was the first in modern, or comparatively modern, times to endeavour to set matters straight. To him we owe the binominal nomenclature; to him we are indebted for the first reasonable code in the *Philosophia Botanica*. Of course, the vast advances that have been made since his time have rendered some additions and modifications desirable, but these are nearly all we conform to the principles laid down by the great Swede, the better for all. There is a general agreement to adopt the year 1753 as the starting point of binominal nomenclature. In that year the first edition of the *Species Plantarum* was published. It is not necessary here to discuss all the reasons for selecting that date, sufficient to say it is in every way the most convenient. After Linnæus, Auguste Pyramus Candolle introduced amendments and modifications; Lindley did the same. Alphonse de Candolle, the son of Auguste, drew up the famous "Lois" and submitted them for ratification and adoption to a Congress of botanists, held in Paris in 1867. These have been followed, with comparatively few exceptions, up to the present time. Some of the American botanists, breaking away from the practice of their revered leader, Asa Gray, have set up rules of their own. Dr. Otto

Kunze has done the same thing and created synonyms by the thousand. It would be tiresome, and indeed unnecessary, here to discuss these proposed amendments. Suffice it to say that at a Congress of Botanists, held in Vienna in 1905, and attended by hundreds of botanists of all civilised nations, the "Lois" of Alphonse de Candolle were submitted, paragraph by paragraph, to keen scrutiny. Some were retained, others modified, many added. The results, edited by Mr. John Briquet, which we take to be morally binding on all botanists, are published in French, and in German, and in English under the English title of "International Rules of Botanical Nomenclature." They may be had from Messrs. Williams and Norgate, or any firm of foreign booksellers.

It is quite unnecessary for us to discuss these rules in their entirety. Some of them affect horticulturists, and to these alone we desire to call attention.

The code, if we may so call it, is divided into (1) "articles," in which the principles are embodied and which are, of course, the most important; (2) "rules," which are based on the foregoing principles; and (3) "recommendations," which allow greater latitude to individual botanists.

We now set forth those articles, rules, and recommendations which are of special interest to horticulturists. Separated from their context, they appear disjointed, but it is not necessary here to allude to those paragraphs which concern descriptive botanists only. We have here and there made our own comments in brackets.

Art. 10.—Every individual plant belongs to a *species*, every species to a *genus*, every genus to a *family* [in this country family and order have been used synonymously, but this will no longer be the case], every family to an *order* [thus corresponding to what we have been accustomed to call cohort], every order to a *class*, every class to a *division*.

Art. 11.—In many species we distinguish *varieties* and *forms*, and in some cultivated species, modifications are still more numerous, in many genera sections, in many families tribes.

Art. 12.— . . . If circumstances require us to distinguish a greater number of intermediate groups, it is easy by putting the syllable "sub" before the name of a group to form sub-divisions of that group. In this way sub-family (subfamilia) designates a group between a family and a tribe; sub-tribe (subtribus) a group between a family and a genus. The arrangement of subordinate groups may thus be carried, for wild plants only, to twenty-one degrees, of which we give the English names in the following order:—

Vegetable kingdom.	
Division.	
Sub-division.	
Class.	
Sub-class.	
Order.	
Sub-order.	
Family.	
Sub-family.	
Tribe.	
Sub-tribe.	
Genus.	
Sub-genus.	
Section.	
Sub-section.	
Species.	
Sub-species.	
Variety.	
Sub-variety.	
Form.	
Individual.	

If this list of groups is insufficient it can be augmented by the intercalation of supplementary groups so long as these do not introduce confusion or error. (Ex.—*Series* and *sub-series* are groups which can be intercalated between sub-section and species.)

Art. 13.—The definition of each of these names of groups varies up to a certain point according to individual opinion and the state of science, but their relative order, sanctioned by custom, must not be altered. No classification is admissible which contains such alterations. Examples of inadmissible alterations are a form divided into varieties, a species containing genera, a genus containing families or tribes. [Schedule framers should carefully note this article. At present they are frequent transgressors.]

Art. 16.—The designation of a group by one or several names is not for the purpose of describing the characters or the history of the group, but that we may be understood when we wish to speak [or write] of it.

Art. 21 and 22.—Families (familie) are designated by the name of one of their genera or ancient generic names with the ending *aceæ*—thus Rosaceæ from Rosa, &c.

There are a few exceptions (Art. 22) sanctioned by long usage—Palmeæ (better Palmaceæ), Gramineæ, Cruciferae, Leguminosæ, Guttiferae, Umbelliferae, Labiatae, Compositae. [It would have been better to have followed Lindley, and by various means to have made all groups of equal family-rank end in *aceæ*.]

Art. 23 (condensed).—Names of sub-families . . . end in *oideæ*, names of tribes end in *eæ*, and of sub-tribes in *ina*.

Recommendation XII.—When it is required to express a sub-generic or sectional name, together with the name of the genus and the name of the species, the name of the section is put between the others in a parenthesis, e.g., *Astragalus* (*Cycloglottis*) *contortuplicatus*.

Recommendation X.—Specific names begin with a small letter, except those which are taken from names of persons (substantives or adjectives), or those which are taken from generic names (substantives or adjectives). Examples: *Ficus indica*, *Circaea lutetiana*, *Brassica Napus*, *Lythrum Hyssopifolia*, *Aster novi belgii*, *Malva Tournefortiana*, *Phyteuma Halleri*.

Recommendation XI.—When a specific name is taken from the name of a man, it is formed in the following way:—

(a) When the name ends in a vowel the letter *i* is added (thus Glaziovii from Glaziov; Bureaui from Bureau), except when the names end in *a*, when *e* is added (thus Balansæ from Balansa). [Confusion would arise in some cases, where it would not be possible to distinguish between a male and a female writer; thus Trianae might apply equally well to a male or a female.]

(b) When the name ends in a consonant, the letters *ii* are added (thus Magnusii from Magnus, Ramondii from Ramond), except when the words end in *er*, when *i* is added, thus Kernerii. [Why this exception should be made is not clear.]

(c) Syllables which are not modified by these endings retain their original spelling even in the case of the consonants *k* or *w*, or groupings of vowels, which are not used in classic Latin. Letters, foreign to the Latin of botanists, should be transcribed, and diacritic signs suppressed. The German *ä*, *ö*, *ü* become *æ*, *œ*, *ue*; the French *é*, *è*, and *ê* become in general *e*.

(d) When specific names, taken from the name of a person, have an adjectival form, a similar plan is adopted. (*Geranium Robertianum*, *Carex Halleriana*, *Ranunculus Boreauanus*, &c.)

Recommendation XII.—The same applies to the names of women. These are written in the feminine when they have a substantival form. (Example: *Cypripedium Hookeræ*, *Rosa Beatrix*, &c.)

Recommendation XIII.—In the formation of specific names composed of two separate roots and taken from Latin or Greek, the vowel placed between the two roots becomes a connecting vowel—in Latin *i*, in Greek *o*; thus we write *menthifolia*, *salviifolia*, not *menthæfolia*, *salviæfolia*. When the second root begins with a vowel and euphony demands it, the connecting vowel is eliminated (e.g., *Calliantha*, *lepidantha*). The connecting *x* is legitimate only when etymology demands [it] (e.g., *Caricæformis* from *Carica* may be retained along with *Cariciformis* from *Carex*).

Art. 30.—Forms and half-breeds among cultivated plants should receive fancy names in common language as different as possible from the Latin names of the species or varieties. When they can be traced back to a species or sub-species or a botanical variety this is indicated by a succession of names. (Example: *Pelargonium zonale*, Mrs. Pollock.)

Art. 31.—Hybrids between species of the same genus, or presumably so, are designated by a formula, and whenever it seems useful or necessary by a name. The formula consists of the names or specific epithets of the two parents in alphabetical order and connected by the sign $\times$. When the hybrid is of known experimental origin the formula may be made more precise by the addition of the signs.

Art. 32.—Intergeneric hybrids (between species of different genera) or presumably such, are also designated by a formula, and when it seems useful or necessary by a name. The hybrid is associated with the one of the two genera which precedes the other in alphabetical order. The name is preceded by the sign $\times$. (Example: $\times$ *Ammophila balsica* = *Ammophila arenaria* $\times$ *Calamagrostis epigeios*.) [In such a case the combination of the two generic names preceded by the sign of hybridity would seem preferable—thus $\times$ *Calamophila*—after the pattern of $\times$ *Philageria* or $\times$ *Urocharis*.]

Art. 35.—Communication of new names at a public meeting or the placing of names in collections or gardens open to the public do not constitute publication. [This renders invalid names given at an exhibition.]

Art. 36.—On and after January 1, 1908, the publication of names of new groups will be valid only when they are accompanied by a Latin diagnosis.

Art. 42.—When a manuscript name has been published and referred to its author, the name of the person who published it should be appended to the citation. The same rule should be followed for names of garden origin when they are cited as "Hort." (Example: *Capparis lasiantha*, R.Br., *ex*, or, *apud* D.C.; *Streptanthus heterophyllus*, Nuttall in Torrey and Gray; *Gesnera Donckelaarii* Hort., *ex*, or, *apud*, Hook, *Bot. Mag.*, tab. 5,070.

Recommendation XXXII.—Botanists should use in modern languages Latin scientific names, or those immediately derived from them, preferably to names of another kind or origin. They should avoid the use of the latter unless these are very clear and in common use.

Recommendation XXXIII.—Every friend of science should oppose the introduction into a modern language of names of plants which are not already there, unless they are derived from Latin botanical names by means of some slight alteration.

The rules now adopted will continue in force till the next Botanical Congress to be held in Brussels some years hence, when further modifications may be made if deemed necessary, and when the questions relating to the naming of cryptogamous and of fossil plants will be taken into consideration.

NEW OR NOTEWORTHY PLANTS.

PYCNOSTACHYS DAWEL.

N. E. BROWN (N. SP.).

THIS is a handsome new Labiate which has lately flowered in the T range at Kew Gardens. It was discovered in Uganda by Mr. A. Whyte, in 1898, and was afterwards collected by Mr. M. T. Dawe, who sent seeds of it to Kew, in 1905, from which the plants now in flower were raised. It is a stout herb, 4 to 6 feet high, with a loosely-branched pyramidal habit. The stems are square, puberulous, with opposite narrowly lanceolate leaves, 5 to 12 inches long, $\frac{1}{2}$ to $1\frac{1}{2}$ inches broad, tapering into a long, acute point at the apex, and narrowed into the petiole at the base, serrate on the margins. Each branch terminates in a spike, $1\frac{1}{2}$ to 5 inches long, and $1\frac{1}{2}$ inches in diameter, of cobalt-blue flowers. The spikes are very densely many-flowered, and their unopened flowers are

appear to be allied to *P. affinis*, Gürke, which I have not seen. The genus *Pycnostachys* may be distinguished from *Coleus* and *Plectranthus* by its needle-like calyx-teeth and denser spikes. N. E. Brown.

FOREIGN CORRESPONDENCE.

GERBERA JAMESONI.

IN the issue of the *Gardeners' Chronicle* for December 22 there is an article upon *Gerbera Jamesoni*. This handsome plant interests me very much, and I have cultivated it for three years. Last year I obtained good results, and so exhibited an important lot at the Chrysanthemum exhibition held in November in Paris. Your correspondent, Mr. Burt-Davy, of Pretoria, says that during the last three dry years it has been rather unusual to find *Gerbera* produce seed on either wild or cultivated plants, but that this year his plants are bearing more fertile

FIG. II.—*PRIMULA PALINURI*, NATIVE OF MOUNTAIN SHOWN AT FIG. 12: FLOWERS YELLOW. (From *Botanical Magazine*.)

more or less concealed by the incurving, narrowly lanceolate, acuminate bracts, which, as well as the long needle-like calyx-teeth, are ciliate with long, spreading hairs. The corolla is about $\frac{3}{4}$ -inch long, and the tube is very slender and straight at the basal half, then bent at a right-angle, dilated and compressed, with the margins of the mouth inrolled; the upper lip is equally 4-lobed, and of a darker blue than the rest of the corolla, with the two middle lobes very concave; the lower lip is compressed, boat-shaped, with the obtuse apex abruptly inflexed. The species would

seed, perhaps on account of the greater rainfall, or perhaps because the plants are older. I believe that both explanations are wrong. Here in my garden I gather as many seeds as I wish, and this year I shall be able to sell the seeds by the million. I have remarked that in moist and rainy weather the production of seeds is very much smaller than in dry and warm weather. But I have gathered, and gather every day, numerous seeds on very young plants. It is usual here, in the Riviera, to gather seeds upon plants seven or eight months old. I have now in my greenhouses thirteen plants from seeds sown on June 23, 1906, every one of which has a flower-bud, and one plant that has now one flower-bud, one open flower, 6 centimetres ($2\frac{1}{2}$ inches) in diameter, and one stem 15 centimetres (6 inches) in length. I hope to obtain seeds of this plant in two months' time. I may write you the result if it would be interesting. R. Adnet, La Roseraie, Cap d'Antibes, December 23, 1906.

* *Pycnostachys Dawel*, N. E. Brown. Herba 4-6 ped. alta, laxa ramosa. Rami tetragoni puberuli. Folia 12-30 cm. longa, 1-2.4 cm. lata, petiolata, anguste lanceolata utrinque longe angustata, acutissima, serrata, utrinque tenuiter puberula. Spicæ terminales, dense multifloræ, 8-12.5 cm. longæ, 3.5 cm. diam. Bractæa 9-11 mm. longæ, anguste spatulato-lanceolatæ, acuminatæ, incurvæ, longe ciliatæ. Calycis tubus parvus, glaber, inter dentes in lobulis minutas ciliolatas productus; dentes 6 (fructu usque ad 10) mm. longæ, aciculares, basi longe ciliatæ. Corolla corulea, tubus basi gracilis, superne abrupte compresso-inflatus et deflexus, labium superius equaliter 4-lobum; labium inferius compresso-naviculare, apice abrupte inflexum.

PLANT NOTES.

PRIMULA PALINURI.

THERE is a peculiar interest attaching to plants which are to all appearance destined to speedy extinction. One such plant is that mentioned in the following note. It is a native of the promontory of Palinuri, in Southern Italy, and is not found elsewhere. The dry, rocky character of the spot on which it grows is well shown in the accompanying reproduction from a photograph (fig. 12), kindly furnished by Mr. Sprenger, of Naples. It is curious to see how similar are (or appear to be) the conditions under which *P. Palinuri* grows in Italy, and *P. sinensis* near Ichang, in Central China, as narrated and figured in our columns by Dr. Henry and Mr. E. H. Wilson.

If unscrupulous botanists and traders lay themselves open occasionally to the charge of exterminating rarities, there is something to be said on the other side, for certain plants which grow in a single locality, and which are approaching extinction, are preserved by the cultivator. So it is with *Primula Palinuri*, which

during July. The East Indies is the home of two species—the white flowered *P. zeylanica* and *P. rosea*, a species which is now in season and deserves extended culture. It was introduced so far back as 1777, but whatever welcome it met with then it is now a comparatively rare plant. If stove heat can be given it, there are no insurmountable difficulties attending its culture. Care in watering is the chief essential, especially at this season. The bright rosy flowers are borne in long terminal spikes, and with care its flowering period can be prolonged for fully 10 weeks. While in flower the plants should be given a light, dry position, and the syringe must not be allowed near them. After flowering the plants should be kept "on the dry side" (but not absolutely dry) for four or five weeks. After this rest they should be lightly pruned and started into growth, using the syringe freely and the watering-pot but sparingly. When growth commences, the plants should be shaken out and re-potted in a compost of sound loam and leaf soil, with plenty of grit to keep it porous, pressing it firmly, and using well-crooked pots of moderate size—as a rule, 5-inch to 7-inch pots will

APPLE AND PEAR CULTURE
IN CO. CORK.

OUR Apple trees are principally pyramid-trained, and comprise over 50 varieties. The fruits last season were larger, better-coloured, and superior in every way to those of previous seasons.

The varieties Beauty of Bath and Lady Sudeley are the first to be harvested, being ready about the last week in August, and these are succeeded by Worcester Pearmain, Gravenstein, and Devonshire Quarrenden in September and early October. Cox's Pomona, which was ready for the dessert table at the latter end of October, was very finely coloured. These are closely followed by Maltster and Blenheim Pippin; this latter generally furnishes a long supply of dessert Apples. Among kitchen varieties Lord Grosvenor and Ecklinville Seedling are both admirable for use in August and September, after which period the varieties Warner's King (of which the heaviest fruits this year weighed 18 ounces), Tower of Glamis, and nicely-coloured specimens of The Queen afford both culinary and dessert fruits. Then Golden Noble, which has finished well this season (the heaviest fruits turned the scale at 12 ounces), and Stirling Castle suffice for culinary purposes until the end of November. Lady Henniker is an Apple which does remarkably well here, some of the fruits weighing as much as 12 ounces, and it is in season for culinary and dessert purposes in December and January. Lane's Prince Albert is an excellent Apple in season in November, along with another good Apple, Waltham Abbey Seedling. Tyler's Kernel promises to be a most useful variety. Roundway's Magnum Bonum, Charles Ross, and Peasgood's Nonsuch are all varieties which succeed well here.

Our culinary varieties for February are Bramley's Seedling and Newton Wonder. These are splendid croppers and the fruits are of first quality. Some fruits of Bramley's Seedling weighed 12 ounces. Northern Greening and Dutch Mignonne, with Sturmer Pippin and Allen's Everlasting, furnish a supply well into May.

The above is a summary of the principal, tried varieties. Numerous others, which have been planted here during the last two or three years, have not been sufficiently tested for me to pronounce an opinion upon.

DESSERT PEARS.

The following varieties are generally successful in this district:—Jargonelle, Beurré Giffard, and Williams' Bon Chretien (trees of which we have planted on S.W. and E. aspects) almost invariably furnish good crops, both on wall and on pyramid-trained trees. Marie Louise and Duchesse d'Angoulême furnish a good supply of fruits from mid-October well into November, in which month Beurré Diel is also in excellent condition. Another good medium-sized, well-flavoured, juicy Pear is Comte de Lamy. Doyenné du Comice, Doyenné Boussoch, and Pitmaston Duchess furnish well-coloured fruits of excellent flavour. The heaviest fruits of Doyenné du Comice this year weighed just over 12 ounces. These, with the inclusion of a few other kinds, such as Josephine de Malines, Passe Crassane, and Winter Nelis, carry the supply well on into the new year. Easter Beurré, I regret to say, is not equally successful here.

For stewing purposes we find nothing to surpass Catillac and Vicar of Winkfield. A wall in these gardens about 200 yards in length is entirely utilised for the culture of culinary varieties of Pears. C. Price, Mitchelstown Castle Gardens.

[Photo by Mr. Sprenger.]

FIG. 12.—NATIVE AND EXCLUSIVE HABITAT OF PRIMULA PALINURI, IN SOUTHERN ITALY.

may be found in botanic gardens, and is included in the *Kew Hand-list*. The figure of the leaf and flower here given are copied from the *Bot. Mag.*, t. 3414. The leaves are covered with a white meal, and the flowers are of a yellow colour.

PLUMBAGO ROSEA.

IN point of numbers the genus *Plumbago* is not noteworthy, but its distribution is remarkable. The blue *P. capensis*, from the Cape of Good Hope, is well known and variously grown in most gardens as a greenhouse shrub or as a pillar plant for summer bedding. *P. Larpentæ* hails from China. This is a hardy perennial; it has the slender habit of the genus, and bears heads of violet flowers. Siberia supplies an annual species having white flowers. *P. europæa* originated in that vast district vaguely termed "South Europe." It is a hardy herbaceous perennial, bearing in September heads of bluish flowers on 8 foot high branches. Mexico gives us a dwarf shrubby species, *P. pulchella*, requiring tropical treatment. The West Indies has its representative in *P. scandens*, a climbing species, known as Devil's Herb, or Toothwort. It bears loose spikes of white flowers

be ample. While growth is in progress *Plumbago rosea* requires a plentiful supply of water. During June, July, and August the plants may with advantage be transferred to a cool house, and during this period and onwards great discretion must be exercised in watering. Early in September bring the plants into the hot-house, and give occasional doses of weak manure water until the first flowers expand. The variety *coccinea* has somewhat larger and brighter flowers, and should receive the same culture as the type. Propagation may be effected by division in the spring, or half-ripe cuttings will root freely in moderate bottom heat. A. C. B.

PLANT PORTRAITS.

LOBELIA KATHLEEN MALLARD.—*Garten Flora*, December 1, tab. 1,567. A double-flowered variety of a deep blue colour.

ROSE QUEEN OF SPAIN.—*Garden*, December 22, 1906. H.T., raised by Messrs. Bide & Sons, Farnham. A cross between Antoine Rivière and some unknown variety. Form globular, conical in centre; outer petals yellowish, inner ones flesh-coloured.

RUBUS PLATYPHYLLUS.—*Revue Horticole*, December 18. A Caucasian species with long, Raspberry-like fruits, highly recommended for jam-making.

THE CEROPEGIAS IN CULTIVATION.

Mr. N. E. Brown's article, which appeared recently (p. 383, vol. xxxix.), upon the remarkable *Ceropegia hybrida* that originated in the Botanic Gardens at Leiden, having drawn attention to this genus, may I add a few words regarding the species at present in cultivation?

It goes far to prove the neglect in which these singular plants have fallen that *C. similis* has been grown in England for twenty years as *C. Thwaitesii* without the error having been detected. The true *C. Thwaitesii* is a far more decorative plant, judging from the figure in the *Botanical Magazine* (t. 4,758), published in the January number for 1854, and drawn from a plant flowered at Kew, raised from seed sent from Ceylon in 1851 by Mr. Thwaites himself. This plant is now apparently lost to cultivation, and should this note meet the eye of any cultivator in Ceylon possessing it or the two other Cey-

(Gold Coast), *C. Gardneri* (Ceylon), *C. gemmifera* (Togoland), *C. hybrida* × (see p. 383 ante), *C. lucida* (Himalayan regions), *C. Lugardiae* (Mozambique district), *C. Monteiroæ* (Delagoa Bay), *C. radicans* (S. Africa), *C. rupicola* (Arabia), *C. Sandersoni* (Natal), *C. similis* (Ceylon) (?), *C. Stapeliiformis* (S. Africa), *C. Woodii* (Natal).

With three exceptions, these are all in my collection. My friend, Mr. Medley-Wood, grows two or three new species in the Botanic Gardens at Durban, but they are apparently difficult or slow of propagation, for he has not yet been able to send them to us. Their introduction is much desired.

In addition to the above, the following species were recently cultivated at Kew, but appear to be now lost:—

C. Bowkeri (S. Africa), *C. Decaisneana* (India), *C. multiflora*, and its variety *latifolia* (S. Africa), *C. perforata* (New Guinea, this species was introduced by Messrs. Sander in 1899), *C.*

This is interesting, as disposing of the supposition that a *Ceropegia* had been found in the New World. *Walter Ledger, 5, Wilton Road, Wimbledon.*

COLONIAL CORRESPONDENCE.

KENNEDYA PROSTRATA.

I AM forwarding to you a photograph of a native plant, a variety of which was recently referred to in a paragraph in the *Gardeners' Chronicle* as a pillar plant. I do not know what characteristics the named variety may have, but the form of *Kennedya prostrata* found in West Australia is a finer plant than the same species in the S.E. of Australia, being larger in its various parts, with the flowers of a brighter scarlet. The plant shown in the photograph was growing on the spot eight years ago when the house was built, on ground that had been a "paddock" or park-like enclosure, with Banksias, Acacias, Nuytsias, and other native species scattered over it. As it grew at the foot of a verandah-post it was tied up as the new growth appeared during the winter. By the time the main branches had finished their growth, the top of the pillar had been reached, after which secondary branches were produced. The plant is always prostrate in a state of nature, but suffers no injury from being trained up in full exposure to light and air. The up-turned tips of the branches appear to indicate the degree of elevation of the growing point in its progress over the ground in its natural prostrate habit, and if that is the correct explanation, it is interesting as showing the retention of the upward curve, although the position of the branches in relation to the ground has been altered. *Alex. Morrison, 149, Brown Street, Perth, W.A.*

[The photograph would not reproduce well.—Ed.]

PRETORIA.

HEREWITH I send two photographs of Transvaal trees. No. 1 (see fig. 13) is a fine specimen of *Acacia caffra* in full flower, overshadowing a native kraal at the farm Barraan's-Poort, near Pretoria, taken on September 30, 1906. The flowers are creamy-white, and borne in spikes about 3 inches in length. This is the finest specimen I have seen; it is one of the most abundant species around Pretoria, but usually occurs in bush form, perhaps because all the trees have been cut out for fuel and are only allowed to sucker to a limited size before being again cut out.

No. 2 (see fig. 14) shows two specimens of *Dombeya rotundifolia* in full bloom on a kopje at The Willows, near Pretoria. It is one of our most common kopje trees, and in early spring (August and September) produces a dense mass of white blossom before any leaves appear, as is indicated in the photograph. Those readers of the *Gardeners' Chronicle* who may have visited South Africa with the British Association will probably remember having seen it. When in full flower it reminds one not a little of an overgrown Pear tree; the Dutch name for it is Drall-pyr.

We are enjoying the best spring rains known for many years, so that there is now little fear of bad crops. There will be a great scourge of locusts, but we hope that our locust-officers will succeed in destroying the insects to a great extent before they can reach the flying stage. The cool, cloudy weather favours the growth of weeds, and the soil is too wet to allow us to hoe them out. My garden is a mass of *Cosmos* seedlings from last year's crop; two years ago it was bare veldt! Pretoria is gay with *Roses* just now, but there will be no *Rose* show this year owing to the financial depression. The golden blossoms of the Silky Oaks (*Grevillea robusta*) are also quite conspicuous in our gardens. *Jos. Burtt-Davy, Pretoria, Transvaal, October 14, 1906.*

[Photo by J. Burtt-Davy.]

FIG. 13.—ACACIA CAFFRA GROWING WILD BESIDE NATIVE KRAAL, BARRAAN'S-POORT, NEAR PRETORIA, TRANSVAAL.

lonese species—*C. biflora* and *C. Walkeriae*—their introduction would be greatly appreciated.

There are about 160 species of *Ceropegias* known to science, all confined to the Old World. In Africa they extend from Abyssinia to the Cape, including the islands of Madagascar, Zanzibar, and the Canaries. In Asia, they grow from Arabia to India, Ceylon, Java, New Guinea to the Philippines, and through the Himalayan regions to China, where Mr. E. H. Wilson recently discovered two new species, but these are as yet only in the form of dried specimens at the Kew Herbarium.

In spite of the large number known, and after some years of correspondence on my part, I have only succeeded in tracing the following species as being in cultivation in Europe:—

C. africana (S. Africa), *C. Barklyi* (S. Africa), *C. calcarata* (Mozambique district), *C. Cummingiana* (Philippines), *C. debilis* (Nyassaland), *C. dichotoma* (Canaries), *C. elegans* (India), *C. fusca* (Las Palmas, Canaries), *C. fusiformis*

Rendallii (Transvaal), and *C. Sororia* (S. Africa).

If any of these are in English private gardens or elsewhere, I am sure they would be acceptable at Kew.

In conclusion, may I point out an error which has crept into the *Index Kewensis* with regard to a plant therein specifically named *Ceropegia nitida*? It was originally described under that name in the *Encyclopédie Méthodique* (1811), Poiret's supplement to the botanical section, vol. ii., p. 178, from the specimen in the Desfontaines herbarium. A correspondence with our Consul at St. Domingo, and with the Botanic Gardens at Paris and Florence, who possess portions of the herbarium Desfontaines, proved fruitless, and it was quite by chance that I alighted upon Decaisne's *Etude sur quelques genre et espèces de la famille des Asclépiadées* in the *Annales des Sciences Naturelles* (Mai-Juin, 1838), in which it is given as a synonym of *Marsdenia nitida*, there described.

ORCHID NOTES AND GLEANINGS.

CYPRIPEDIUM INSIGNE "CLARE DOW."

A FLOWER of this exceedingly pretty variety is sent me by W. Millie Dow, Esq., Kirkcaldy, who takes special interest in varieties of *C. insigne*. It flowered out of a small lot of the "montanum" importation, and, like others of that class, has the features of *C. nitens*, and its fine substance and effective colouring. The dorsal sepal, which is $2\frac{1}{2}$ inches high and nearly as much in width, is apple-green on the basal two-thirds and pure white above, with seven or eight irregularly-placed rows of large chocolate-purple blotches, the upper blotch on the three central rows being on the white ground. The petals, when extended, are nearly 6 inches from tip to tip, each being 1 inch wide; yellowish tinged and veined with purple, except the tips, the medium line being darkest, and some dark spots displayed on the lower half.

quently imported since, it has been always in very small quantities. J. O'B.

WHITE CATTLEYAS.

IN the last number of the *Journal de la Société Nationale d'Horticulture*, M. Maron relates his experiences. He crossed in 1902 a pure form of *Cattleya El Dorado alba*, having pure white segments, the throat of the lip alone being yellow with a pure white form of *Lælia Perrini alba*. When the crossed seedlings flowered the blooms were all rose-coloured!

M. Bert obtained a different result. He crossed a white *Cattleya Mossiæ* with a white variety having a yellow throat. The result was a plant bearing pure white flowers. It is to be desired that these crossed plants should be self-fertilised; the results would show which characters are "dominant" and which "recessive," and then if the Mendelian hypothesis be borne out it will be possible for breeders to obtain results with a measure of certainty now unobtainable.

not possible, has an unmistakable fondness for the fullest light and air that can be given it. A fully exposed and sunny position is the best, while ultimate success will depend not a little upon the depth and the character of the soil about the roots. A most important item is that of autumn-planting, and it is important inasmuch as the large majority of the stoloniferous or underground shoots are produced at that season, appearing above ground early in spring. Concurrently with these underground stems any new root fibres are produced, and these greatly assist the newly-planted subject. So far as soil is concerned, that of a rather light and sandy nature is much the best, but the plant also succeeds well in sandy loam, and even in soil of a peaty nature. Where the soil is very light, sandy and shallow, cow-manure should be added. In light soils the planting cannot be done too firmly. I have employed the turf beater, garden roller, and spade scores of times to firm the plants in their positions even after firm planting. Newly-made beds or edgings of the plant are purposely walked upon with the same object. When forming edgings of the plant in such soils the ground is prepared as for laying an edging of Box, the soil made firm by beating, and the small portions of the plant buried well up to the lowest leaves. Happily, the leathery texture of the leaves is proof against injury from either treading or beating, and these are no longer necessary when the plant becomes established. A perfectly-drained soil is very necessary for the plant, and an assured depth of at least 12 inches of good soil. In large gardens, where a heap of old potting soil exists, nothing more suitable could be chosen. The capacity of the plants to flower year after year depends largely upon the production of new shoots from below. When in good condition, these shoots are produced numerously, and a tuft, becoming crowded in time, would then deteriorate. The remedy is division and re-planting. And were this done more frequently the almost flowerless tufts of this beautiful spring-flowering plant that too often are seen in gardens would be less frequent. E. H. Jenkins.

NOTICES OF BOOKS.

LANDSCHAFTLICHE GARTENGESTALTUNG. By Camillo Karl Schneider, with 78 illustrations. Published by Carl Scholtze (W. Junghaus), Leipzig.

THIS, in addition to the author's previous works on garden-making and cognate subjects, has met with a favourable reception in Germany and Austria. The topics discussed, unlike those in earlier works, are confined within narrower boundaries, and consist of personal views with regard to the modelling and formation of gardens in landscape style in opposition to the architectural, geometrical, and combination of all three, as are frequently found at the present day in all parts of Europe.

The whole is arranged in such a manner that anyone with experience in the formation and improvement of gardens, whether layman or practical horticulturist, can readily understand it, and the illustrations with which the book is furnished are precisely such as will please those who may not share the views of the author. He is concerned chiefly with the present and the future, the past being touched upon only so far as its lessons explain that which is stated and what is demanded by his subject. He holds the belief that the professional man and the layman differ so widely about that which is carried out and as to what should be done in this field as to be unable to give a proper verdict, therefore there is the greater necessity for the gardening art to speak for itself.

In many art-circles, and in particular among architects, the belief has become general that the formation of a garden, from the artistic point of view, is an architect's business; in other words, that no such thing as the art of *landscape* gardening exists. This view of the subject is contested by

[Photo by J. Burtt-Davy.]

FIG. 14.—DOMBEYA ROTUNDIFOLIA IN FULL FLOWER ON A KOPJE, "THE WILLOWS," PRETORIA.

The lower sepals are of large size, pale green with spotted purple lines. Lip large, pale yellow, tinged with purple. Staminode broad, yellow.

MILTONIA ENDRESII.

THIS pretty little ally of *M. vexillaria* is again in flower in the collection of R. I. Measures, Esq., Cambridge Lodge, Camberwell (gr. Mr. Smith), where so many pretty and singular plants find a congenial home. Although *M. vexillaria* is quite a common plant in gardens, the Costa Rican, *M. Endresii*, is but rarely met with. The delicate sprays of flowers are shaped like those of *M. vexillaria* except in the panduriform outline of the lip. They are white, with a faint rose line at the basis of the sepals and petals, and with two blotches of light purple, one on each side of the bright yellow crest. Although first discovered by Warscewicz on the Cordillera of Veragua in 1849, it was not until Endres re-discovered it in 1873 that a few plants were got home alive, and, although fre-

THE ALPINE GARDEN.

GENTIANA ACAULIS.

THE stemless Gentian is one of the most prized of low-growing perennial flowering plants, and, as such, is worthy of more than ordinary consideration at the hands of the gardener. The lovely species does not succeed in all soils and localities, and I believe it is stated that in some places the plant will not flower at all. To any such statement as this the words "if allowed to shift for itself" would appear an almost necessary qualification. In some places the plant continues to grow and spread, but the flowering is extremely sparse, or even unknown. Such conditions obtain where the soil is either of an extremely dry and sandy nature, or in gardens with a heavy or retentive soil over a lias or clay sub-soil. This Gentian, whilst apparently disliking low situations where a free circulation of air is

the author with great zeal and knowledge, and the illustrations included in the book give strong support to his views. There are pictures from many noted parks and gardens, private and public, in Germany, Austria, France, Italy, and Bosnia, the water scenes being very charming, some being natural, others artificial, but even in the latter nature is very closely followed. We do not see in what essentials the methods advocated differ much from those which for a hundred years have been the fashion in the best places in our own country. In Germany and Austria, on the contrary, where *die Englische* style has not been adopted, stiffness and formality are the characteristics of the laying out, with their concomitants, close planting, and groups of trimmed shrubs, both deciduous and evergreen, lack of breadth in the treatment of the planting, and the effects of light and shade but little considered. F. M.

The Week's Work.

FRUITS UNDER GLASS.

By ALEXANDER KIRK, Gardener to J. THOMPSON PATON, Esq.,
Norwood, Allos, Clackmannanshire.

Vines which failed to ripen satisfactorily should be examined at their roots in the inside borders, and if any long, bare roots, having few or no fibres, are found, such roots must be pruned. The best time to root-prune the vine is about the end of September or the beginning of October. But it can be done now, and it is not advisable to postpone the operation for a whole year. Cut out a trench down the centre of the border as far as the drainage material, and remove all the soil in the border nearest the vines until almost the stem of the plant is reached. Tie the roots in bundles as the work proceeds. See that the drainage provided is in proper order. Any roots found growing among the drainage material must be removed, and, when the trench is filled in, be laid in nearer the surface. Furnish some fresh compost composed of good turfy loam chopped into pieces about 3 inches square. To every 3 tons of loam add 1 cwt. of coarse-grade Vine manure; if the loam is of poor quality or sandy, add a further ½ cwt. of fine-grade fertiliser, a liberal quantity of wood ashes and lime rubble, mixing the whole thoroughly together. A light loam will not require the addition of as much lime rubble as a heavy one. Place a single layer of turves grass-side downwards over the drainage, and fill the trench with the compost, spreading the roots carefully as the work proceeds as near to the surface as possible. Shorten any long, bare roots to within 2 feet of the main stem. Consolidate the soil, and when all is finished give a copious supply of water and cover with a mulching of manure. The outside border may be renewed in the same manner during September or October next.

Young vines planted in new borders during last spring or summer should, if strong of growth, be shortened back to the bottom of the roof rafters, but if weak they must be pruned harder, say, to within 2½ feet from the ground. Two or three years old vines must also have their leaders shortened, according to the strength of the rods, and their laterals pruned back to a single bud. A length of 2½ to 3 feet of last season's growth will be sufficient to leave. Examine the inside borders, and if they are found to be well filled with roots add another 18 inches to the width of the border, using similar compost to that recommended above.

Peaches and Nectarines.—When the weather is too severe for work outside cleanse and, if required, paint the structures containing these fruit trees. The walls should also receive a coating of lime-wash, to which some sulphur has been added. The trees themselves should be washed with soft soap or Gishurst compound by means of a soft brush, taking care not to draw the brush backwards against the buds. After this operation prune and tie the branches to the trellises. Examine the border, and remove any loose soil down to the roots. Afford a top-dressing of light loam mixed with lime rubble and fine-grade Vine manure. Give the border a copious watering if at all dry. If, as is often the case, young trees are growing too vigorously, they should be lifted and root-pruned, and some lime rubble added to the border.

Strawberries in pots should be examined, and plants with best crowns be selected, cleaned, and have their pots washed. Place the selected plants in a gentle heat, in pits, or in a vinery that is shortly to be heated for forcing purposes. Keep the plants near to the glass, and maintain a night temperature of 45° rising to 55° by day. Do not unduly hurry them into growth, and afford ventilation only when it is necessary.

Cucumbers in pots will require a night temperature of 70°. Do not overcharge the atmosphere of the pits in which they are growing with too much moisture. Increase the heat, and afford more moisture as the days lengthen. Pinch the points of the shoots as the plants develop. Make a fresh sowing in pots for a successional crop.

THE FLOWER GARDEN.

By A. C. BARTLETT, Gardener to Mrs. FORD, Pencarrow,
Cornwall.

Bedding Pelargoniums.—Owing to the unusually dry summer, it was difficult last autumn to get sufficient cuttings without despoiling the flower-beds, and it may be necessary to make up the required numbers with spring-rooted plants. Judgment must be exercised when cutting growths for furnishing cuttings for this purpose, because if the plants are cut back very severely, it will be a case of "robbing Peter to pay Paul," and nothing will be gained. Keep the knife sharp, so as to make a clean cut, and remove the lower leaves and stipules. Place five or six cuttings in a 48 size (5-inch) pot in preference to boxes. Place them in a warm house and do not water them more often than is absolutely necessary. When they have made roots, these plants should be potted off singly into 60's (3-inch pots). The stock should be frequently looked over, removing all decaying leaves with a downward jerk. It is surprising what a small quantity of water suffices at this season to keep these plants in good health, and they will withstand a low temperature better if kept somewhat dry.

Propagation of Yuccas.—Any stems which have been broken down by the recent snow-storm should be used for purposes of propagation. If not too large, the head may be cut off and, after tying up the leaves, pot it firmly and plunge in a warm hot-bed. By May or June it will be sufficiently rooted to plant out of doors. The stem from which the "head" was severed may be laid full length in the propagating frame, or be cut up into short pieces. In either case, the dormant buds will soon grow and form shoots, which when 3 or 4 inches long may be taken off and rooted in small pots, or be allowed to form roots before being removed. Field mice often prove very destructive to Yuccas during hard weather, so that it is well to watch for any signs of them. The mice usually burrow under the plants, and then, secure from observation, eat all the pithy portion of the stem, leaving simply the rind and skin. The sickly appearance of the leaves is the first sign of anything wrong. As they have a storehouse of food, trapping is of little use. I have usually found that waterings with quassia chips infusion, or a handful of soft soap and a quarter of a pint of petroleum well mixed in 3 gallons of water and poured down the holes will drive the rodents away, and do no harm to the Yuccas. The soil around the stems should be examined at intervals, and the dose repeated if there are any signs of their return.

Protection.—Examine the protective material around the more tender plants and shrubs. Bracken and straw will be found sodden and of little value as protective material. This may be entirely removed, and either replaced at once with a fresh supply or withheld until the weather hardens again. The thawing of snow has also weighted down the layer of leaves which was placed over the roots of many plants, keeping the soil cold. A few minutes' work with a fork will remedy this. For protecting tender evergreen shrubs, nothing is better than to surround the bush with deer wire-netting, leaving 6 inches or so of clear space. In the bottom place about 3 inches deep of leaves, which will keep all frost out of the soil, and on this round the lower parts of the shrub lightly place a handful of dry bracken. Then stick in the soil around the plant, a few large branches of hardy evergreen—*Rhododendron ponticum* for choice. This

will give ample protection, and allow sufficient air and light to penetrate and keep the shrub in good health.

PLANTS UNDER GLASS.

By J. G. WESTON, Gardener to H. J. KING, Esq.,
Eastwell Park, Kent.

The forcing-house.—Continue to introduce successional batches of plants into heat according to requirements, taking care not to subject them to excessive heat at the commencement. It is a good plan to put small batches into fruit-houses which are just being "started," and move them into a greater degree of heat as it becomes necessary. Azaleas of all kinds (especially the *A. mollis* × *sinensis* varieties) are indispensable, the varieties Anthony Koster, Mme. A. Koster, and Glory of Boskoop being extra good for forcing, though unnamed seedlings may be procured more cheaply, and are capable of giving a splendid return. *A. Daviesii*, having sweet-scented, white flowers, is a favourite, and there is no lack of beautiful varieties of *A. indica*. Lilacs, Acers, *Prunus triloba*, *Wistaria*, *Laburnums*, and *Staphylea colchica* will all respond to forcing at this season. Standards of these species are very useful for the conservatory, and for the arrangement of groups. Sufficient *Spiræas*, *Lily-of-the-Valley* crowns and bulbs may be brought into heat. Tulips, perhaps, are capable of bearing more forcing than most bulbs. Daffodils should be brought along very gradually, and all bulbs must be thoroughly well rooted before they are forced, or failures will result. *Polygonatum multiflorum* (Solomon's Seal) is a capital plant either for cutting, or arranged with brightly-coloured flowering plants. Home-grown clumps, as a rule, are most satisfactory for forcing; the same may be said of *Dicentra spectabilis*, the forcing of which, however, must be done very gradually.

Violets in frames.—Air should be admitted every day when the weather is suitable. Remove all decayed leaves from the plants, and stir the surface soil occasionally to keep it sweet. Very little water need be afforded at this season. Contrary to several growers who have written in the *Gardeners' Chronicle* recently, I have always found the variety *Princess of Wales* to be more satisfactory than *La France*. Of the double-flowered varieties, Mrs. J. J. Astor is very free in flowering, and of a distinct shade of colour. This, together with *Marie Louise* and the white *Comte de Brazza*, are the varieties chiefly relied on here. A newer variety named Mme. Bertha Barron is under trial, but I have not grown it long enough to speak definitely of its merits.

Souvenir de la Malmaison Carnations.—These can be best wintered in a light, well-ventilated house, the conditions of which should be pretty much the same as those for the winter-flowering varieties [see Calendar in last week's issue], but the atmosphere may be slightly cooler. If the disease or "rust" is noticed, the plants should be examined every week, and every piece picked off on its first appearance and burnt. This practice, though making the plants look rather shabby for the present, will eventually stamp out the disease. There are various preparations on the market for spraying the plants, but my experience is that the above method, if persevered with, will invariably give the best results. Fumigate regularly in all Carnation and other plant-houses, not waiting until greenfly or other insect pests have a strong hold on the plants, as Carnation leaves, once having suffered from the ravages of these pests, will always show the effects, thus spoiling the appearance of otherwise healthy plants.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir TREVOR LAWRENCE,
Bart., Burford, Surrey.

Heat and moisture.—If the weather is mild, only a moderate amount of fire-heat will be necessary to maintain the proper degree of heat, and very few dampings down should be done when the external atmosphere is moist. The paths and stages of the East Indian division should be well syringed in the morning as soon as the proper degree of warmth is reached; in the afternoon, when the fires have been re-started, the paths, &c., may again be sprinkled. In houses where the atmosphere dries more quickly, it may be necessary to again

damp down lightly during the evening. In the Cattleya and intermediate houses a moderate damping of the floors two or three times each week will suffice. Some Cattleya houses, however, may be sufficiently moist naturally, and it will be only necessary to give the usual applications of water to the roots of the plants. As regards the cool houses, they also should be damped down or not according to their construction and situation. Generally, they will need but little damping after the necessary waterings and the washing of the floors have been carried out. Should the atmospheric temperature be more than 40°, admit a moderate amount of fresh air to the plants in all the divisions, carefully considering whether the houses are in exposed positions or otherwise.

Blinds for use in cold weather and bright sunshine.—There may still be severe and boisterous weather to come. See that all the lattice-wood blinds are in thorough working order by having the pulleys, &c., well oiled, so that they may be easily rolled down, and it is advisable to attach strong cords to them in order to keep them from being blown over should strong winds prevail. The present is a suitable time to take down any of these blinds that need repairing, taking the opportunity to oil and repaint them before refixing them to the roof. Our method is to do one blind at a time, and in the event of very cold weather occurring during the process, to cover the roof with other material. Where the ordinary canvas blinds are used, the old ones should be examined and repaired, and if any new ones are required, proper measurements should be taken, and the material placed in the hands of those who may have to make them. Prepare a number of garden mats by tying in the ends strong and neatly; these will be useful during very cold weather, and if rolled along the eaves, or lower part of the roof, they will be of great assistance in maintaining the proper degree of heat without the use of excessive fire-heat.

PUBLIC PARKS AND GARDENS.

By W. W. PETTIGREW, Superintendent of the Parks and Open Spaces in the City of Cardiff.

The making of provision for the playing of games in parks.—Although nearly everyone nowadays recognises the importance of fresh air in the preservation and improvement of health, it is still quite impossible to get people to leave the vicinity of their dwellings and get out into the open, unless there is some ulterior motive for their doing so. In nearly every large town and city, parks and open spaces of some kind are provided wherein the residents may enjoy better and purer air than is to be found in the crowded thoroughfares and hemmed-in streets. People, however, will not visit these parks simply for the sake of getting a breath of fresh air, hence the authorities are realising more and more that, in addition to providing large parks and open spaces, it is their duty to do everything in their power to attract the people to them. Thus their parks are made as beautiful as possible with varied kinds of flowering trees, shrubs, herbaceous plants, and conservatories filled with plants, so as to interest those with gardening and æsthetic tastes. Music is provided at stated intervals during the year to attract those who are musically inclined; and, lastly, provision is made for the enjoyment of all kinds of games and sports suitable to the area and formation of the ground at their disposal. The provision for, and encouragement of, sport is a most important function of a parks department, appealing as it does to old and young alike, and to every class of the community. The greater the diversity of the games provided for, the greater will be the number of people attracted to the parks.

Football and cricket.—Every parks department ought to provide ample room for the playing of football in the winter and cricket in the summer, these being the most popular of all our national games. From the parks management standpoint, the advantage of these games is that they not only attract and find amusement for the actual players, but they bring out great numbers of interested spectators.

Hockey, baseball, and la crosse.—Next in importance come the games of hockey in the winter, and baseball in the summer, and as these are both very popular, every effort should

be made to find room for them. La crosse is a winter game, which is now played in this part of the country, and we have found it necessary to make provision for it also.

Games for the pleasure garden.—The foregoing are essentially games for the young, and should be confined to the recreation ground pure and simple. There are other games which are more for the amusement of older folks, which are better allocated to some part of the pleasure garden, such as tennis, bowling, croquet, and quoits. These are now very often provided as part of a park's attraction, and are invariably greatly appreciated by the general public. Archery is a sport which is being introduced in a few parks for the benefit of the ladies, but, owing to its special requirements as to site, &c., it can hardly become general.

Water sports.—Where a park possesses a large lake fed by a constant stream of fresh water, there are possibilities of providing boating, bathing, fishing, and model yachting, and in winter skating and curling can all be indulged in during periods of frost.

The question of "condition."—Although it has been commonly agreed that public bodies need not attempt to keep public recreation grounds in such a good condition for play as private clubs keep their grounds, I think every effort should be made to keep the ground in the best possible condition for the playing of the game for which it is intended. Hockey and football grounds and cricket pitches should be rolled and mown as often as they need it, while in the case of tennis courts, bowling and croquet greens, as much care and attention should be bestowed upon them as is given by private clubs to theirs. This policy gives the greatest satisfaction to players, and pays in the long run.

THE HARDY FRUIT GARDEN.

By J. MAYNE, Gardener to the Hon. MARK ROLLE, Bickton, East Devon.

Pruning orchard trees.—In the carrying out of outdoor work such as planting, pruning, &c., the weather must be the determining factor, as even one night's frost of 12° is sufficient to prevent the ground being properly worked, unless it be trenching for a new plantation. Even in such a case it is unwise to bury hard, frozen soil 2 to 3 feet deep, because such soil would naturally remain cold and wet for a long period. Should there be a period of frost, however, a few hours in the middle of the day may be utilised to push forward the thinning, as well as the pruning and cleansing of orchard trees, still much neglected in many parts of the country. Trees that have been given little or no attention in the matter of spraying will sure to be more or less covered with Lichen, especially the trunk and larger branches. Much of this can be removed with a flat piece of wood and a half-worn-out scrubbing brush, thus leaving less for the spraying that should follow pruning. It is not good practice to be very severe in the pruning of a much-neglected tree, it being better to extend the treatment to the second season, thus preventing the tree from suffering too great a check. Cut away the worst of those branches which intercross with each other, and endeavour to keep the centre of the tree open to the influences of sunshine and air. Where a saw has to be used, the cuts should be made smooth and clean with a chisel, and afterwards coated over with Stockholm tar, which will prevent decay during the healing of the wound. Burn up the spray-wood, and return the ashes to the soil, such ashes having an excellent fertilising effect upon every kind of fruit tree.

Planting.—After planting young trees on a Grass-plot, the Grass or turf should not be allowed to grow within a radius of 6 or 8 feet of the bole.

Bush fruits.—Some delay the pruning of Gooseberry bushes until late in spring, especially where birds are unusually numerous, but if left to themselves the birds will serve all the shoots alike, and there is, therefore, very little to be gained by postponing the work. Last season's shoots are capable of yielding the heaviest crops. Cut out the points of such of these as will be retained at about 20 inches from the point of origin, and prune back "close-home" all surplus shoots, and any that are likely to reach the ground when laden with fruit. Keep the main shoots about 6 inches apart, and the centre of the bush open, so that

the gathering of the berries may be the more conveniently carried out. Select a number of cuttings from the straightest shoots about 12 inches long, and cut out all the "eyes" except the uppermost three. These should be planted in nursery lines 6 inches asunder. Red Currants require to be spurred back to within two "eyes;" extension shoots may be left 8 inches long. Cuttings should be made and set out in the manner recommended for Gooseberries. Black Currants require different treatment. Merely cut away exhausted branches, encourage basal growths to take their place, and spurring back side-shoots where these are too numerous. Cuttings of Black Currants should not be trimmed, it being desirable that sucker growths should appear annually. Syringe Gooseberry and Red Currant bushes with a thin mixture of soot and lime, and wind black and white cotton among the branches to scare away birds.

THE KITCHEN GARDEN.

By WILLIAM HONESS, Gardener to C. COMBE, Esq., Cobham Park, Surrey.

Globe Artichokes and Celery.—If these crops have not already been supplied with a covering of long litter, this means of protection should be afforded without delay. A few of the outer leaves should first be removed from the Artichokes and a few sticks placed close up to the plants to hold them up, and to prevent the litter from bearing directly on them, which might cause the plants to decay should there be a long period of wet weather.

Lettuce growing in frames should be afforded plenty of air on bright, dry days, and all decaying leaves should be removed at intervals. The variety of cabbage Lettuce known as "All the Year Round" usually winters well in frames, and will often do so on a warm vine border out-of-doors, turning in and giving good returns in early spring. Where Bell glasses or the French cloches can be obtained, the variety *Petite Noire*, sown at intervals during September and October, will yield a good supply of the most tender Lettuce throughout December until the end of February. After the last few warm days in early autumn this variety requires no air admitted whatever, whether grown in frames or under cloches, a fact which speaks for itself for the cleanliness and tenderness of this Lettuce.

Broad Beans.—The long-pod section maturing almost as early as the smaller varieties, a sowing of these in boxes now would form a close succession to those sown in the open borders in November, and should the winter prove a severe one, and sharp frosts prevail while the latter are in flower, this second sowing will be almost as early, and will sometimes fill a vacancy provided these are brought on hardy in a late Peach house or vinery.

French Beans.—Plants raised from seeds sown in pots after this date will give better results than those sown in the autumn. A mixture consisting of manure from a spent Mushroom bed, and loam in equal parts, will be found a good compost for this crop, using pots seven or eight inches in diameter, which should be filled to within an inch of the top. I do not recommend the old method of half filling the pots, thus allowing for the application of a liberal top-dressing later on, because a percentage of the young plants get fatally bruised during the process. Do not afford any root-waterings until the seeds have germinated. Afford all the light possible and an atmospheric temperature of 55° to 60°. As the young plants continue to advance in growth they will need the support of a few short sticks.

Asparagus.—If forced Asparagus will be required in large quantities a liberal supply of roots had better be lifted whilst the ground is still free from frost. Although this vegetable is soon injured if the roots are exposed to the air, the plants will be found quite capable of withstanding a considerable amount of frost, thus, if more are lifted than are required for one batch, the surplus can be covered with an old mat or two or some long litter, just sufficient to exclude the air. If they are allowed to become frozen they will be found none the worse for this experience when it is necessary to place them in the frame for forcing.

Cauliflower.—Make a small sowing of this vegetable in a pan or box, and place it in a sunny position, close to the glass, in a cold frame. If this batch is intended to succeed a sowing made in autumn, the variety *Magnum Bonum* may be selected, but if no previous sowing has been made I would recommend the selection of *Early London*, or *First Crop*.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, JANUARY 14—
R.H.S. Exam. of Public Parks and Gdns. Employees.
Unit. Hort. Ben. & Prov. Soc. Com. meet.

TUESDAY, JANUARY 15—Nat. Amat. Gard. Assoc. meet.

WEDNESDAY, JANUARY 16—
Ann. meeting Brixton & Dist. Hort. Soc.

THURSDAY, JANUARY 17—Linnean Soc. meet.

SATURDAY, JANUARY 19—German Gard. Soc. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—88°8'.

ACTUAL TEMPERATURES:—

LONDON.—Wednesday, January 9 (6 P.M.): Max. 47°; Min. 44°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, January 10 (10 A.M.): Bar., 30°8'; Temp., 48°; Weather—Overcast.

PROVINCES.—Wednesday, January 9 (6 P.M.): Max. 49° Ireland S.W.; Min. 48° Scotland N.

SALES FOR THE ENSUING WEEK.

MONDAY AND FRIDAY—
Border Plants and Perennials, Azaleas, Roses, Hardy Bulbs, &c., at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.

WEDNESDAY—
Herbaceous and Border Plants, Hardy Bulbs, &c., at 12; 5,000 Roses at 1.50 & 4; Palms, Plants, Azaleas, Fruit Trees, &c., at 4; at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

FRIDAY—
Grand imported Cattleya Mossiae and other Orchids. Consignment of Odontoglossum crispum, &c., at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

The American Gooseberry-mildew.

Seldom, if ever, has the Horticultural Hall justified its existence more fully than on Tuesday last, when a discussion took place on the now engrossing topic of the American Gooseberry-mildew. There was a crowded meeting; scientists jostled with fruit-growers, market-gardeners were mixed up with members of Parliament and Government officials. The Market-Gardeners', Nurserymen's, and Farmers' Association took a leading part in organising the meeting. The discussion was free and unfettered. Sir Albert Rollit, in opening the proceedings, deprecated the passing of any formal resolution, and hence much more freedom of debate was secured than would have been the case if the society had been committed to any definite course of action. From what took place at the meeting, it seems evident that no amount of legislation could prevent the introduction of fungus spores. We have had a conspicuous illustration of this in the case of the Phylloxera, which, in spite of the most drastic regulations, has spread throughout the vine-growing countries of the world. If legislation could not stop the progress of a little insect relatively much bigger than a fungus spore, we may be sure it would be powerless to arrest the progress of such very minute bodies as the spores of a mildew. But, although we deprecate the attempt to get the Government to do what is either useless or what we ought to do for ourselves, that does not imply that nothing should be done. The cry of the growers is that something must be done. Undoubtedly it should, but it must be done by the only people capable of doing it effectively—that is, by the growers themselves. The mildew is in the country; we cannot keep it out, but we can lessen its ravages by watchfulness and prompt action. Stamping out is very effectual in certain diseases of animals, just as small-pox may be and is in some countries practically exterminated by vaccination, but it by no means follows that the stamping-out process could be efficiently carried out in the case of a mildew. Practical men must look to what is practically possible, not to what is utopian.

Adverting now to the proceedings on Tuesday, we may add that Professor Salmon laid his case lucidly and forcibly before the meeting, and illustrated his remarks by excellent lantern slides, some taken from the figures in the volume of the *Journal of the Royal Horticultural Society*, 1890, p. 140, and other works. It is not necessary for us to repeat now what Professor Salmon has already written at some length in our columns, from the year 1905 up to the present time, and elsewhere.* The discussion that followed was particularly interesting and useful as eliciting the views of the growers.

Mr. MASSEE prefaced his remarks by stating that what he was about to say was a matter of personal opinion, and did not in any sense represent the views held by the Board of Agriculture. He stated that he was the first to record the presence of the disease in this country, and had himself directed Mr. Salmon's attention to the matter. The dominant feature of Mr. Salmon's argument in favour of legislation was a quotation from an American expert, to the effect that English Gooseberries could not be grown on a commercial scale in America, owing to mildew. This quotation was quite correct, but Mr. Salmon omitted to mention, in his many communications to the Press, that it was made twenty years ago, at a period before spraying and preventive methods against diseases were evolved. Since that period equally emphatic statements have repeatedly appeared in official American publications to the effect that, owing to the efficacy of sprays, English Gooseberries were again in cultivation, and it was doubtful whether American varieties could maintain their supremacy. Such statements appear to have been overlooked by Mr. Salmon, as they are absent from his essays. Under the circumstances, Mr. Salmon's leading text must be considered as of historical interest only, and without meaning at the present day. Mr. Salmon's opinion that the disease is new to Europe, and introduced from America, is not supported by facts. The fungus was known in Ireland for some time before its identity was established, and its presence announced by Mr. Massee in the *Gardeners' Chronicle*, August 25, 1900, p. 143, fig. 39. Some European experts consider that the mildew is indigenous in Russia. It is a well-known fact that a given fungus may be present in a country for any length of time before it decides to become an injurious parasite, and, again, a given fungus may prove very injurious in one country and harmless in another. Special weather conditions often furnish the necessary stimulus that determines the commencement of a fungus on a parasitic career; such conditions were experienced in this country last year. Some Gooseberry growers have expressed the opinion that they have known the mildew in this country for many years. These may not be convincing, but they have not been proved to be wrong.

The one important point on which all are agreed, is the fact that the mildew is now established in this country. In Worcestershire, where it is fairly abundant, there is not the remotest evidence in support of the theory that it was introduced from the Continent. What remains to be done, and done promptly, is to practise those measures which have been proved to hold the disease in check in other countries. These are, autumn prunings; winter spraying with a solution of one pound of sulphate of copper dissolved in 25 gallons of water; spraying with liver of sulphur, half an ounce in a gallon of water, if the mildew appears when the leaves are young.

* The present danger threatening Gooseberry growers in Ireland, *Gardeners' Chronicle*, October 28, 1906, p. 305, E. S. Salmon. See also E. S. Salmon, in *Journal Horticultural Society*, London (1890), p. 140; Cooke, *Fungoid Pests of Cultivated Plants* (1906), p. 146.

In the absence of any evidence as to the introduction of mildew on imported bushes, at the moment of importation, and remembering the fact that so few Gooseberry bushes are imported under any circumstances, legislation may be considered as outside the sphere of usefulness in preventing the spread of the disease.

Finally, said Mr. Massee, it must be noted that, from Mr. Salmon's own statements, the mildew is most abundant in those countries where legislation against diseases is most stringent.

Mr. CECIL HOOPER and COL. LONG also spoke, and they were followed by Mr. HANS GÜSSOW, a well-known expert in plant diseases. Mr. Güssow said that, in his opinion, Mr. Salmon has gone much too far in his warnings against the possible damage that the American Gooseberry fungus may do. We have not only to look upon the development of the fungus—of any parasitic fungus—from the laboratory point of view, but we have to consider mainly the question from the side of practical experience. Practical experience has taught mycologists, as well as farmers and fruit-growers, that an attack due to a parasitic fungus only develops into an alarmingly severe epidemic when specially favourable conditions prevail. Such specially favourable conditions are mainly due to climate or superabundance of moisture in the air or to complete absence of moisture—drought. As long as no means are found—and he doubted if they ever would be found—of regulating these conditions, we shall have to deal with fungus epidemics. No legislation can prevent an epidemic due to the development of these microscopic organisms. When these organisms are present—and in the case of American Gooseberry-mildew we have often enough heard that it is present and has been present for some years in this country—an epidemic will only appear when special conditions favourable for the rapid development of the fungus set in. If such conditions do not prevail, no epidemic which need alarm our fruit-growers will ensue, and, in spite of a hundred Acts of Parliament, an epidemic will appear when such favourable conditions exist. Mr. Güssow said he could give a number of instances which would prove beyond doubt that, from the development of an attack of a parasitic fungus to an epidemic outbreak, special conditions are necessary. The fungus is present in this country, and it should be combated—by means of law, if possible—but the speaker considered it unnecessary—for he repeated an epidemic outbreak cannot be checked by law.

Mr. CHEAL spoke as to the necessity of being forewarned, and thanked Mr. Salmon for his efforts in this direction.

Mr. LOBJORT, in the course of an excellent speech, advocated the necessity of keeping out the disease by legislative enactments, and then of dealing with what is already in the country.

Mr. SALMON replied to the criticisms that had been passed on his paper, and a very hearty vote of thanks was accorded to him.

Various speakers laid stress on the differences of doctors, but those who adopted this line apparently failed to grasp the situation. There is no difference of opinion as to the nature of the fungus, nor as to its destructive habits. Where there is a diversity of opinion is as to the desirability or otherwise of seeking remedial aid from Parliament. This is no doubt desirable in some cases, but for the reasons already stated such aid would in this particular case most probably be ineffective. Watchfulness and prompt and specially combined action on the part of the growers, will do more than any Act of Parliament to keep the American Gooseberry-mildew in check.

LINNEAN SOCIETY.—The next general meeting will be held at 8 p.m. on Thursday, January 17, 1907. Papers:—1, Mr. W. BOTTING HEMSLEY, F.R.S., F.L.S., "Platanthera chlorantha, var. *tricalcarata*"; 2, the late Mr. C. B. CLARKE, F.R.S., F.L.S., "Acanthaceæ of insular Malaya"; 3, the Rev. T. R. R. STEBBING, F.R.S., Sec.L.S., "A Freshwater Isopod from Calcutta."

THE BOTANICAL MAGAZINE.—The first part of the New Year appears under the editorship of Col. PRAIN, the Director of the Royal Botanic Gardens—a happy augury for the continued successful conduct of the magazine. The plants figured are the following:—

LOMATIA FERRUGINEA (Rob. Brown), tab. 8,112.—This is a well-known greenhouse shrub, or small tree, with elegantly divided leaves. It is a native of Chile, but has not only proved hardy at Castlewellan, Co. Down, but flowered there in July 1906. The flowers are numerous, reddish, and arranged in axillary clusters. The description is furnished by Mr. SKAN.

ACONITUM GYMNAETHUM (Maximowicz), tab. 8,113.—A native of Tibet and Western China, and so remarkable in its structure as to suggest a monstrosity rather than a normal species. The sepals are spatulate with long claws and ovate blades of a violet colour twisted so as to expose the stamens. The hood, generally so conspicuous in Aconites, is relatively very small. Moreover, the plant is an annual. For these reasons Dr. STAFF, who contributes the description, places it in a separate section (*Gymnoaconitum*), of which it forms the sole representative. Kew.

VIBURNUM CARLESII (Hemsley), tab. 8,114.—See also Bean in *Gardeners' Chronicle*, 1906, i. p. 306, and also figure in *Gardeners' Chronicle*, October 11, 1907. Hardy at Kew.

TRICUSPIDARIA DEPENDENS (Ruiz and Pavon) tab. 8,115.—A Chilean shrub or tree belonging to the Tiliaceæ. Its ovate, shortly stalked, coriaceous leaves are pale on the under surface with a red midrib. The campanulate white flowers are borne singly on long peduncles proceeding from the axils of the leaves. It is hardy in parts of Cornwall and in south-west Ireland.

RENANTHERA ANNAMENSIS (Rolfe), tab. 8,116.—An Annamese Orchid described by Mr. ROLFE and distinguished from *R. imschootiana* by its much smaller flowers and spotted sepals. Perianth segments linear, oblong, yellow with red spots, lip much shorter than the segments spurred at the base and with a thick callus in the middle. Kew.

CALCUTTA BOTANIC GARDEN.—Captain GAGE, of the Indian medical service, has been appointed superintendent of the Royal Botanic Gardens, Calcutta. If we are not mistaken, this is the third time in succession that a graduate of Aberdeen has been appointed to this important position; certainly Sir GEORGE KING and Lt.-Col. PRAIN both hailed from the northern University.

G. C. CHURCHILL.—A very full and interesting account of the career of this gentleman is given in the last number of the *Kew Bulletin*. As was noted at the time of his decease, CHURCHILL had an exceptionally good knowledge of mountain-plants, and not only enriched the herbarium with very numerous dried specimens, but contributed very largely to the furnishing of the rock-garden at Kew. His assistance in checking the nomenclature is also warmly acknowledged. It is interesting to note that CHURCHILL had little faith in transitional forms apart from hybrids. "Recognised species have long been in a condition of perfect equilibrium with their environment, only disturbed by insect action to a limited extent, but when you begin to cultivate them new forces are set in action and produce no end of changes." What would he have thought of "mutation"?

PROF. HECKEL.—In recognition of the services to economic botany and to the French colonial possessions, it is proposed to present Prof. HECKEL with a special gold medal. A committee has been formed for the purpose of receiving subscriptions, which may be sent to Prof. DOMERGUE, 841, Rue Paradis, Marseilles, France.

THE "KEW BULLETIN."—A part recently issued is of great importance as affording an indication of more regular publication, and especially for its contents, which are of unusually varied interest. We shall take the opportunity of alluding to some of its contents on other occasions. Meanwhile we may add that the publication may be had from WYMAN & SONS, Fetter Lane, for the nominal price of fourpence.

"THE POTATO YEAR-BOOK."—The Potato has at length got a year book all to itself. Its economic importance, its history and scientific interest justify such a production. The present booklet is edited by Messrs. HORACE WRIGHT and W. H. ADSETT, as the official publication of the National Potato Society. It is published at Hatton House, Great Queen Street, and, whilst it is presented to members of the society, it may be procured by the profane for one shilling. Mr. MASSEE leads off with an account of the black-scab or warty disease of the Potato, now attributed to a fungus known as *Oedomyces leproides*, which is a much more destructive fungus than is commonly supposed. Gas lime, spread on the surface in April and lightly dug in in May, is the only remedy proposed. Mr. WALTER WRIGHT, the founder of the society, gives his opinion as to the six best Potatoes for table as follows:—Factor, Golden Worthy, Langworthy, Peacemaker, Up-to-Date, and Windsor Castle. Other papers are contributed by Mr. MALDEN, who finds fault with the business methods of some Irish growers and dealers, by Mr. FOSTER, Mr. WILLIAMSON, and Miss POAD. Prof. MIDDLETON contributes a valuable report on the experiments carried out near Cambridge. Amongst other points, Prof. MIDDLETON brings forward evidence to show the ill-effects of "Express Cultivation," and, now that the absurd "boom" is a thing of the past, it may be expected that this method of cultivation will only be employed for special purposes and under exceptional conditions. The reports of the trials in various counties are already valuable, and will become increasingly so as time goes on. Numerous portraits are given, and a table of contents that is called an index, but which hardly deserves such an appellation.

RETIREMENT OF MR. SANGWIN.—Many friends of Mr. SANGWIN, the veteran gardener and home steward of Trelissick, near Truro, writes a correspondent, will be interested to know of his retirement at the end of the present month. For close on 49 years he has enjoyed the esteem and confidence of his employer, and now he lays aside the harness to enjoy—for many years, we hope—a well-earned rest. It is given to few men to hold a responsible position for nearly half a century, and to fewer still to turn to account so successfully the natural features of an estate. Many visitors to Trelissick will remember the pond, with its huge Gunneras, its Nymphaeas, its numberless Richardias, and its bog plants flanked with magnificent Dicksonias. Besides acclimatising numerous sub-hardy plants, Mr. SANGWIN made a collection of hardy fruits, and was a most successful cultivator. Holding progressive ideas, his knowledge has been freely given, and his advice to many a young man, accompanied with droll stories, will long live in the memory of the recipients. Mr. C. DAY, of Haverland Hall Gardens, Norwich, will succeed Mr. SANGWIN.

PLANTS FROM THE CONGO.—The first part of the second volume of M. EMILE DE WILDEMAN'S work has now appeared. These "notices sur les plantes utiles ou interessantes de la flore du Congo," are accompanied with plates that are both interesting and valuable, as they are from photographs of the plants and their natural surroundings.

THE "BLANCARD" FUND.—Mr. C. HARMAN PAYNE, Foreign Secretary N.C.S., 141, Well-meadow Road, Catford, S.E., acknowledges further donations to this fund amounting to £3 13s.

POTATOS IN IRELAND.—The current number of *Irish Gardening* is largely devoted to articles concerning the cultivation of Potatoes in Ireland. The results of recent experiments have attested the value of Irish-grown Potatoes for "seed" purposes, and a vigorous effort is now being made to turn this circumstance to practical advantage. Directions are given to the farmers to grow the desired kinds, true to name and free from disease, to lift the crop early, and generally to study the requirements of the English market, even when they run counter to the regular practice adopted in Ireland.

THE CEDARS AT KEW.—London smoke, aided by that of Brentford and of Richmond, have contributed to the death of one of the few fine Cedars of Lebanon near the Pagoda. The sterile soil and the droughty summers of the last few years have, says the *Kew Bulletin*, hastened the destruction of these noble trees. Incidentally we may repeat our suggestion that the formation of a new arboretum at Wisley or elsewhere should occupy the attention of those concerned. We believe the R.H.S. has some intention of forming an arboretum, but, remembering the fate of the once famous collection at Chiswick, we should prefer to see a new arboretum placed under Government supervision.

THE "REVUE HORTICOLE."—On opening the number for January 1 we were confronted with the announcement that our colleague and friend of many years' standing, M. ED. ANDRE, has been obliged, on account of ill-health, to retire from the editorship. This is a matter of grave concern for his many friends. What M. ANDRE has done for botany, horticulture, and landscape-gardening is as well known and as highly appreciated by experts in this country as in France, so that very great sympathy will be felt both for him and for the management of the *Revue*. M. D. BOIS, who is called on to take the place of M. ANDRE, is also well known in this country for the zeal and capacity he has shown in horticultural and botanical matters. He entered the garden of the Museum d'Histoire Naturelle (Jardin des Plantes), and gradually rose to be assistant to the Professeur de Culture (Prof. MAX CORNU), and now to his successor. He succeeded DUCHARTRE as literary secretary to the Société Nationale d'Horticulture of France, and was deputed by the Government to visit Tonquin, where he made large collections and accumulated a mass of materials connected with economic botany and the cultivation of tropical plants. His publications are numerous, but perhaps the best known among them is the one published in collaboration with M. PAILLIEUX, entitled *Le Potager d'un Curieux*, a book full of interesting details concerning rare or little-known culinary plants. In conjunction with M. MAURICE DE VILMORIN, he has lately given us a catalogue raisonné of the trees and shrubs growing in M. DE VILMORIN'S property at Les Barres. M. BOIS will have the assistance of M. GRIGNAN, who has for some years been connected with the *Revue*, and whose communications amply justify the confidence reposed in him.

NATIONAL CONGRESS OF HORTICULTURE.—Prof. TRACY, of Washington, writes: "Those who essay to explore the ocean of the unknown should occasionally make observations and comparisons to ascertain just where they are. We can learn something of this through a mere physical exhibition of what has been and can be accomplished, but it is far more important that we come to an exact knowledge of the laws through and by which the results are obtained. This can only come through a conference between those who are studying these laws, for what seems a truth to one and, under a certain set of conditions, the experience of another under other conditions, may show is only a seeming truth. It is well, then, for all who are engaged in any particular line of study to meet occasionally for council, that they may ascertain just how much of that we think we know is actually so, to ascertain just how far we are in our voyage into the unknown. To this end the National Council of Horticulture have thought it wise to call for the meeting of a congress of the horticulturists of the world to assemble at Jamestown, Virginia, during the latter part of the exhibition to be held there in 1907 to commemorate the 400th anniversary of the first permanent English settlement in what is now the United States. The exact date of the meeting and the formal programme has not been decided upon, but will be announced later, but in the meantime we ask that all interested in progressive horticulture plan to attend the congress, and communicate with Mr. H. C. IRISH, Missouri Botanical Garden, St. Louis, Missouri, U.S.A., as to what definite subjects should be discussed."

BEAUTY IN ALOES.—There is a great deal of beauty in the flowers of many species of Aloe as may be seen in the succulent house at Kew, where there is a collection of about 190 species. On New Year's Day the following were in flower:—

A. arborescens	A. Lastii
A. aurantiaca	A. microstigma
A. Balneisil	A. natalensis
A. brachystachys	A. penduliflora
A. Cameroni	A. percrassa
A. chloroleuca	A. platylepis
A. ciliaris	A. pluridens
A. Kirkii	A. socotrana

ROYAL SCOTTISH ARBORICULTURAL SOCIETY.—The nineteenth volume of the *Transactions* of this society, or rather the first part of the twentieth, has been issued. It contains a large number of papers interesting to foresters. Among them is one by Dr. NISBET on the "Novar" system of combating the Larch disease by forming pure Larch plantations and thinning out after 16 to 20 years all the diseased trees, leaving only the soundest and most promising. How long they would remain sound is a question which will have to be solved before the practice is generally adopted. On the face of it, it seems as if the plantation of pure Larch must be the most sure method of propagating the pure fungus. Incidentally, we note that Dr. BORTHWICK reports the presence of the Larch fungus on the Japanese species, *Larix leptolepis*, and Sir HERBERT MAXWELL on *Pinus Laricio* and *P. silvestris*. The great value of the Douglas Fir is shown by the fact that, as compared with the Spruce, it "yields about twice the amount of timber with about three times the value," whilst its wood surpasses that of the Spruce in quality. It is satisfactory to hear of the progress made in planting the pit-mounds and spoil-banks in the Black Country. Conifers and Oaks do not thrive in the atmospheric conditions, but Willows, Birch, Alder, and many other trees "thrive quite well under the conditions prevailing in the Black Country." The part, as a whole, contains welcome evidence that the improvement and development of forestry is making progress.

PROFESSOR BAYLEY BALFOUR.—The last volume of the *Garden* is dedicated to Prof. BAYLEY BALFOUR, of whom a good portrait is given. Had he done nothing beyond introducing *Begonia socotrana* he would have deserved well of horticulture.

RHODODENDRON BARBATUM.—Sir HERBERT MAXWELL asks why this species is not more often grown, as it is as hardy as *R. ponticum*, though its brilliant scarlet flowers are apt to be injured by spring frosts if grown in exposed places.

AGRICULTURAL STATISTICS FOR 1906.—According to the report issued by the Board of Agriculture and Fisheries, cultivated or farmed land was reduced in 1906 by 20,000 acres diverted to residential or industrial use. As regards special crops, the area devoted to Potatoes was markedly decreased last year, and the area returned under Hops was the lowest on record. The acreage under small fruits and under orchards increased, the additions being in many, or nearly all, divisions of Great Britain, not in one or two districts only.

KEW NOTES.

PINUS CANARIENSIS AS A BEDDING PLANT.

[SEE SUPPLEMENTARY ILLUSTRATION.]

THE employment of a Conifer as a subject for summer bedding may seem strange to those who are unacquainted with this species. Even more

FIG. 15.—ODONTOGLOSSUM ALICEÆ X.
(See also page 31.)

interesting, perhaps, is the fact that some three dozen small specimens were used as dot plants in a bed of *Cotyledons* (*Echeverias*), with a groundwork of *Mesembryanthemums*, near No. 4 greenhouse at Kew. This may read as a very curious combination, but, from the remarks of numerous visitors, it is quite evident the bed was a success.

The plants were about 18 months old, and from 1 to 2 feet in height. At this stage of their growth the leaves are a silvery-grey colour, a character which they lose after the juvenile stage is past.

To keep the plants from making a too vigorous growth, and to facilitate lifting the plants at the end of the season, they are plunged in their pots. The average plant treated in this manner has, usually, to be watched very carefully to see that it does not suffer from a lack of water, not so the Canary Island Pine, which appears to thrive better with a minimum supply of water. The seeds germinate very readily, and its cultivation as a greenhouse foliage plant when in a small state is to be recommended.

A figure is given in the *Gardeners' Chronicle*, June 9, 1888, p. 721. It is a native of the Canary Islands, where it grows at an elevation

or from 5,000 to 7,000 feet. Excepting in one or two favoured spots in this country, the plant is not hardy, but requires the protection of a cool greenhouse in winter. Several fair-sized trees are, however, flourishing in the open air in Cornwall. D. D.

SEEDLING ODONTOGLOSSUMS AT CHELSEA.

I CAN almost remember the time when people were very sceptical of the existence of these in cultivation, and as recently as 1900 they were considered rather a "cut above" most *Orchid* seedlings, as witness the report of the *Orchid Review* (October, 1900, p. 314), where it is stated that I had shown two seedlings at once at the R.H.S.—"a specially interesting exhibit in the shape of two seedling *Odontoglossums* raised in his collection."

To-day this reads quite amusingly when we know they are being raised and grown by hundreds almost in the very heart of London upon the dead flat, marshy swamps of Chelsea by Mr. Lakin, for Messrs. W. Bull & Sons.

I have watched his strenuous efforts with great interest for the past three years, and am pleased to be able to chronicle his unmistakable success, as is indisputably proved by the seedling house.

All the plants on the left side and the three front rows on the right of this house are "*Odontos*," or "*Odontios*," the remainder on the right side are either "*Seed Beds*," or "*fine things*." There are 900 pots containing over 1,200 little plants. I consider this a remarkable result to have been achieved in the period Mr. Lakin has been in charge, he having assumed his office in September, 1901.

The first *Odontoglossum* seedling to bloom was O. *Aliceæ* (*Edwardii* × *crispo-Harryanum*), which was purchased and shown by J. Gurney Fowler, Esq., at the R.H.S. on the 8th inst., when it was awarded an Award of Merit (fig. 15). It has been but 4, 7/12 years from crossing to blooming, a rapid rate for an *Edwardii* cross, the actual record being "crossed May 5, 1902; sown July 14, 1903; bloomed December 12, 1906."

The photographic reproduction of this beautiful thing once more tells us the immensely powerful influence O. *Edwardii* will have upon the future of *Odontoglossum* hybrids, an influence only equalled or excelled by that of *Cochlioda Noezliana*. It is an interesting speculation upon the future to picture a while hence the result of the union of the best *Cochlioda* and *Edwardii* hybrids. What will they give?

Not only in *Odontoglossums* has Mr. Lakin been successful, for he has remodelled the houses, turned out almost all the species, and nearly filled them again with some 25,000 *Cattleya* or *Lælia*, *Cypripedium* and *Sophrontis* hybrids. There is not apparently much difficulty in raising these, as the seed-pans testify.

Mr. Lakin is to be heartily congratulated upon the results he has achieved for his firm, and there is no reason why his successes should stop, for he is given a free hand and uses it intelligently, as his organisation amply testifies. *de B. Crawshaw.*

NOVEMBER AND DECEMBER IN MY FLORIDA GARDEN.

(Continued from page 2.)

LEONOTIS leonurus, the Lion's Tail, grows with equal vigour, large plants in full bloom being a beautiful sight. It is a fine companion to the Lantana, but it spreads still more and grows larger and taller than that flower. Though scarcely ever out of bloom, it is at its best in November and December. Cosmos "*Klondike*" is a very stately and brilliant autumn bloomer, and *Petunias*, *Tagetes*, *Torenia*s, and *Dahlia*s, but particularly *Chrysanthemums*, form a sheet of colour where they are carefully tended and where the soil is rich and fairly moist.

ALLAMANDAS.

The *Allamandas* are never out of bloom, but by November they have finished their growths, and the bushes are then covered from top to bottom with the large, finely-shaped and brilliant yellow flowers. They are common garden

SEEDLING PLANTS OF *PINUS CANARIENSIS* USED FOR BEDDING TOGETHER
WITH SUCCULENT PLANTS.

Temple Press Ltd., Printers, 7-15, Rosebery Avenue, London, E.C.

plants in Florida, especially *Allamanda Hendersonii*, which forms a rampant climber, and the burly *A. neriifolia*, which is popularly known as the "Golden Bells." Other species, like *A. Sobottii* and *A. Williamsii*, are equally floriferous and easily grown, but they are rarely met with here. Large plants frequently ripen their seeds, which are contained in a burr-like prickly fruit, which varies in the different species, from the size of a small Plum to that of a Walnut. At the present time several of my plants are both in flower and in fruit.

HIBISCUS, DATURAS, CESTRUM, &C.

A bed of the different varieties of the Chinese Hibiscus (*Hibiscus rosa-sinensis*) is an object of great beauty, the refulgent and dazzling hues of the large but fugacious flowers creating an enthusiasm in every lover of the beautiful. The single varieties are luxuriant growers, and will attain a height of 10 to 12 feet in rich soil, while the double kinds are dwarfer. Like the Allamandas, Jacobinias, Lantanas, and Lasiandras, the Hibiscus is a sun worshipper, thriving only and revelling in the full sunshine, and in consequence reaching here its greatest perfection.

Near my study window, a plant of the Angel's Trumpet (*Datura suaveolens*) has attained very imposing dimensions. I inhale the fragrance of its chaste and lily-like blossoms, which are almost pure white in colour; while writing these lines, several hundred flowers are suspended from its massive branches. Being a gross feeder it requires a large amount of stimulant rich in ammonia and phosphoric acid, and a bounteous supply of water. These plants frequently attain a height of from 12 to 15 feet. Near this specimen, a large *Clivia cyrtanthiflora* grows in perfection, and is now flowering most profusely, and on the opposite side of the *Datura*, *Agapanthus umbellatus* finds a place. Both these plants are natives of South Africa, but while the *Clivia*—a hybrid between *C. miniata* and *C. nobile*—is in full vigour, the *Agapanthus* shows scarcely any sign of growth. The charming sweetness of the Angel's Trumpet mingles with the strong and exceedingly delicious perfume of a large flowering specimen of the night-blooming Jasmine (*Cestrum nocturnum*) and the equally powerful odour of *Cestrum parqui*. The first-named species is a tall, dense-growing shrub, blooming four or five times during the year, its display of the inconspicuous greenish-white flowers lasting only for three or four days. The second species is a dwarf grower, with large crimped foliage of a very dark green colour. The flowers are larger and greener in hue, lasting in full freshness for about a week or ten days. Their perfume is overpowering during the night-time. *H. Nearling Gotha, Florida.*

(To be continued.)

PLANT-NOVELTIES IN 1906.

(Continued from page 4.)

ORCHIDS FROM NURSERYMEN.

Messrs. SANDER & SONS, St. Albans, hold the lead, especially in the matter of imported new species, their ardour in collecting abroad not being extinguished by the ever increasing numbers of their garden hybrids. Among their new species, the best are *Arachnanthe annamensis*, for which the Curator of the Royal Botanic Gardens, Glasnevin, received a First-Class Certificate; *Cymbidium erythrostylum*, *C. insigne*, the pure-white *Aerides virens* Sanderæ; the very fine snow-white *Cœlogyne Mooreana*; and the large Annam form of *Phaius maculatus*, *Lælia majalis* alba shown at the Holland House exhibition; *Cattleya Warscewiczii saturata* and *C. Trianaei* "J. Gurney Fowler," two very handsome forms; also *Cypripedium Godefroyæ leucociliatum* Hodgkinsii, a very large and handsomely-blotched variety. The hybrids for which awards were given to Messrs. SANDER during 1906 were *Cymbidium Holfordianum*, *Brasso-Cattleya The Baron*, and *Odontoglossum Fowlerianum*, which obtained First-Class Certificates; and *Cypripedium* "Earl of Tanker-

ville," *C. Baron Schröder ardens*, *C. Victory*, *Brasso-Cattleya striata superba*, *Odontoglossum Fletcherianum*, *Lælio-Cattleya elegans* His Majesty, L.-C. Golden Beauty, and L.-C. Canhamiana Meteor, which received Awards of Merit; also the very fine and distinct *Odontoglossum amabile* "Royal Sovereign," shown at the Holland House exhibition, with a number of other novelties not yet sufficiently developed to come into this list.

Messrs. CHARLESWORTH & Co., Heaton, Bradford, have been among the most successful exhibitors of hybrid novelties of the past year, receiving First-Class Certificates for *Odontoglossum amabile* "John Bradshaw," *Cypripedium Ossulstoni* "W. H. Hatcher"—both shown on April 17—and *Cattleya Claudian*. They gained also Awards of Merit for *Cattleya Octave Doin*, *Cymbidium eburneo-giganteum*, *Odontioda heatonensis*, and its variety "St. Vincent"; *Odontioda Bohnhoffiæ*, *Lælio-Cattleya Sunray superba*, L.-C. *illustris magnifica*, *Odontoglossum Eurydice* and *Phalænopsis violacea*, Heaton variety.

Messrs. JAS. VEITCH & SONS, LTD., King's Road, Chelsea, secured a First-Class Certificate for *Lælio-Brasso-Cattleya Veitchii*, a very handsome secondary hybrid of *Brassavola Digbyana*, and *Brasso-Cattleya Pyrrha*.

Messrs. HUGH LOW & Co. introduced in *Cypripedium Fletcherianum* one of the finest *Cypripediums* of the year, and their *Cattleya Mendelii* Mercury was a noble form.

Messrs. JAS. CYPHER & SONS, Cheltenham, famous for *Dendrobiums*, exhibited a model form in *D. nobile* Perfection.

Messrs. J. W. MOORE, LTD., Rawdon, Leeds, commenced their career as exhibitors with

M. JULES HYE DE CROM, Ghent, for *Odontoglossum percultum* Juno, shown at the Temple Show, was given an Award of Merit; and occasional novelties came from other Continental raisers.

The following Orchids were illustrated in the *Gardeners' Chronicle*:—

- Angræcum Kotschyi*, June 16, p. 379.
- Arachnanthe annamensis*, May 12, p. 290.
- Brasso-Cattleya* Mrs. Francis Wellesley, supp., June 30.
- Brasso-Cattleya The Baron*, supp., May 5.
- Bulbophyllum virescens*, supp., Oct. 13.
- Cattleya Schröderæ alba*, May 12, p. 300.
- Cattleya Bowringiana* (specimen), Feb. 24, p. 114.
- Cymbidium erythrostylum*, Oct. 27, p. 286.
- Cypripedium Alcibiades magnificum*, Jan. 27, p. 52.
- Cypripedium Fletcherianum*, Oct. 13, p. 254.
- Cypripedium Germaine Opoix*, Westfield variety, Dec. 15, p. 410.
- Cypripedium Godefroyæ Hodgkinsii*, July 14, p. 32.
- Cypripedium Harri-Leeanum*, Park Lodge variety, Sept. 1, p. 166.
- Cypripedium insigne* Sanderæ (house of), Dec. 1, p. 367.
- Cypripedium Thalia* Mrs. Francis Wellesley, Jan. 6, p. 5.
- Cypripedium tessellatum rubens*, Jan. 13, p. 19.
- Cypripedium tibeticum*, June 2, p. 347.
- Dendrobium Wiganianum*, Gatton Park variety, April 7, p. 219.
- Dendrobium chrysanthum* (1,000 flowers), Dec. 1, p. 374.
- Grammatophyllum speciosum*, Aug. 4, p. 86.

FIG. 16.—VIOLETS CULTIVATED IN POTS AT COKETHORPE PARK GARDENS.

(For text see page 28.)

several distinct novelties, of which *Cattleya Marstoniæ superba* secured an Award of Merit.

Messrs. McBEAN, Cooksbridge, the famous *Odontoglossum* specialists, had for their best novelty *Odontoglossum crispum* Laburnum, a very remarkable variety with Laburnum-yellow blooms, and *Lælia anceps* Fascinator.

Mr. WHATELEY, Kenilworth, had the handsomely-blotched *Odontoglossum crispum* Whatelyæ.

Messrs. STANLEY, Southgate, showed the fine yellow *Oncidium Stanleyi*; Messrs. SUTTON & SONS, Reading, the pretty *Cœlogyne yunnanensis*. A few other novelties have been shown by various exhibitors.

Continental exhibits of special merit have not been numerous during 1906.

M. A. A. PEETERS, Brussels, secured two First-Class Certificates for varieties of his beautiful *Odontoglossum Lambeauianum*; another for the showy *Cattleya labiata* Peetersii, and an Award of Merit for his pure-white *Cattleya* Mrs. Myra Peeters.

M. CHAS. VUYLSTEKE, Ghent, has shown several fine *Odontoglossums* during the year, securing awards for *Odontoglossums* *percultum* Meteor and Juno.

Lælia Nemesis, Tring Park variety, Mar. 3, p. 131.

(To be continued.)

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

CULTURE OF VIOLETS IN POTS.—In reference to the correspondence which has recently appeared in the columns of the *Gardeners' Chronicle* respecting the culture of Violets, I fully agree with Mr. Brewer as to the success to be obtained by growing the plants in pots for flowering in winter. As specimens in pots they form a welcome change from other plants for use in house decoration, and in the conservatory. They are more under control than when planted out in frames, being more readily inspected for decaying leaves, insect pests, slugs, caterpillars, and woodlice, which at times cause them much injury, eating away both leaves and flowers. I enclose a photograph (see fig. 16), which was taken in the first week in December, and which shows part of a batch of plants growing in 6 and 7-inch pots. The plants have been in full bloom since the middle of October, and some of them have still as many as 12 fully-developed blooms upon them, as well as numerous buds. The varieties are Neapolitan and Marie Louise. I also enclose a photograph of the variety Neapolitan (see fig. 17) growing in a cold frame, and from which we have been picking flowers from the end of August, which was some weeks before they were put into the frames. I find that the white Comte de Brazza is more delicate in constitution than any I have to deal with. *F. E. Stokes, Cokethorpe Park Gardens, Oxon, December 17, 1906.*

INJURY BY RATS AND PHEASANTS.—Rats during the recent hard weather have ruined hundreds of Brussels Sprouts in these gardens, eating the stems through and the core of same to the depth of 2 and 3 inches. They also obtained entrance to a vinery and nibbled off all the shoots from some Chrysanthemum plants. Pheasants here are also very troublesome. On one Saturday in last spring I had about 500 plants of Cauliflower transplanted to a plot of ground from the frames, and on the following Monday there was not a leaf left. I find the only way to grow these vegetables is to protect all the plants with netting. Pheasants are very fond of Seakale sets when planted, and they will pull them out and eat every morsel. They found the New Potatoes and made great havoc by scratching them out and half eating them, then leaving the tubers and passing on to more. Pheasants have also a great liking for the herbaceous plants, laying their eggs under Asters, Pæonies, &c. A bed of early Carrots was taken possession of by one hen pheasant, and when the Carrots were ready for pulling they had to be left until the young pheasants were on the move. *R. Mountford, The Gardens, Norton Priory, Runcorn, Cheshire.*

LIRIODENDRON TULIPIFERUM OR SADDLE-LEAF TULIP TREE.—When looking through the ninth and last volume of a fine old Dutch botanical work, published at Amsterdam in 1748, and entitled *Opus Botanicum*, by W. C. Weinmann, I came across, on plate 997, a portrait of a beautiful form of this well-known, handsome flowering tree which was quite new and unknown to me. In the ordinary form the flowers resemble those of a green Tulip, with golden yellow flakes and markings, but usually produced only on the upper branches of old trees. As in a young state this tree never blooms in this country, they are seldom seen by anyone. In the form figured in the above-named old Dutch work under the name of Tulipifera Virginiana tripartito Aceris folio, the centre of the flower is bright rose coloured with streaks of the same colour down the centres of the petals, forming altogether a most beautiful flower. On the next plate is figured, under the same specific name, with the words Anthera filamentosa added, the ordinary form with yellow and green flowers. The text of the book being all in the Dutch language I can learn nothing from it. It would be interesting to know if this rosy form is still in cultivation. *W. E. Gumbleton.*

FRUITS OF JASMINUM OFFICINALE.—I enclose some fruits of the common white Jasmine belonging to a neighbour of mine, who has two plants: the one planted on a north aspect, the other facing the south. Both the trees were laden with fruits this autumn, and as this is a very unusual occurrence, I am sending some for your inspection. *F. Mitten, Hurstpierpoint, Hassocks.*

MEGACARPÆA ARMENA.—In reference to a note in last week's issue, by F. M., this name is evidently meant for Megacaryon armenum. The plant comes from Turkish Armenia, and the description given fits the plant very well. *M. armenum* was figured in the *Gardeners' Chronicle*, 1897, ii., p. 226, f. 67-8, under the name of *M. orientale*. In the *Kew Index* *M. orientale* is referred to as *M. armenum*. The genus is monotypic, and this plant has also been known under the names of *Echium orientale* and *Onosma megalospermum*. It is certainly a stately plant, and produces a long succession of flowers. *W. I.*

SWEET PEAS.—The enclosed Sweet Peas are some of my new winter-flowering strain. They flower profusely throughout the winter. We have more than 40 different shades that have originated in these nurseries. *C. Engelmann, Saffron Walden.* [These appear to be of the same type as were first sent us in April, 1904 by Mr. Clarke (gr. to Lady Plowden), who obtained the seeds from a gentleman in Algeria.—Ed.]

from which reliable intelligence may be obtained. Formerly, when I wanted to gain any particular information regarding park work, I have found great difficulty in selecting any work from which such information could be had, although I have frequented some of London's largest libraries in search of it. This shows how handicapped those subordinate employees in the public parks have been who are endeavouring to qualify for promotion. We have plenty of opportunities of gaining a thorough knowledge of practical gardening, but with such matters as I anticipate Mr. Pettigrew, and I hope others, will deal with, no opportunities have occurred until the present. Now they are forthcoming, they will be appreciated by myself, and, I have good reasons for believing, by many others also. *Puisse.* [Please do your part also.—Ed.]

COLD STORAGE.—The Canadian Government, in order to encourage the provision of cold storage, is reported in the *Times* of December 31 to have arranged a scheme whereby builders of

FIG. 17.—VIOLET CULTURE IN FRAMES AT COKETHORPE PARK.

PUBLIC-PARK MANAGEMENT.—I feel sure that many officials and their subordinates in the public parks in the United Kingdom are pleased to see that you have allotted a portion of the *Gardeners' Chronicle* for the publication of a series of articles on the details appertaining to park-management. Only those who are employed in such places have any idea of the wide experience that is necessary, and the arduous duties which the position of superintendent entails on those who fill such positions. The motto Mr. Pettigrew has cited, "Efficiency with Economy," is undoubtedly one that appeals to the majority of those who are responsible for the proper maintenance of our public parks, and those directly concerned with the carrying out of such practices that will end in such a result being achieved. In the articles which Mr. Pettigrew is contributing, those who are endeavouring to fit themselves for filling such positions as park superintendent, foreman, etc., will find much valuable information. I am an employee in one of London's largest parks, and so belong to the above-mentioned class. I have a pressing need for a publication of some kind or other

new cold storage warehouses during the present fiscal year will receive grants in aid, amounting to 10 per cent. of the cost, and further grants in future years amounting in the aggregate to 30 per cent. of the capital invested. When will our own Government encourage fruit growers and farmers in a similar manner? Cold storage houses in all our principal towns would be an inestimable boon to the above industries, and not less so to all private gardeners within reach of them, and would probably have a beneficial effect on the general health of the inhabitants. *W. H. Divers.*

STORM IN CO. MAYO.—It may interest some readers of the *Gardeners' Chronicle* to hear that a real blizzard began towards evening on December 25, and snow fell during the night and continued more or less during the remaining part of the week with rather severe frost. There was quite 8 inches deep of snow, and in many places the drifts were 6 to 7 feet deep. I am told it is the most severe frost and the heaviest snowfall that have occurred here for the last 15 years. *Thos. Sunnucks, Gardener to C. Scrase Dickens, Esq., Coraun, Achill, West Coast of Ireland.*

BEGONIA GLOIRE DE LORRAINE RAISED FROM SEED.—In reply to H. R. and A. J. W., p. 445, self-sown seeds of both white and pink varieties, germinated on the surface of the soil in the pans in which the old plants were growing. These plants which produced the seed were suspended from a roof of a corridor during the winter months, but about the middle of January, 1906, they were taken down, and after shortening back the growths a little, they were placed in a temperature of 70-75° for the purpose of encouraging the development of basal shoots for cuttings. In the course of a few weeks we discovered seedlings germinating on the surface of the pans, from whence they were afterwards transferred, as they increased in size, to small thimble pots. I attribute the development of the fertile seeds solely to the conditions under which the plants had been grown while in the flowering stage, as in no other

phere of a temperature ranging from 60° to 70°. They were raised from cuttings last spring, have been a mass of bloom since the end of September, and promise to continue effective for two months longer. I have about 30 pods of seed in different stages of ripening, but it rather a bad time of year for seed-ripening. Does semi-starvation help to produce these female blooms, which I notice are all terminals? I hope to sow seeds by the end of the present month. As the seeds look very bright, I do not see any difficulty in raising a good batch. H. R., Cardiff, asks if seed is procured otherwise than by self-fertilisation. But does any single Begonia require to be artificially fertilised except for crossing purposes? I am not very clear on that point, and should be pleased to know. I should think these flowers of Gloire de Lorraine would be easily fertilised, seeing the

he did show it up to be a serious pest; yet it was so obvious, after hearing Mr. Massee for the defence, that this mildew is not such a terrible criminal after all? Prohibition is the cry of the prosecution, but Mr. Massee showed us that where prohibition of importation is severest there is the mildew the severest also. Is it not possible that spores of this fungus can be brought across the sea in the air without the aid of host plants? If that be not so, how first came, and so widely developed simultaneously, the Potato fungus? But if Mr. Salmon rang the alarm bell to growers of Gooseberries, certainly Mr. Massee did much to calm their fears by his statements as to what remedial measures had done in checking the mildew. Here indeed lies the whole gist of the matter. One section of growers alarmed by Mr. Salmon's teaching cries aloud to the government to come and save them. Cooler heads heeding Mr. Massee's advice adopt practical measures of a remedial kind and practically stamp out the evil. D.

LAW NOTE.

LEGISLATION AGAINST PLANT DISEASE.

It has probably occurred to many of those interested in horticulture and agriculture to wonder why steps have not long since been provided to enable the Board of Agriculture to deal on suitable lines with the ravages of any disease likely to affect plant life. Experts will doubtless be glad therefore to hear that a Bill is now being drafted in the legal department of the Board of Agriculture for the purpose of providing the Board with the powers necessary to deal with the importation as well as the extermination of all diseases of a nature likely to spread to the detriment of plant life in this country.

It is, of course, well known that some years ago an Act was passed for the purpose of dealing with the danger arising from the *Doryphora decemlineata*, commonly called the Colorado beetle. It is now proposed to extend the provisions of this Act to other diseases of the nature above referred to, and a few notes on the subject of this Act may therefore prove of interest.

It is hoped to give more detailed particulars of the proposed Bill as soon as the formal draft has been finally settled. Meanwhile, nurserymen and market-gardeners should bear in mind that the best opportunity of influencing legislation arises while any proposed Bill is being drafted. After the Bill has once been carried into the House of Commons, it is naturally more difficult to influence one political party or the other in favour of any suggested amendment. Growers should therefore lose no time in considering very carefully whether the present opportunity should be utilised of seeking to influence, in any other respect, legislation in the direction mentioned, as the Bill will, of course, be very far reaching in its effects.

Whether the Board of Agriculture will apply the machinery thus to be provided to dealing with the question of the American Gooseberry-mildew yet remains to be seen, but parties on every side will presumably be unanimous in agreeing that legal machinery against disease of any kind ought to be created without waiting until an epidemic has actually broken out. There is no doubt that the action contemplated by the Board of Agriculture is to be taken in consequence of a widespread feeling in the trade on this point, and whatever may have been the history of past events, it certainly seems only fair to the Board to note that, at the present time, there seems to be a real desire on the part of the Board to keep in touch with matters on which the trade is found to be more or less unanimous. An Act to amend the present Market-Gardeners' Compensation Act will shortly be brought forward, and the opportunity will then be seized of extending to nurserymen various benefits already enjoyed by market-gardeners under the existing Acts. Again, we now find that in response to the demand for legislation against plant disease generally, the necessary powers are to be promptly applied for. Those who are anxious to see legislative measures in more than one direction passed for the benefit of the trade, should, instead of crying out about the apathy of officialdom, continue their efforts to combine unanimously in bringing their requirements before those officials who are deputed to pay special attention to their interests. H. Morgan Veitch.

FIG. 18.—BEGONIA GLOIRE DE LORRAINE AT CLEVELLEY, SOME OF WHICH WERE RAISED FROM SEEDS.

instance did I discover a single seedling germinating in any of the pans of other plants of this Begonia, although others were saved for supplying cuttings, but these had been flowered under different conditions than those in the corridor. The plants that produced the seedlings had been kept in a semi-starved, dry, arid condition in the corridor, in which the temperature rarely exceeded 50-55°, and during the time that the Chrysanthemums were occupying the structure, a very plentiful supply of ventilation was provided. Under these conditions is it not possible that the pollen may have become more readily distributed? The plants, owing to their being suspended overhead with Chrysanthemums beneath them, were kept very much drier at their roots than those we have growing in the warmer structure. Since the calendar containing this information was published, I have had a photograph of the house taken, which is 40 feet long, but unfortunately it does not lend itself well to the camera, fig. 18. The seedlings are those immediately on the end of the stage in the photo. I shall be pleased to hear from other correspondents their experience in the matter of Begonia Gloire de Lorraine seedling. Benjamin Cromwell, Clevelley Gardens, Allerton. Liverpool.

I have grown this Begonia more or less well for several years, but have never noticed any seed pods till this year. The plants are growing in 5-inch pots hanging from shelves in a span-roofed orchid-house in a moist atmos-

clusters of male blooms there are to one female. W. N., Spaxton, Bridgwater.

WATER TANKS.—During bad weather in winter, when work in the out-door garden is partially suspended, some of the available labour from this source may be utilised in cleaning out the water tanks in the plant and fruit houses. At this season such receptacles usually contain a large amount of black sediment, which is washed from the roof glass from time to time. The plant-grower will realise how much cleaner his plants will be, and also the woodwork of the structures, if syringings are always done with clean water. B. Cromwell.

THE GOOSEBERRY-MILDEW.—In regard to Mr. Salmon's lecture at the R.H.S. meeting on Tuesday last, Mr. Salmon merits all thanks for the able way in which he may be said to have opened the case as prosecutor of the Gooseberry-mildew, and

SOCIETIES.

ROYAL HORTICULTURAL.

JANUARY 8.—The first meeting of this society in the new year was held on this date, a moderate display of flowers and fruits being staged. Among the exhibits were several fine groups of Orchids, greenhouse flowers, stove plants, Ferns, Alpines, &c., and three large collections of fruits, principally of Apples and Pears. The FLORAL COMMITTEE had no novelty worthy of an award brought to its notice, but the ORCHID COMMITTEE granted one First-Class Certificate and four Awards of Merit, while the FRUIT & VEGETABLE COMMITTEE gave an Award of Merit to a Pear which was sent in the first instance for naming, and in which the Committee recognised a new variety of much merit. Although the weather was exceptionally fine, the attendance of the public was meagre. At the meeting held in the afternoon a very large number of new Fellows were added to the roll of the Society, and a lecture on the American Gooseberry-mildew was delivered by Mr. Salmon, which evoked an interesting discussion.

Floral Committee.

Present: H. B. May, Esq. (in the chair); and Messrs. G. Paul, J. Walker, T. W. Turner, J. Green, Geo. Nicholson, G. Reuthe, C. E. Shea, C. Jeffries, W. Cuthbertson, C. E. Pearson, W. P. Thompson, E. H. Jenkins, J. Bennett Pöe, W. J. James, Wm. Howe, John Jennings, J. F. McLeod, C. R. Fielder, C. Blick, R. Wallace, Herbert Cutbush, Arthur R. Goodwin, Chas. Dixon, and C. T. Druery.

Rev. H. BUCKSTON, Sutton Hall, Etwell, Derby (gr. Mr. A. Sharnbrook), displayed a large number of Cyclamen, all of which were plentifully flowered, and of vigorous growth, not quite so compact in habit as is sometimes seen, but collectively a very pleasing group. The colours were representative of all the shades found in this useful winter-flowering subject. (Silver Flora Medal.)

Messrs. HUGH LOW & Co., Bush Hill Park, Enfield, N., also exhibited a number of these plants, among which was the variety Low's Salmon, a very compact, free-flowering kind, with clear, salmon-tinted petals. Messrs. HUGH LOW also staged a number of Carnations of the American or winter-flowering type, and plants of *Rondeletia speciosa*. (Silver Banksian Medal.)

Messrs. JAMES VEITCH & SONS, Ltd., King's Road, Chelsea, exhibited spikes of the blue *Coleus thyrsoideus*, a batch of *Jacobinia chrysostephana*, *Begonia Winter Cheer*, and a few other greenhouse flowering plants, and, as a separate exhibit, a semi-circular arranged group of the new *Buddleia asiatica*, carrying its slender panicles of creamy-white flowers on the ends of the long growth. Included in this exhibit was a plant of *Hamamelis arborea*, and another of *Camellia Sasanqua*, both in flower. (Silver Flora Medal.)

Another group of this new *Buddleia* was shown by Mr. L. R. RUSSELL, Richmond Nurseries, Richmond, Surrey, and among these plants were interspersed ornamental-leaved hardy shrubs, such as *Eleagnus*, *Euonymus*, *Aucuba*, *Garrya*, &c.

Messrs. H. CANNELL & SONS, Swanley, Kent, showed several pyramidal-trained plants of *Begonias Gloire de Lorraine* and *Turnford Hall*, and sprays of *Moschosma riparium* in pretty glass vases.

A batch of the scarlet *Euphorbia jacquiniiflora*, shown by Lord ALDENHAM, Elstree (gr. Mr. Ed. Beckett), formed one of the brightest displays in the hall. The individual flowers were remarkably well coloured, but the sprays were not of exceptional length. (Silver Banksian Medal.)

Mr. H. B. MAY, Dyson's Lane Nurseries, Upper Edmonton, showed many handsome Ferns, including the beautiful *Nephrolepis Piersoni* elegantissima and the rare *Polypodium ioides ramocristatum*. Specimens of *Adiantum Farleyense* were of exceptional merit. Adjoining the Ferns were *Begonias*, *Erica melanthera*, and small but well-berried examples of *Aucuba vera*. (Silver-Gilt Banksian Medal.)

Messrs. WM. BULL & SON, King's Road, Chelsea, staged a number of ornamental-leaved stove and greenhouse plants.

A new *Chrysanthemum*, a pink sport from the

white Mrs. J. Thompson, was shown by Mr. H. WHATELEY, Spring Gardens, Isleworth. The blooms were remarkably fresh, considering the lateness of the season for these flowers, and the variety should prove an acquisition for market purposes.

Messrs. WM. CUTBUSH & SONS, Highgate, London, N., showed seasonable alpine plants in flower, Irises, *Sternbergia*, *Tussilago fragrans*, *Adonis amurensis*, &c., and a number of early-flowering shrubs, including *Hamamelis Zuccarinii*, *Jasminum nudiflorum*, *Prunus triloba*, *Daphne Mezereum album*, &c. Messrs. CUTBUSH also contributed an excellent display of Carnations. (Silver Flora Medal.)

Alpine plants were also shown by Messrs. J. PEED & SON, Norwood; Misses HOPKINS, Hill-side Nursery, Barming, near Maidstone; and Mr. REUTHE, Keston, Kent.

Some very heavily-berried sprays of *Pernettya mucronata* were shown by A. KINGSMILL, Esq., Harrow Weald, Middlesex.

Mr. FRANK GALESWORTHY, Green Lane Farm, Chertsey, Surrey, displayed a number of paintings of floral subjects. (Silver Banksian Medal.)

Orchid Committee.

Present: J. Gurney Fowler, Esq. (in the chair); and Messrs. Jas. O'Brien (hon. sec.), Harry J. Veitch, de B. Crawshaw, H. Little, W. Boxall, Francis Wellesley, W. Bolton, H. G. Morris, H. A. Tracy, H. G. Alexander, W. H. Young, J. Charlesworth, W. Cobb, H. T. Pitt, A. Dye, A. A. McBean, F. M. Ogilvie, T. W. Bond, and W. A. Biney.

Messrs. CHARLESWORTH & Co., Heaton, Bradford, staged a fine group, in which their hybrid Orchids were displayed, a very remarkable new plant, *Odontioda Bradshawia* × (see Awards), forming the centre of attraction. In the group several plants of *Cattleya Octave Doin* were very beautiful; and the Heaton strain of *Odontoglossum Rolfeae* excellent and varied in colour. Also *O. Othello*, the elegant *O. Phoebe*, with a magnificent spike of pretty, white flowers spotted with dark red; varieties of *Brasso-Cattleya*, *Laelio-Cattleya Andromeda*, *L.-C. Lydia* and other hybrid *Cattleyas* and *Laelio-Cattleyas*. The species embraced several of the handsome and fragrant *Trichopilia suavis*, a nicely-flowered plant of the rare *Trichopilia brevis*, with yellow sepals and petals barred with red, and showy white lip. *Laelia Gouldiana*, *Saccolabium giganteum*, &c. (Silver Flora Medal.)

Major G. L. HOLFORD, C.I.E., C.V.O., Westnort, Tetbury (gr. Mr. H. G. Alexander), showed a selection of new hybrid Orchids, for two of which see Awards. It included *Brasso-Cattleya Madame Hye*, Westonbirt variety (*C. Harrisoniana* × *B. Digbyana*), an improvement on that for which he received an Award of Merit at the Holland House show; *Cypripedium Vandeyck* (*C. hirsutissimum* hybrid × *Mons. de Curte*), with dark rose-coloured dorsal sepal edged with white; *C. aureum* (*Eidippe*), with a purple dorsal sepal having the upper third white; *C. aureum* *Hyeannum*, and *C. illustre* (*Lathamianum* × *nitens*).

FRANCIS WELLESLEY, Esq., Westfield, Woking, showed *Cypripedium Esou giganteum* in splendid condition, the large and beautifully-marked flower being of fine substance; *C. insigne* *Laura*, a heavily-blotched and brightly-coloured form; *C. Minnie*, a charming flower with the large white dorsal sepal spotted with rose; *C. Niobe-Leeannum*, which is good in colour and size; *C. tonsum*, Westfield variety, and *C. callosum* *giganteum*.

Messrs. SANDER & SONS, St. Albans, showed three fine plants of their best strain of *Vanda Sanderiana* with very fine flowers.

Messrs. JAS. CYPHER & SON, Cheltenham, were awarded a Silver Banksian Medal for an excellent group in which good forms of *Cypripedium Leeannum*, *C. insigne*, and some of the newer hybrids were represented. *Cypripedium vil-exul* was a finely-formed flower, *C. Charlesianum*, Cypher's variety, a large yellow flower with finely spotted dorsal sepal; *C. Fairrieanum* and a few other species were also included, and the rare white *Dendrobium aequum*, the elegant *D. Ethel*, some *Dendrobium Phalaenopsis*; pretty specimens of the yellow *Masdevallia Hincksiana* varieties of *Laelia anceps*, and others.

Messrs. HUGH LOW & Co., Enfield, staged a group in which *Laelia autumnalis* and *L. a. alba*,

Cypripedium Maudiae, *C. Leeannum* *Clinkaberry-anum*, *C. aureum* *virginale*, the prettily-marked *C. Adrastus* *Mariae*, the greenish-yellow *C. insigne* *Lucianum* with three flowers, *C. i. Sanderæ* five flowers; a good, nearly pure white *Dendrobium Phalaenopsis*, *Warszewiczella velata*, and the finely-shaped and distinct *Cypripedium insigne* "E. J. Seymour."

Messrs. HEATH & SON, Cheltenham, staged a selection of hybrid *Cypripediums* including the true *C. Swinburnei* *magnificum*, *C. Mons. de Curte*, *C. Leeannum*, &c. Also *Cattleya Percivaliana*, and a home-raised hybrid between *Cattleya Harrisoniana* and *C. Walkeriana* and resembling *C. O'Brieniana*.

Messrs. J. W. MOORE, LTD., Rawdon, Leeds, staged a small group of *Cypripediums*, including *Cypripedium Fowlerianum* *magnificum* of good shape and dark colour; *C. Clio giganteum*, *C. Black Empress*, a very dark-coloured flower; *C. Calypso*, *C. Deedmanianum*, &c.

J. GURNEY FOWLER, Esq., Gledbelds, South Woodford (gr. Mr. J. Davis), showed *Cypripedium Ernest Red* (Wm. Matthews × *callosum* *Sanderæ*), a very large flower, broad in all its parts, whitish, tinged with rose, the dorsal sepal having emerald green lines.

R. I. MEASURES, Esq., Camberwell (gr. Mr. Smith), showed the pretty *Pleurothallis punctulata* and some interesting cut spikes of Orchids.

M. MAURICE MERTENS, Mont St. Amand, Ghent, showed *Cypripedium Lathamianum* *Rex*; the greenish-yellow *C. insigne* *Hyeannum* and other hybrids; *Miltonia Bleuana grandiflora*, *Brasso-Cattleya Digbyana-Mendelii*, *Cattleya Trianae* *delicata* and a form with dark rose-coloured lip.

M. JULES HYE DE CROM, Ghent (gr. Mr. Coen), sent *Cypripedium Lathamianum* *imperatum*, a magnificent, large, and finely-formed flower.

Messrs. LINDEN, Brussels, showed two very handsome varieties of *Odontoglossum crispum* raised by crossing fine blotched forms, and of the same class as those illustrated in the *Gardeners' Chronicle*, December 22, pp. 418-9. *O. crispum coloratum*, the larger of the two, had the fine broad-petalled flowers almost entirely of a rich purplish red with white margin and slight white lines dividing the colour; the *O. crispum emarginatum* had rather smaller and darker flowers, and both had the usual yellow and dark-lined *O. crispum* crest.

Mr. H. A. TRACEY, Twickenham, showed *Cypripedium xanthinum* (*Leeannum* × *insigne* *Furzeannum*). A good yellow flower profusely spotted on the dorsal sepal and petals with chocolate colour, the spotting on the lower half of the dorsal sepal being on a pale-green ground.

J. FORSTER ALCOCK, Esq., Exhims, Northchurch, showed *Cypripedium Chapmanii*, Exhims variety, large and densely spotted with purple; and *C. Charlesworthii*, Exhims variety.

REGINALD FARRER, Esq., Clapham, Lancashire, sent *Cypripedium Phædra*, Ingleborough variety.

J. WILSON POTTER, Esq., Elmwood, Croydon, sent a cross between *Laelia cinnabarina* and *L. Jongheana* with a spike of orange-coloured flowers near to *L. Gwennie*.

J. H. CRAVEN, Esq., Beeches, Keighley (gr. Mr. Corney), sent *Cypripedium Helen II.*, Craven's variety (*insigne* *Sanderæ* × *bellatulum album*). Flowers white, spotted with purple. Lip sulphur-yellow.

GURNEY WILSON, Esq., Glenthorne, Haywards Heath, sent *Odontoglossum Rossii* *Wilsoni*, a pretty form with dark, reddish spotting on the sepals.

DE B. CRAWSHAY, Esq., Rosefield, Sevenoaks (gr. Mr. Stables), sent *Odontoglossum crispum* *Poultoni*, finely grown and flowered, the blooms being clear white, blotched with purple.

AWARDS.

FIRST-CLASS CERTIFICATE.

Odontioda Bradshawia × (*Cochlioda Noelsiana* × *Odontoglossum crispum*) from Messrs. CHARLESWORTH & Co., Heaton, Bradford. A truly great acquisition and a fitting companion to the very beautiful *C. Vuylstekeae*. The plant is of neat habit, and bore a spike of thirteen flowers produced like those of *O. crispum*, but of a uniform cinnabar-scarlet, with a slight shade of the white ground colour being traceable beneath the bright surface colour. The seg-

ments are equal; the lip having a yellow crest with a scarlet blotch in front and a similar colour at the apex. The raisers may be congratulated on their success, for few hybrids are of such distinct characters.

AWARDS OF MERIT.

Odontoglossum Alicea (Edwardii $\times$ *crispum* *Harryanum*) from J. GURNEY FOWLER, Esq., Glebelands, South Woodford. A near ally of *O. Thompsonianum* (Edwardii $\times$ *crispum*) illustrated in the *Gardeners' Chronicle*, May 6, p. 285, but lighter in colour, the claret-coloured blotches being broken by rose-coloured lines. The slender, straggling spike bore several flowers, the ground colour being pale lilac, but the greater part of the surface occupied by claret-coloured blotches, crest of lip yellow (see fig. 15, p. 28).

Brasso-Cattleya Pluto (*C. granulosa* $\times$ *B. Digbyana*) from Major G. L. HOLFORD, C.I.E., C.V.O. (gr. Mr. Alexander). A very remarkable hybrid, with much of the form of *C. granulosa*, but amplified and with the front and side lobes of the lip fringed. Sepals and petals pale green. Lip white, with purple lines from the base.

Cattleya Maggie Raphael alba (*Triana alba* $\times$ *Dowiana aurea*) from Major G. L. HOLFORD. A pretty flower with white sepals and petals, and rose-coloured lip with gold lines.

Phaio-Calanthe Colmanii (*Phaius Norman* $\times$ *Calanthe Regnierii Stevensi*) from JEREMIAH COLMAN, Esq., Gatton Park, Reigate (gr. Mr. W. P. Bound). A fine white variety, with some purple lines at the base of the lip, and the most desirable of *Phaio-Calanthes*. The plant opened on January 1, the day on which Mr. Colman's son, Jeremiah Colman, attained the age of twenty-one, and it was named to commemorate the occasion. It was raised at Gatton Park.

Fruit and Vegetable Committee.

Present: G. Bunyard, Esq. (chairman); and Messrs. W. Bates, S. Mortimer, J. Cheal, A. Dean, W. Pope, E. Beckett, H. Parr, R. Lye, G. Kelf, H. J. Wright, A. R. Allan, J. Davis, J. Lyne, G. Reynolds, J. McIndoe, J. Jacques, Chas. Foster, Jas. Vert, O. Thomas, W. Poupert, and A. H. Pearson.

As is usual, several varieties of Apples were presented for awards, and more than one new variety of Potato, but none was adjudged worthy of distinction. A Cultural Commendation was voted a very fine sample of Glou Morceau Pear, shown by Mr. JOHN CROOK, Forde Abbey Gardens, Chard, and, as stated above, an Award of Merit was granted to a Pear, a description of which is given below.

Messrs. H. CANNELL & SONS, Swanley, Kent, showed some remarkably good Apples, in all 110 distinct varieties. They were exceptionally well coloured, and had been well preserved. As is to be expected in a collection of so many kinds, some of the varieties, as Worcester Pearmain, Cellini, &c., were quite out of season, but the best late-keeping kinds were freely represented, a selection of the choicer being Lemon Pippin, Charles Ross, Allington Pippin, Baumann's Red Winter Reinette, and the new King Edward VII. (Silver-Gilt Knightian Medal.)

Messrs. JAMES VEITCH & SONS, LTD., King's Road, Chelsea, showed a collection of about 60 dishes of Apples arranged in a setting of Smilax sprays. The fruits were medium-sized examples, and representative of most of the best kinds now in season, such as Beauty of Kent, Blue Pearmain (a very fine late-keeping Apple), Standard Bearer (a large conical dessert Apple of very promising appearance), Bess Pool, Grange Pearmain, Winter Peach (a fruit of delicate skin), &c. (Silver Knightian Medal.)

Sir WEETMAN PEARSON, Bart., M.P., Pad-dockhurst, Worth, Sussex (gr. Mr. A. B. Wadds), showed 32 dishes of Apples and Pears, and several bunches of Grapes. The Apples were principally choice dessert varieties, and among the Pears we noticed good fruits of Vicar of Winkfield, Glou Morceau, and Doyenné du Comice, the last-named having the appearance of being capable of keeping till a still later date. (Silver Banksian Medal.)

AWARD OF MERIT.

Pear Bickling.—As stated, this variety was sent for naming, but, as it was an unknown variety and of exceptional merit, the committee

gave it this name, and an Award of Merit. It was sent by Mr. WILLIAM ALLAN, Gunton Park Gardens, Norwich, who discovered it about 10 years ago growing in the gardens at Blickling Hall. He described the tree as a strong grower and a heavy cropper, and the fruits of delicious flavour, which opinion was fully confirmed on tasting. The fruits may be described as a late Doyenné du Comice, and the only difference that could be noted between the two varieties is that the one under notice has its stalk set in a distinct cavity. The flesh is white, melting, and juicy, with just a trace of grittiness.

LINNEAN SOCIETY.

DECEMBER 20.—Lieut.-Col. Prain, F.R.S., vice-president, in the chair.

Mr. WILFRED MARK WEBB, F.L.S., exhibited two specimens of albino woodlice, *Oniscus asellus*, Linn. Prof. Poulton enquired whether either specimen had recently moulted, which would account for the absence of colour. Mr. Webb, in reply, was able to state that that was not the case in one, at least, of the specimens shown.

Mr. N. E. BROWN, A.L.S., exhibited a photograph and dried specimens of *Fockea capensis*, Endlicher, a plant of considerable interest on account of its great rarity and its apparently great longevity. It was originally described and figured by N. J. Jacquin, a hundred years ago, in his *Fragmenta Botanica*, p. 31, t. 34. f. 5, as *Cynanchum crispum*, from a plant which had been introduced from South Africa and cultivated in the Imperial Garden at Schönbrunn. In 1838, Endlicher, in his *Iconographia Generum Plantarum*, refigured the plant and generically separated it from *Cynanchum* on account of its remarkable structure. This self-same individual plant (from which both the above-mentioned figures were made) has been in cultivation at Schönbrunn from Jacquin's time until now, and is the only example of the species known, since Dr. A. Zahlbruckner states that all attempts to propagate it have failed, and no collector appears to have refound it, the only dried specimen in existence, so far as known, being the one exhibited. The living plant was exhibited at the Botanical Congress held at Vienna in 1905, and in the report of that congress, p. 77, is a note concerning it, where it is stated that the age of the plant is probably about 150 years. But when Jacquin described the plant 100 years ago he stated that the tuber was about 1 foot long and 6 inches thick; at the present time, from calculations I have made from the photograph of the plant by comparing the length of the largest leaves on the dried specimen with those of the photograph, I find that the tuber is about 7½ inches thick and stands about 12½ inches above the ground. As this small increase in size during 100 years has been obtained under the conditions of cultivation, where the plant would obtain more moisture and be likely to grow more rapidly than in the very dry climate of its natural habitat, it would appear conclusive that its growth is extremely slow, and that the actual age of the individual in question is probably much more than 150 years. Burchell, in a note with a dried specimen of the very closely-allied *F. glabra*, Decaisne, states that the tuber is sometimes as much as 2 feet in diameter, and, if as slow-growing as *F. capensis*, this would imply that the plant must attain an age of several centuries. None of the species of *Fockea* appears to be common, and as the tubers are eaten by the natives and do not appear to produce fruit freely, it is possible that they may be approaching extinction.

Two other interesting plants are *Babiana spathacea*, Ker, and *Eriosphæra Oculus-cati*, Less., which are exhibited further to illustrate how very rare or very local some of the South African plants are, since neither of these two has been collected by any botanical traveller since Thunberg found them in 1774, until these specimens were gathered. The *Eriosphæra* was originally described as *Gnaphalium Oculus-cati*, Linn. f., Suppl. 364, from a specimen collected by Sparman; a specimen of it in Thunberg's herbarium, upon which Lessing founded the genus *Eriosphæra*, is figured by Harvey in his *Thesaurus Capensis*, vol. ii. p. 30, t. 149.

Dr. A. B. RENDLE presented a report on the botanical collections made by Dr. W. A. Cunningham in Lakes Nyasa, Tanganyika, and the

Victoria Nyanza, 1904-5. Dr. Cunningham spent about three weeks on and about Lake Nyasa, nearly nine months at Lake Tanganyika, and less than a fortnight on the West of the Victoria Nyanza. His object was to make as complete a collection as possible of the plants and animals, especially from Lake Tanganyika, with a view to solving the "Tanganyika problem," and of ascertaining whether the fauna and flora of this lake indicate a former marine connection. As illustrated by a good series of specimens laid on the table, the flowering-plants, fern-allies, and Characeæ, numbering about 45 species, were, for the most part, well-known and widely-distributed forms, with others restricted to Tropical or Subtropical Africa, such as *Ottelia*, *Boottia scabra*, and species of *Utricularia*. In no case was there any suggestion of marine conditions, either past or present, in the representatives of the flora.

The plankton and freshwater Algæ, of which an account was given by Mr. G. S. West, yielded remarkably rich results, due partly, no doubt, to the paucity of our previous knowledge of the microscopic flora of these lakes, especially in the case of Tanganyika. Mr. West's list contains about 400 species, a large proportion of which are new, including one new genus of *Palmellaceæ*. A few species from Tanganyika showed a striking affinity with marine forms, indicating that at some period the water of this lake had a considerable degree of salinity. But, as Dr. Cunningham explained, this did not involve a previous marine connection, but might be explained by an increase in saline matter in the water due to the damming of the outlet from the lake. This damming was perhaps a periodical occurrence, since Stanley, 80 years ago, described the lake as with no outlet, while a few years later Mr. Hore, visiting the same spot as Stanley, found the water rushing through the present outlet towards the Congo.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

DECEMBER 23.—**Committee present:** Messrs. Ashworth, Thorp, Sander, Shill, Warburton, Cypher, Ward, Parker, P. Smith, Leemann, and Weathers (hon. sec.). There was a capital display of plants at this meeting. E. ASHWORTH, Esq., Harefield Hall, Wilmslow, Cheshire, staged a charming group of *Cypripediums*, many choice varieties and hybrids being represented. (Silver Gilt Medal.)

A. WARBURTON, Esq., Vine House, Haslingden, Lancs., also contributed a goodly display of plants. A noticeable example in his group was a fine form of *Odontoglossum Uro-Skinneri* called Vine House var.; this received a First Class Certificate. A similar award was granted to *Brasso-Cattleya* $\times$ *Warburtoni*, a beautiful hybrid between *Brassavola Digbyana* $\times$ *Cattleya Schroderæ* var. *alba*. The flower is almost pure white, and intermediate in character between its parents. From the same collection *Cypripedium* $\times$ *Ville de Paris*, C. insigne var. *Sadleri*, and *Cypripedium* $\times$ *Amy Moore* received Awards of Merit.

S. GRATRIX, Esq., Whalley Range, received Awards of Merit for *Cypripedium* $\times$ *General Stossel*, C. insigne var. *Holfordianum* and C. insigne var. "Sheila."

Messrs. KEELING & SONS, Bradford, received an Award of Merit for *Cypripedium* $\times$ *Hector*, a cross between C. *Sallieri* and C. *nitens* magnificentum.

Messrs. CHARLESWORTH & Co., Heaton, Bradford, exhibited a new and interesting hybrid in *Odontioda* $\times$ *heatonense* var. *St. Vincent*. This plant is a cross between *Cochlidia sanguinea* and *Odontoglossum cirrhosum*, and is a pretty addition to the family.

J. H. CRAVEN, Esq., Keighley, Yorks, gained a First Class Certificate for *Cypripedium* $\times$ *Archimedes* var. *eboraicum*, and an Award of Merit for C. *Archimedes*, Craven's var.

Messrs. CYPHER & SONS, Cheltenham, were awarded a Silver Medal for a choice group of plants, in which a fine specimen of *Cypripedium* $\times$ *Leeanum* with 30 blooms was prominent. P. W.

TRADE NOTICE.

R. O. MEYER, LTD.—Mr. Alfred Foppes has retired from the joint management of the London House in order to take up heating work abroad, and Mr. Paul Krebs will act as sole manager of the London department in future.

Obituary.

R. B. CATER.—We regret to have to record the death, in his 75th year, of this gentleman, who was well known in Bath and whose name is familiar to Rosarians and Chrysanthemum growers. Of late years no exhibition in Bath was complete without his groups. He was one of the foundation members of the National Rose Society, and a Rose brought out in 1898 by Messrs. Cooling was named after him. He was President of the Bath branch of the Gardeners' Royal Benevolent Institution and was most active in business matters connected with the city.

JOHN BYERS.—We are informed of the death of this gardener at Harrogate on December 19, 1906. Deceased, who was born at Stokesley, was 85 years of age. He was apprenticed to gardening at Studley Royal, Ripon, then in the possession of Miss Lawrence. As improver he served under his father in the gardens of Sir Joseph Pease at Darlington. After this he held the position of head gardener to Squire Bethell, at Rise, near Beverley; to Mr. Shuster at Sydenham, whose garden occupied the site of the present Crystal Palace, where he remained until the Palace was half built; to the Lord Chancellor of Ireland, Brady, with whom he remained for 14 years, and to Colonel Tennyson, Kiltonan Castle, co. Roscommon, Ireland, with which gentleman he remained for seven years. For the past 27 years Mr. Byers resided at Harrogate. He was a frequent contributor to the columns of the *Gardeners' Chronicle*.

ANSWERS TO CORRESPONDENTS.

BOOKS: Jacobin. We are not aware of any special value attaching to "Every man his own gardener (1784)." We expect a second-hand bookseller would put a very low price upon it.

CATERPILLAR AT ROOTS OF ROSE: J. S. E. The larva of one of the noctuid moths, but not a recognised pest. It was probably introduced in the potting material (turf). In selecting the turf from the stack care should be taken to avoid using that near to the outside of the stack where there may be living roots of grasses, as it is in such places that various insects or their larvæ are found.

CURRENT-BUDS FOR INSPECTION: Miss M. P. R. There is no trace of the Currant-bud mite in the specimens you send us.

DENDROBIUM INFUNDIBULUM: Correspondent. The parts of an Orchid flower are (except in *Cypripedium*) arranged in three's, but it frequently happens that from some cause or other the parts are disposed in alternating pairs as in your flower. It is interesting, but of no special value.

DESIDERATUM BOILER: A. B. We have not had any experience in the working of the Desideratum boiler, and therefore cannot say whether it is an improvement on the Loughborough heating apparatus or not. You do not furnish us with particulars as to the manner in which your boiler and hot-water pipes are fixed, so as to enable us to tell you the cause of its not acting properly, further than that the boiler "bangs off" when stoking a good fire. This noise may be attributed to faulty circulation of the hot water in boiler and pipes, caused through neglect to secure a sufficient rise in boiler and flow-pipes when fixing same in position (see p. 496 in last volume). Faulty stoking may also be responsible for such noises. If a body of fire is kept near to the front of furnace, where cold water enters the boiler with none at the back, as is sometimes the case, bangs will occur in the first part of the boiler as described in your note. Keep the fire well to the back of the furnace, leaving a clear space of about nine inches between the body of fire and the furnace door.

ELMS: J. Cross. In addition to the common English Elm the undermentioned varieties may be included: *Ulmus campestris latifolia variegata*, *U. c. sarniensis* (Jersey), *U. c. antarctica aurea* (U. Rosseelsii), *U. c. Louis Van Houtte*, *U. glabra cornubiensis* (Cornish), *U. g. vegeta* (Huntingdon), *U. montana Dovzei*, and *U. m. fastigiata aurea* (U. Dampieri Wredei).

EMIGRANT TO BRITISH COLUMBIA: A. G. This district is the extreme western portion of Canada. You will obtain all the information

you require from the Canadian Offices, Parliament Street, Whitehall. See the articles on fruit growing in Canada, p. 189 of our issue for September 15, 1906, and December 8, 1906, p. 384.

FLORA OF VENEZUELA: Correspondent. We cannot find that Mr. Rusby has published any separate work on the subject.

GAS-LIQUID FOR TOMATO SOIL: S. G. R. Gas-liquid is not at all the same product as gas-lime, neither in its chemical composition nor in its manurial effects. The chief properties of gas-lime are about 88 per cent. of lime and 28 per cent. of sulphuric acid. Gas-liquid is valued especially for its compounds of ammonia, being the material from which sulphate of ammonia is manufactured. It varies very much in composition, sometimes containing large quantities of valuable material, sometimes only very little. It contains no lime. Gas-liquid is not to be recommended for Tomato soils, because the ammonia would cause the plants to grow much too rank; there would be an over luxuriance of foliage and stem and but little fruitage. Gas-liquid answers very well for moss-infested lawns. In this case it should be diluted with five or six times its weight of water. Also it may be used with the same amount of dilution for gross-feeding leafy plants such as the Cabbage family.

GAS TAR ON HOT-WATER PIPES: Miss M. P. R. You should have coated the pipes with a composition of lamp black and grease, but now the mischief has been done your better plan will be to wait until the fumes pass off. If you remove all the plants, the tar could be burned off by means of a blow-lamp such as is used by painters for removing paint.

LILY OF THE VALLEY DISEASED: J. P. The plants are badly affected with the disease known as *Botrytis galanthina*. You can do nothing but burn the infected stock. Before growing these plants in the same structure again, you must cleanse it and syringe it well with some fungicide such as permanganate of potash (Condy's fluid), or a weak solution of carbolic acid.

NAMES OF FLOWERS, FRUITS AND PLANTS.—We are anxious to oblige correspondents as far as we consistently can, but they must bear in mind that it is no part of our duty to our subscribers to name either flowers or fruits. Such work entails considerable outlay, both of time and money, and cannot be allowed to encroach upon time required for the conduct of the paper. Correspondents should never send more than six plants or fruits at one time; they should be very careful to pack and label them properly, to give every information as to the county the fruits are grown in, and to send ripe, or nearly ripe, specimens which show the character of the variety. By neglecting these precautions correspondents add greatly to our labour, and run the risk of delay and incorrect determinations. *Correspondents not answered in this issue are requested to be so good as to consult the following numbers.* **FRUITS: A. J. C.** 1, Northern Spy; 2, Royal d'Angleterre; 3, French Crab; 4, Catillac.—*A. Price.* Lord Lennox.—*U. PLANT STAGING IN GREENHOUSES: J. H. An open trellis staging is preferable to one that is closed with slates and covered with shingle, inasmuch as the air can circulate more freely amongst the pots, and the woodwork of the stage will not

decay so soon as if it were covered with the slates and shingle. For Fern-growing it is necessary to arrange a staging that will provide a moister base than that afforded by the open trellis. For bedding plants, growing in heated frames, a base made from cinder ashes is most suitable, provided the frame is not so deep as to cause the plants to be thrown too far below the glass, otherwise growth would be weak. A base of cinder ashes is more helpful to the well-doing of the plants than a staging, whether composed of slate or wood.

SCORCHING OF MELONS: J. H. It is an unusual occurrence for Melons in a green state to get scorched by the sun, but more unusual still for them to sustain injury in this way when the fruits are approaching maturity. The cause is due to imperfect ventilation and neglecting to admit sufficient air early on bright, sunny mornings; or you may have closed the houses too early in the afternoon without distributing plenty of moisture in the house at the same time. Admit a little fresh air to the structure in which your Melons are growing when the thermometer registers between 75° and 80° of heat in the morning, afterwards increasing and decreasing the amount then given according to the weather out of doors. An atmospheric temperature of 85° to 90° should be aimed at between the hours of say, 9.30 in the morning until closing time in the afternoon. Closing time may range from 3.30 in the afternoon from April to the end of May, to 4.30 p.m. in July and August, and the temperature may then safely be allowed to run up to 95° or 100° with an abundance of moisture being distributed in the house when the fruits are swelling. If an atmosphere devoid of moisture is allowed to rise to a heat of 90° or 95° in the morning before admitting fresh air to the house, pit, or frame, the fruit, if fully exposed to the sun, is likely to get scorched, more especially should the plants happen to be rather dry at the roots at the time. It is an easy matter to tell when Melons are ripe. The fruits change from a green or light green to a golden or yellowish colour, exhibit cracks round the stems, and throw off a pleasant aroma. When this evidence of maturity is present you may safely cut your Melons. A free circulation of fresh air should be observed when the fruits are ripening that they may develop flavour, and by keeping the fruit for a day or two in a dry cupboard before eating the flavour is further improved. You should read and study our "Fruits under Glass" calendars from week to week.

SOWING ODONTOGLOSSUM SEEDS: W. P. One of the best cultivators of *Odontoglossums* from seeds whose methods we have inspected has obtained the very best results by sowing the seeds on the surface of the material in pots containing imported established *Odontoglossums* and suspending them in the same house. Another cultivator sowed seeds on freshly imported *Odontoglossum crispum* roots, the plants being simply placed in pots and kept firm by crocks and a little sphagnum to hold moisture. By this method he alleged that he obtained assisting micro-organisms. If some seed-pans are prepared with a convex surface over which soft cotton cloth is strained, the seeds being sown on the cloth surface, good results are secured if the material is kept uniformly moist and in an uniformly genial atmosphere.

STRIPED GOOSEBERRY: L. M. The berries figured on p. 280 of our issue for October 20 last were produced on a bush of the variety Warrington, and were coloured red and pale creamy white.

WARTY SWELLINGS ON VINE SHOOTS: Red Breast. The growth, or intumescence, as it is known by scientists, is the result of some injury which sets up an irritation in that particular spot, to which an increased flow of sap is directed for the purpose, presumably, of repairing the damage. It is a common occurrence, and is usually attributed to damage by frost.

RASPBERRIES AND BRAMBLES.

THE character by which botanists distinguish the Raspberries from the Brambles is that in the former the fruit easily be pulled away from the long receptacle, but in the latter it adheres firm and not be separated.

RASPBERRIES—SPECIES.

—*Rubus idæus* is the common well-known European Raspberry. It is spread through Europe in a wild state, and extends through Siberia to Japan. A list of the cultivated forms will be found in *Olson's Dictionary*.

—*R. obtusifolius*, Willdenow; *R. Leesii*, Engstrom; *R. idæus*, var. *anomalus*, Arrh., singular variety or monstrosity of the non Raspberry, with weak, slender stems, few flowers, and three small round leaflets, joined together at the tip of the common petiole. It was first described by Willdenow in 1811. It has been found wild in several localities in Britain, and also in Scandinavia, Denmark and Germany, and, singular to say, it has lately been discovered in the mountains of Vermont. Good figures will be found

in Boswell-Syme's edition of *English Botany*, tab. 443, and in Lange's *Supplement to the Flora Danica*, tab. 133, and of the American plant in *Rhodora* for 1900, tab. 3. Mr. Culverwell's supposed hybrid Raspberry, figured in the *Gardeners' Chronicle*, Vol. XX. (1883), p. 13, Fig. 8, is *R. idæus* var. *rotundifolius* of Babington, intermediate between *obtusifolius* and the typical *idæus*. Focke says that the reason of its sterility is that its ovaries are incompletely closed.

3.—*R. strigosus* of Michaux (*R. pennsylvanicus*, Poir.) is the common wild red Raspberry, of the Eastern United States. It extends in a wild state from Labrador and Newfoundland across the Continent to British Columbia and Alaska, and southward amongst the mountains to New Mexico and North Carolina, reaching an altitude of 5,500 feet. It is closely allied to *R. idæus*, differing in having the stems and petioles densely covered with bristles, which are often tipped with glands, thinner leaves, densely prickly pedicels, and sepals furnished with a few glandular bristles on the back. It is much cultivated in the United States, and Professor Bailey says is now largely replacing *idæus*, on account of its superior productiveness and hardiness. The fruit is a lighter red than in *idæus*, the principal garden forms being the Cuthbert and Hansell Raspberries. It is in the living collection at Kew. It is figured both by Bailey and in Britton and Brown's *Illustrated Flora of North America*.

4.—*R. occidentalis* of Linnæus is the Black Raspberry of the Eastern United States, called also Blackcap Raspberry, Scotchcap and Thimbleberry. It extends in a wild state from Canada and the Great Lakes southward to Georgia and Missouri, ascending to 3,000 feet in the mountains of Virginia, so that it is not so hardy as *R. strigosus*. Its stems are very glaucous, reaching a length of 10 to 12 feet, and finally arching and rooting at the tip, which is never the case with *idæus* and *strigosus*. The stems are rarely bristly; the leaflets are much larger than in the two preceding, white beneath, the flowers form a terminal panicle, the petals are white and the fruit black. It is frequently cultivated in the United States, the principal forms being the Gregg, Ohio, and Hilborn Raspberries. Like the last, it is figured by Bailey and Britton and Brown, and is in the living collection at Kew.

5.—*R. leucodermis* of Douglas, *R. glaucifolius* of Kellogg, is the Black Raspberry of the western side of North America. It extends from Redwood region of California to Oregon, Utah, and British Columbia. It is closely allied to *R. occidentalis*, but the leaves are more coarsely toothed and the prickles stronger and more hooked. It is figured in Regel's *Gartenflora*, tab. 670, and is in the living collection at Kew.

In all these Raspberries the colour of the fruit varies sometimes to pale yellow.

HYBRID RASPBERRIES.

6.—The most important hybrid Raspberry is the purple-caned American Raspberry, *R. neglectus* of Peck, a hybrid between *strigosus* and *occidentalis*. It occurs sometimes in a wild state where the two species grow together. Bailey mentions as its principal cultivated forms the Shaffner, Philadelphia, Gladstone, and probably the Caroline Raspberries. The fruit varies in the different varieties from red and pale yellow to black. It is figured both by Bailey (Shaffner and Caro-

line types), and by Britton and Brown in their *Illustrated Flora of North America*, and is in cultivation at Kew.

7.—*Rubus nobilis* of Regel is a cross between *idæus* and *odoratus*. It is unarmed, with three large broad leaflets, pale green beneath and a crowded panicle of bright red flowers. It is fully described in Regel's *Gartenflora*, in Vol V. (1857), page 86. This also is in the living collection at Kew. Hybrids of *idæus*, both with *strigosus* and *occidentalis*, are enumerated in Vilmorin's catalogue.

HYBRIDS BETWEEN RASPBERRIES AND BRAMBLES.

8.—The principal hybrid between a Raspberry and a Bramble is the *Loganberry*. The Loganberry was raised in 1881 at Santa Cruz, California, by Judge J. H. Logan, after whom it was named. Its parent was a pistillate form of the common Californian *R. vitifolius*, supposed to have been fertilised by pollen from neighbouring *R. idæus*. It was distributed in 1893, after five years' testing, by the California Experiment Station, through the United States and Europe. It is much more of a Bramble than a Raspberry in its habit of growth, foliage, and fruit. A basket of the fruit was exhibited in Vincent Square at the October show. Mr. Charles H. Shinn, in Bailey's *Cyclopædia of American Horticulture*, says that two adjacent plants grown at Berkeley, California, cover 12 square yards, and in 1899 yielded four gallons of fruit. The late Mr. Richard Dean stated in *The Garden* that with generous treatment its stems in the South of England will make a growth of 20 feet in a season.

9.—*The Mayberry* is one of Luther Burbank's recent "creations." It is a hybrid between *strigosus* and *palmaris*, a very distinct Japanese species, with large long-stalked solitary flowers and palmate leaves, like those of a Maple. It is described as having a large yellow edible fruit, ripening in advance of the Strawberry. We know nothing of it in England.

BRAMBLES—SPECIES.

10.—*Rubus laciniatus* of Willdenow (*R. Quintlandii*, Hort.), is well-known in English gardens. It was first described by Willdenow from the Berlin Botanic Garden in 1811. I believe it to be a cut-leaved form of *R. Selmeri* of Lindeberg, a common British Bramble, the *R. affinis* of Babington, but not of Weihe and Nees. The fruit is much larger and more succulent than that of the common Blackberry of the London greengrocers' shops, which is *R. ulmifolius* of Schott, *R. rusticus* of Mercier, *R. laciniatus* is much cultivated in Oregon, California, and the Sandwich Islands. It is figured by Lange in *Flora Danica*, table 2,303, and also by Bailey and in the *Journal of Horticulture* for 1883, p. 531, Fig. 105.

11.—*R. nigrobaccus*, Bailey, is the plant taken by Torrey and Gray as the typical form of *R. villosus* of Aiton, but it is not Aiton's plant. It is the common arching Bramble of the Eastern United States, extending from Canada southward to Florida, and westward to Arkansas. It has arching stems reaching a length of 10 feet, with stout, hooked leaves of the sterile stem with five ovate pointed leaflets, green beneath and the four upper distinctly stalked, lax simple racemes of 10-20 flowers, small ovate sepals and white petals, and moderately large globose succulent black fruit. There are two cultivated

types, according to Bailey, one the long-clustered Blackberries, such as Taylor and Ancient Briton (see Figs. 2,204, 2,205, 2,206 in his *American Cyclopædia of Horticulture*), and variety *sativus*, with fewer flowers (Fig. 2,207), from which spring the Snyder, Kittatinny and Erie Blackberries. There are several closely allied species, such as *R. argutus*, Link, *R. alleghaniensis*, Porter, *R. floridus*, Tratt., *R. Randi*, Bailey, and *R. Enslenii*, Tratt., which no doubt are included in Torrey and Gray's idea of *villosus*. The typical plant is also figured by Britton and Brown, Fig. 1,898, under the name of *villosus*.

12.—*R. nigrobaccus*, Bailey, is the plant including *R. ursinus* C. and S. and *R. macropetalus* Dougl., is the common Bramble of

amongst its garden forms the Aughinbaugh, Skagit Chief, Belle of Washington, and Washington Climbing Blackberry. It is in the living collection at Kew.

HYBRID BRAMBLES.

13.—The most common hybrid Bramble is *R. heterophyllus*, Willd. A cross between *nigrobaccus* and the true *villosus* of Aiton (*R. canadensis* of Torrey and Gray). It occurs both in wild and cultivated forms. Amongst the latter are the Rathbun, Wilson, and Wilson, junior, Blackberries, now well known to English cultivators.

14.—Another of Luther Burbank's "creation" is the Primus Blackberry, a hybrid between *R. vitifolius* and *R. crataegifolius*, Bunge (*R. Wrightii*, A. Gray), a native of

GUNTON PARK.

PLEASANTLY situated in a beautifully wooded park of 1,000 acres in extent, and some 16 miles from Norwich and $4\frac{1}{2}$ from Cromer, stands Gunton Park, the residence of Colonel Harbord.

The mansion is a square building of white bricks in the Italian style, and it was enlarged by Wyatt in 1785. In the year 1882, many of the principal rooms were ruined by fire, and, unfortunately, some have not been repaired since this disaster, many of the inner walls being now thickly covered with *Ampelopsis Veitchii*. From the south front, a magnificent view is obtained of what is known as the south lake, a sheet of water 25 acres in extent, while on the western side an even larger lake is to be seen, the two being connected with a stream.

A vista, known as the Coronation Avenue,

FIG. 19.—FRUITS OF THE PEAR "BLICKLING," WHICH GAINED AN AWARD OF MERIT AT THE R.H.S. MEETING ON JANUARY 8. "A LATE DOYENNE DU COMICE." (See description in last issue, page 31.)

the western side of North America. It is a very variable species, extending from California northward to British Columbia, and eastward to Idaho. It has long, arching or trailing stems, leaves of the fertile shoots green beneath, either simple and deeply, three-lobed (*vitifolius*), or with three distinct leaflets (*ursinus*). The flowers are often imperfect sexually, like a Hautberry Strawberry, few in number and corymbose, like a Dewberry, with long acuminate sepals, white petals, and a large black succulent fruit of many drupels. *R. macropetalus* is a northern mountain form, with large leaves and flowers. It is figured in Hooker's *Flora Boreali-Americana*, tab. 59. This species has been much cultivated in California and elsewhere of late years for the sake of its fruit. Professor Bailey mentions

North China, Manchuria and Japan. *R. crataegifolius* has leaves like a Hawthorn. It is in the living collection at Kew, and is figured in Regel's *Gartenflora*, tabs. 591 and 924. I have not seen this hybrid in England, but it is included in Vilmorin's catalogue.

15.—The Californian Mammoth Blackberry is a hybrid between *vitifolius* and a wild Texan species, probably one of the *nigrobaccus* group. It is said to be the largest Blackberry ever known, with fruit about 2 inches long, and stems 25 to 30 feet long, but that is in California, not England.

In writing this paper, as will be seen, I have been much indebted to Bailey's *Cyclopædia of American Horticulture*, an indispensable repertory of information about that which concerns gardening in the United States. J. G. Baker.

extends fully a mile in a southerly direction; the trees on either side are Oaks, many of very large size. In the same year that the fire occurred, a length of 800 yards was added to this avenue, so that in time it will be a magnificent feature.

The grounds are extensive, and contain many fine specimen trees. The Spanish Chestnut luxuriates, one of a group on the north-west side of the mansion being especially noteworthy. It is 60 feet in height, the diameter of the trunk at 8 feet from the ground being 7 feet. Some fine specimens of Beech and Oak are growing in the park; one of the latter was planted on a mound at the western end of the estate by John Harbord in the year 1760, and although in a healthy condition, it is of a peculiar tortuous growth. A tree known as the Thorpe Oak, situated about a mile from the mansion, is said to be 200 years old. The branchless trunk is 42 feet in height, and 18 feet in circumference.

Many charming grass glades, giving peeps of a landscape and trees beyond, have recently been made. An avenue of *Arundinaria japonica* (etake), 18 feet wide, has, although but recently planted, attained a height of 12 feet.

A terraced flower garden on the south side of the mansion is bright in summer-time with flowering plants and Roses, and at the time of my visit the climbing and Tea varieties of the latter looked especially healthy and clean, without a vestige of mildew. I also noticed a remarkably fine batch of *Montbretias* *George Vison* and *Germania*, the former proving a most useful variety for providing flowers for cutting in quantity.

The glass department is not extensive. The series are old structures, but they give remarkable results. *Gros Maroc* in-arched on Colmar produces annually heavy crops of pearly bunches with large berries of quite good colour for this variety. Exceptionally fine was a crop of *Muscat of Alexandria* Grapes, the bunches being in-arched on *Foster's Seedling*. Mr. van der Merwe, the gardener, is of opinion that when

well, &c., were the picture of health. *Chrysanthemum* plants carrying from three to six buds gave promise of a fine display later on.

Much attention is paid to the culture of hardy fruit. The soil is suitable—a sandy loam—and there are several good walls with various aspects. Pears are a feature at Gunton. A long, southern wall is furnished with handsome trees that at the time of my visit were laden with excellent fruits of such varieties as *Louise Bonne de Jersey*, *Doyenné du Comice*, *Emily d'Heyst*, *Duchesse d'Angoulême*, *Easter Beurré*, *President Barabé*, *Marie Louise*, *Marie Louise d'Uccle*, *Striped Williams*, *Passe Colmar*, and *Winter Nelis*. On a wall with a west aspect trees of *Marguerite Marillat* and *Fondante d'Automne* were finely cropped. *Espalier* trees were almost equally well cropped, such varieties as *Pitmaston Duchess*, *Striped Williams*, and *Brockworth Park* being especially noticeable.

Wall-trained Peaches, in the appearance of their foliage and fruits, did not suggest any difficulty, climatic or otherwise, in obtaining

FOREIGN CORRESPONDENCE.

THE PROVINCE OF MANICA AND SOFALA IN PORTUGUESE EAST AFRICA.

THE Portuguese territory in Africa under the above name is steadily developing, and the settlers are endeavouring to show the residents what can be done within its boundaries. Within the last three years experimental stations have been opened in different parts of the colony, and in them have been planted many introduced economic plants, with a view to their general culture for profit. The Government of the territory "*Companhia de Moçambique*" wish to show the inhabitants what can be done in this rich corner of East Africa. On the coast and lowlands are two experimental stations, the Mambone, Govaro district, and the Chirenda, Chilokane district, respectively. The success of the various introductions at these stations is established. Land is available for the growing of *Cocconut Palms*, cotton and fibre-producing plants. Labour is cheap and abundant, and transport is easy. In the interior are two more stations, and others are about to be opened. In touch with the railway, 61 miles from Beira, one of the Rhodesia cotton companies is developing some 16,000 acres of land for the growing of cotton plants. The land can be tilled by a steam plough. Valleys of rich soil are at the disposal of the practical agriculturist. I have just visited the western side of the territory, where I saw as fine a crop of *Coffea arabica* on four-year-old trees as I ever saw in India or Ceylon. The plants, moreover, were free from the leaf-disease common to this species of coffee. The *Cedra* rubber tree, *Manihot Glaziouii*, grow freely everywhere.

We have the first plantations in South Africa of *Boehmeria nivea*, the Rhea, Ramie, or China Grass. The fibre is now offered in the London market. The stalks grow to a height of from 4 to 5 feet. The area devoted to its culture will be greatly extended.

Ficus elastica, the Assam rubber tree, does well on this east coast and roots readily from cuttings even when they are simply put in the holes in the field, their only requirements as cuttings being shade and plenty of water.

Fig. 20 shows one of our indigenous climbers, *Telfairia pedata*, with only two years' growth. It is growing over *Ficus cordata*, a common native tree. The fruit of *Telfairia pedata* is as large as a football, and greatly resembles an ordinary green gourd. It contains numerous seeds which are very rich in oil, having as much as 30 per cent., of a tallowy substance. The seed is an article of commerce, being exported to the South of Europe. The Kaffirs have an antipathy to cultivating this plant. It is generally found on trees in abandoned gardens. The plants in the foreground are *Agave rigida* var. *sisalina*, and their culture also represents a new industry in these parts. They are in their third year of planting. We are now making our first cutting of leaves, and the fibre—sisal hemp—from them is of excellent quality. It will represent the first of this fibre exported from South Africa. A large demand exists here for the plants. *Furcraea gigantea*; the green Aloe, is also grown as a fibre-yielding plant.

Mango trees (*Mangifera indica*) were first planted here by one of the early Indian traders who came to this coast and opened a garden at a favoured spot, wherein was good soil and plenty of water.

Gossypium barbadense (South Sea Island cotton) is also cultivated. In 1905 we gathered cotton from plants 110 days old, and this cotton realised in the Liverpool market the high price of 9d. per lb.

Other plants cultivated are *Cocconut Palms*,

FIG. 20.—TELFAIRIA PEDATA GROWING OVER FICUS CORDATA IN PORTUGUESE EAST AFRICA. PLANTS IN THE FOREGROUND ARE AGAVE RIGIDA VAR. SISALINA CULTIVATED FOR ITS FIBRE.

variety is worked upon *Foster's Seedling* as such, there is no risk of shanked berries. In bunches seen there was no sign of such disfigurement, and the colour was distinctly good, of that deep pleasing amber tint seen in the very finest bunches. A capital illustration of how to best utilise the back walls of a house was seen: *Black Hamburg* and *Ali-Grapes* were planted against them, and serviceable bunches of well-coloured grapes were produced.

A new Carnation house has been lately built, this is planted on the American principle. In fact, it is a double span-roof structure 12 ft. in height, 40 feet in length, and 30 feet in width, with beds 4 feet in width down the middle, with paths between them. One bed, 6 inches in width, runs round the building next to the sides. The beds are 8 inches apart.

The arrangement of the hot-water pipes proved to be perfect, and they were so placed that air from the front lights must pass over the pipes as it enters the house. The plants chosen varieties as *Enchantress*, *Challenger*, *Maid*, *Reginald Godfrey*, *President Roose-*

satisfactory results. *Hale's Early*, *Waterloo*, *Early Alexander*, *Violette Hative*, *Condor*, *Royal George* and *Alexander Noblesse*, the latter, with *Desse Tardive*, were especially fine on an east wall. The last-named variety is not as much known as its merits deserve. It crops freely, grows to a good size, the fruits are richly coloured, and, above all, their flavour is good.

Apples succeed well in these gardens. The premier place must be given to *Norfolk Beauty*, which had huge crops of very fine fruit, both on the original tree and on quite small two-year-old bushes. Those who do not grow this kitchen Apple would do well to add it to their collection; it is a cross between *Waltham Abbey* and *Warner's King*, having the combined qualities of the two; one tree, four years grafted, had at the time of my visit 36 handsome fruits. Other varieties in bush and standard form were *Tyler's Kernel*, *Seaton House Russet*, *Lady Henniker*, *Stirling Castle*, *Bismarck*, *Ribston Pippin*, *Allington Pippin*, *Royal Jubilee*, *Cox's Orange Pippin*, *Egremont Russet*, *James Grieve*, *Chelmsford Wonder*, *Golden Noble*, and *Horne's Pearmain*. *E. Molyneux*.

the seeds of which were procured from Zanzibar, India, and Ceylon, and the Sweet Cassava, or Manihot (*Manihot aipi*), new to this territory. The roots of this plant form one of the chief food products of Brazil, West Indies, South America, &c. The starch that they contain is turned into tapioca.

At every experimental station we have stock—cattle, pigs, mules, donkeys, goats, and poultry. *J. R. Alexander, Department of Agriculture, Companhia de Moçambique, Beira, S.E. Africa.*

ORCHID NOTES AND GLEANINGS.

ODONTIODA BRADSHAWIÆ ×.

THIS beautiful Orchid (fig. 21) was the feature of last week's meeting of the Royal Horticultural Society, and was distinguished by a First-Class Certificate, bestowed by the Orchid Committee.

FIG. 21.—ODONTIODA BRADSHAWIÆ ×: COLOUR OF FLOWERS CINNABAR-SCARLET, WITH A YELLOW CREST TO THE LIP.

It represents the crossing of two distinct genera—*Cochlidia Noëliana* and *Odontoglossum crispum*, but it is not the first hybrid evolved from these genera, for *Odontioda Vuylstekeæ* ×, which caused such a sensation at the Temple Flower Show of 1904, claims a similar parentage, save that the *Odontoglossum* species was *Pescatorei*, instead of, as in this case, *crispum*. The predominating colour in the segments is a shade of cinnabar-scarlet, with a yellow crest to the lip that is blotched in front with scarlet. The raisers were Messrs. Charlesworth & Co., Bradford.

LES CATTLEYA TRAITE DE CULTURE PRATIQUE.*

UNDER this title Monsieur Leon Duval issues his new Orchid work designed mainly to deal with the cultural details of the members of the genus *Cattleya*, although the botanical standing of the species forming the genus has been well

and carefully attended to, in some cases according to the descriptions given by Professor Alfred Cogniaux in the *Dictionnaire Iconographique des Orchidées*, most of the 34 illustrations being reproductions of the drawings made by M. Goossens for that work. After the preamble dealing with the genus *Cattleya*, the species are enumerated in alphabetical order, the name being followed by an enumeration of the synonyms and the references, the periods of growth, resting and flowering, and the history and the description of the species. Then follow instructions relating to the management of imported specimens of the species; "culture rationnelle," in which the question of growing in pots or baskets, suspended, or on the stage, the temperature, shading, &c., are set forth; and occasionally a recommendation that the plant may be grown in sphagnum-moss and Polypodium fibre. Then follow paragraphs dealing with the peculiarities of the species;

excessively elaborated (which, as the work is cultural, is not a bad fault), some of those most easy to grow having much space devoted to them; for examples, *Cattleya Gaskelliana* takes up five, and *C. labiata autumnalis* nine pages.

The concluding portion of the book—pp. 204 to 222—is taken up with numerous articles relating to the *Cattleya* house, its proportions, construction, heating, ventilation, shading, and every other point likely to be of use to the Orchidist.

The employment of much time, great care on the part of the author and a wonderful knowledge of the subject are evident throughout the whole of this useful work.

THE ROSARY.

ROSES IN POTS.

THERE are several methods by which Roses may be grown and successfully flowered in pots, and most of these are generally well known. The following is a description of a lesser-known system which I have practised with the best results.

The present is a suitable time to commence operations, and all sections of Roses may be successfully treated under the system detailed below.

Carefully lift the seedling briar, Manetti or de la Grifferaie stocks, as the case may be, that were budded during the months of July, August, and early September, but first subject them to a careful examination to ascertain if the buds are alive and plump. Carefully cut back the longer roots, and trim those which have been damaged in lifting, before potting them in a compost composed of two parts good loam, one part leaf-mould, and one part cow manure—the last-named material to be well rotted and capable of being rubbed through a half-inch mesh sieve. Add a little sharp sand. The whole of these materials must be well mixed together, and in the case of soil intended for strong-growing varieties and climbers, the addition of a 5-inch potful of bone-meal to each barrow load of the potting medium will be very useful. Previous to potting the plants, the stock above the dormant bud should be cut off to within an inch of the inserted bud the remaining portion left above the bud ca. be removed after the latter has commenced to grow. The stock should never be cut quite close to the bud, for it often happens that several inches of the main shoot will die back after pruning, and the bud perishes with it. The vigour of the variety should be considered when potting; and, owing to the free root action they have had in the open ground, the roots will require compressing a little in order to get them into their pots, which should never be smaller than 5 inches in diameter, whilst for the stronger-growing varieties pots 8 to 10 inches in diameter must be used.

Firm potting is particularly necessary, and the soil should therefore be rammed freely. One important item is to have the bud in a line with the soil level, but it must on no account be buried below the surface. After potting, the plants can be placed in a cold frame, or stood in the open air and covered with straw, as this will protect the pots and buds from hard weather, and induce root action. In the case of the more tender Tea varieties, a frame should certainly be used for their protection, as much to guard against excessive damp as from severe weather. The subsequent treatment of the plants from this time will depend upon the available space the cultivator has at his command. If flowers are required a month or six weeks earlier than those in the open, the plants, after having been potted for about one month, should be placed in slight heat, which should be gradually increased as growth proceeds. A little ventilation should be afforded on all

* Les Cattleya Traité de culture pratique. Leon Duval. Paris. Octave Doin, Editeur, 8, Place de l'Odéon. 1907.

favourable occasions, and a slight syringing of tepid water be given overhead when closing the house; as the season advances, and the sun's rays increase in power, two syringings each day will be necessary. Precautions must be taken to guard against mildew, which must be immediately checked by an application of flowers of sulphur, or sulphide of potassium, the latter used at the rate of half an ounce in one gallon of water, and sprayed on the plants towards evening time. As growth proceeds, and the pots become full of roots, the plants should receive a little manurial stimulant. After the plants have flowered, say about the end of April or May, turn them out into a cool frame, to gradually harden off, previous to their being placed in the open air. These old plants are excellent subjects for forcing the following autumn or spring, but a sunny position must be given them that their growths may be perfectly ripened during the summer months.

It will at once be seen that by this system of Rose-growing considerable time is saved, for if the plants were potted up in the autumn, as is generally practised, they require a season's growth before they are properly established, and much time must therefore elapse before they can be successfully forced.

Many of the new rambling Roses respond well to this method of culture, and often produce growths 7 to 8 feet in length the first season after they are potted, and the following spring they flower profusely along almost the whole length of their growth. With me, the variety *Maréchal Niel* (worked upon the *Griffariae* stock) has flowered well in five months from the time of potting the stock containing the dormant bud.

In cold, wet districts, many of the weak and tender kinds of Roses may be lifted and treated in this manner, and after some growth has been made and when the spring frosts are over, be planted out in the open ground. To the grower with limited area and means, this practice is helpful in allowing many of the tender and more beautiful sorts to be successfully cultivated. *W. H. Clarke, Aston Rowant, Oxon.*

FLORISTS' FLOWERS.

PECULIARITIES IN CHRYSANTHEMUM SPORTS.

WITH reference to a parti-coloured or bi-color Chrysanthemum, see p. 435, I may state that this is quite a common occurrence when sporting takes place in these plants. Often it is caused by the flower reverting to its original form, and it is of quite common occurrence in the sports from *Empress of India*, *Golden Empress*, and *Queen of England*. *Waban*, a variety of American origin, introduced into this country some 12 or 15 years ago, was a wide flower, with handsome florets that recurved gracefully at their tips, but it was found to be too "thin" for exhibition purposes, and it did not long enjoy popular favour. The colour, however, was distinctly pleasing, being a rich rose tint, with a plum-coloured suffusion.

These parti-coloured sports are of no garden value, but they show how little control we have over a plant's sporting proclivities. In spite of all scientific knowledge, we are still far away from the power of controlling this phenomenon; in fact, we do not even know the cause of sporting. Among the Incurved flowers more sports have occurred than in the Japanese type, in spite of an excess of varieties in the latter section. Why this should be is difficult to say, and also why so few sports of value are obtained in the present day, as compared with those of 15 years past. Seldom do we find one section sporting to an opposite type, although there are a few of such instances on record. The Incurved *George Glenny* produced a most beautiful Reflexed flower, which Mr. H. Cannell introduced into commerce, and which

was immensely popular for many years and may be now in many places for aught I know. I quite forget its name, but in growth it was stronger than its parent, and it produced flowers freely, and of that delightful primrose colour which rendered its parent so popular.

Another instance of cross-sporting is Mrs. J. Bradney, an Incurved variety obtained from the Reflexed Mrs. Forsythe. This, too, retained its parental colour, and in the neighbourhood of Bristol it was very popular, being especially well cultivated by Mr. J. Bradner, who was a skilful specimen plant producer.

SINGLE-FLOWERED CHRYSANTHEMUMS.

ONLY a few years since it was quite exceptional to find a class at any of the autumn shows for single-flowered Chrysanthemums, but now it would be difficult to name a Chrysanthemum schedule which does not contain one or more classes. Varieties can be raised so freely from seed that an annual revision of lists seems an absolute necessity to maintain an up-to-date collection. The following 24 sorts will supply a thoroughly representative selection:—

Miss Mary Anderson, blush white.
Miss Annie Holden, a yellow sport from Miss M. Anderson.
Edith Pagram, rich pink.
Framfield Beauty, rich crimson.
Earlwood Beauty, primrose shade of yellow.
Purity, white.
Bronze Pagram, bronze.
Mr. R. M. Parkinson, bright yellow.
Earlwood Glory, pure white.
Ewan Cameron, blush white.
Clibrans' Yellow.
Mrs. E. Roberts, blush-tinted.
Mary Richardson, reddish-salmon.
Sir George Bullough, deep yellow.
Eureka, white.
G. W. Forbes, crimson-amaranth.
Victoria, primrose.
Will Jordan, crimson-lake.
Felix, crimson, bronze.
Clibrans' 20th Century, golden shade of bronze.
Elsie Neville, terra-cotta shade of red.
Crown Jewel, bronze-yellow.
King of Siam, deep crimson.
Mrs. Langtry, pink. *E. M.*

VEGETABLES.

CELERIAC AS A WINTER VEGETABLE.

IN this country the Turnip-rooted Celery or Celeriac is not largely grown, yet it forms an excellent winter vegetable, is of agreeable flavour, and, being easily digested, is especially suitable for invalids. On the Continent it is much prized, both as a salad and as a cooked vegetable. Considerable quantities of the roots are imported into this country, but Celeriac can be grown equally well at home as abroad. It does not require to be planted in trenches, but simply in deeply-dug land, and it must be given liberal quantities of food in the shape of fertilisers or liquid manures. Of late years Celery has been much used as a boiled vegetable, but Celeriac is better for the purpose, and this latter plant is the hardier, and can be had in use for six months—from October till the end of March. In the southern parts of this country it can remain in the ground all the winter, providing a little soil be drawn around the crowns; but where the land is heavy, or in cold districts, it should be lifted in the early autumn and be stored in a cool store, from which frost can be excluded, a little soil or fine ashes being placed over the roots to prevent them from shrivelling. The cultural requirements of the plant are simple and very similar to those of Early Celery. The seed should be sown in February or March in a frame or warm house, and when the seedlings are large enough they should

be transplanted a few inches apart, either in frames or in boxes. When sufficiently hardy, they should be planted in their permanent quarters in deep drills drawn 2 feet apart in land that has been well manured. Allow a space of 1 foot between the plants in the rows. At the time of planting, remove all lateral shoots, and when planting is finished give a copious watering. At no time during its growth should Celeriac be allowed to become dry at its roots, and as growth increases afford a liberal supply of soot, and occasionally a little salt. Celeriac is usually ready for planting in its permanent quarters in May and June—the earlier the better—in order that the plant may have a long season for growth. All lateral shoots must be removed, and only the main growth encouraged. There are some fine Continental varieties. The Apple-shaped and the Dwarf Erfurt are both excellent kinds. As to the cooking. Many persons cook it similarly to Beetroot, and when cold slice and place it in vinegar, but I would advise a trial thus: slice goodly-sized roots and fry the rings in butter or in rich stock till they are quite brown, and then serve very hot on toast. Celeriac also forms an excellent dish when made into a purée, and placed around cutlets of any kind. An ordinary form of cooking is to boil it till soft in water, with plenty of salt, and then to serve it with gravy. It may also be boiled like Celery, and served with white sauce. *G. Wythes.*

FRUIT REGISTER.

LATE PEARS.

GOOD varieties of late Pears, such as are in season in March, are not numerous. In October there is an abundance of excellent varieties, which all ripen about the same time. In these gardens the best kinds ripening in October are *Doyenné du Comice*, *Marie Louise*, *Pitmaston Duchess*, *Beurré Bosc*, *Beurré Superfin*, and *Durondeau*. Following later are *Winter Nelis*, a very nice Pear, but small; *Conference*, *Glou Morceau*, *Nouvelle Fulvie*, *Passe-Crassane* (up to the present this last-named kind has with me not been very satisfactory), *Josephine de Malines*, *Olivier de Serres*, and *Zephirin Gregoire*. One of the best of the above named, and one which I intend to plant largely, is *Nouvelle Fulvie*. Fruits of this variety grown on upright cordons assume a bright red colour on the side next the sun and grow to a large size. The flesh and flavour are both excellent in quality. *Josephine de Malines* is also an excellent variety, but in these gardens the fruits this year ripened very early. In some seasons I have kept them in good condition till February. *Glou Morceau* is very good about Christmas time. I am planting this season *Le Lectier*, *Mme. Lye Baltet*, *Marie Benoist*, and *President Barabé*, all late varieties, and these will be given good positions, and be planted in a good sweet loam, to which has been added some burnt earth, a little sweet, well-decayed manure, and a sprinkling of bones and old mortar. Very careful attention in the matters of thinning, feeding, and watering are necessary in the culture of late varieties of Pears, and the fruits should not be gathered till very late in the season. *Beurré Rance* is a variety that keeps well. The fruits are of a desirable size, but the flesh is watery, and I have, in consequence, discontinued growing it. With some growers, I believe it develops very fair flavour and quality generally. It would be interesting if growers would record their experience with respect to the best varieties of Pears for keeping up a good supply during the three first months in the year. It has often occurred to me that stewing Pears might be more largely grown, seeing that the demand for them is on the increase. *Verulam* and *Catillac* (which keeps well) are two good varieties of stewing Pears. *H. Markham, Wrotham Park, Barnet.*

COLONIAL CORRESPONDENCE.

ROSE CLAIRE JACQUIER.

I AM posting you by this mail two photographs of a good Rambling Rose, Claire Jacquier, growing on the house side in this garden. I have measured the plant to-day, and it is 22 feet 10 inches in height and 35 feet in breadth. This was planted nine years ago, and although our soil is all sand it has reached the top of the two-storey house and is now producing more young growths—10 and 12 feet shoots. I think I shall not have much trouble to get it 50 feet in width next season. The only fault this variety has is its short-flowering habit, but it forms a grand wind-break and shade for the stoop plants, of which Begonia corallina over the front door is doing well, covering the wall 11 feet high and as far in width; also President Carnot, with its grand trusses of flower. I shall plant Dorothy Perkins and Lady Gay Roses this season. I have seen Dorothy Perkins make shoots 20 feet in length out here in a season. F. C. Syer, gardener to D. K. Petersen, Esq., Glenmore, Kenilworth, nr. Cape Town, S.A., December 5, 1906.

[Unfortunately the photographs are unsuitable for reproduction.—Ed.]

MARKET GARDENING.

QUICK PROPAGATION OF CARNATIONS.

CALLING, on January 4, upon Mr. J. J. Camfferman, Swan Lane Nurseries, Whetstone, N., I saw 4,000 plants of the variety Enchantress being potted into "thumbs." They were well rooted and strong little plants from cuttings put in on December 15, 1906, 21 days previously, including the day of insertion. Apart from this rapid propagation, special note was made of their absolute freedom from "rust" or disease. Other varieties equally clean and good were Mrs. T. W. Lawson, Floriana and White Perfection. The span-roofed house, running from north to south, and measuring 70 feet by 11 feet, is heated with one row of 4-inch pipe all round, and plenty of additional piping under the bed. The cuttings were rooted in very moderate heat and were not covered with frames. Stephen Castle.

The Week's Work.

THE KITCHEN GARDEN.

By WILLIAM HONKSS, Gardener to C. COMBE, Esq., Cobham Park, Surrey.

Carrots and Turnips.—The forcing of these crops should now be commenced. A good supply of stable litter and leaves will be necessary for the purpose of forming hot-beds, mixing these materials well together, in the proportion of five or six parts of leaves to one of litter, which will ensure a more lasting heat than if more litter were used. Sandy loam, with a liberal addition of road scrapings or screenings from the potting shed, is the most suitable soil for the small-rooting early Carrots, such as Inimitable Forcing, Early French Horn, &c., and for such Turnips as Early Snowball, which is a very good variety for forcing, and for sowing on an early border out of doors a little later on.

Mint and Tarragon.—Lift some roots of these and pack them closely together in boxes filled with light soil, which should be stood in a moist atmosphere at a temperature of about 55° until considerable growth has been made, when they should be removed to cooler quarters.

Asparagus beds.—If the Asparagus beds have not already been given a good mulching of well-rotted manure, this should be proceeded with at once, taking advantage of frosty mornings to wheel it on to the ground. The heavy rains which previous experience leads one to expect in February will then wash the constituents of the manure well down to the roots.

Cauliflowers.—If the autumn-sown Cauliflowers are being wintered under hand-lights or in frames, air should be admitted freely whenever the weather is open, in order that the plants may make hardy and sturdy growth, and so be in the best condition for shifting to their positions out of doors at about the end of the month of March.

Jerusalem Artichokes.—The greater part of this crop is generally left in the ground, sufficient being lifted at one time to last for two or three weeks, thus ensuring a supply in the event of the ground becoming frost-bound. The remaining tubers, however, could now be lifted and sorted into two sizes, the smaller ones being used for "seed" purposes. If it is intended to plant them again on the same ground as before, apply a good dressing of dung, digging this deeply into the soil. The sets may be planted immediately, in rows placed at 3 feet apart, and allowing a space of 15 inches between each set in the rows.

Pea sticks.—If these can now be obtained, advantage may be taken of wet weather to prepare the sticks for use, which will save valuable time later on, for as the days get brighter and longer, there will be much important work requiring immediate attention.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir Trevor Lawrence, Bart., Burford, Surrey.

Calanthes.—Deciduous Calanthes of the *C. vestita* and *C. Veitchii* sections as they pass out of flower should be placed for their short season of rest in a cooler house where the atmospheric temperature will not fall below 60°. Raise them well up to the roof-glass, choosing a position where all the sunlight may reach them. Their immediate surroundings should be kept quite dry, and water at the roots wholly discontinued. Plants of the late flowering varieties as *C. Reginerii*, *C. R. Sanderiana*, *C. R. Stevensii*, *C. R. Williamsii*, *C. Bryan*, *C. Wm. Murray*, and the varieties of *C. Turnerii* which have a few flowers open will require occasional light waterings at the roots until the spikes have become fully developed, when water must be entirely withheld. After the spikes have been cut, place the plants in their resting quarters with those already mentioned. The same remarks are applicable to those plants of *C. vestita rubro-oculata gigantea* which are now developing their flower spikes.

Cypripediums.—During the past five or six weeks a considerable number of Cypripediums have been in bloom in the cool intermediate house, and amongst them may be enumerated the following varieties, all of which are well worth adding to any collection. *C. insigne*, *C. i. Sanderæ*, *C. i. Sanderianum*, *C. i. Harefield Hall*, *C. i. Dorothy*, *C. i. Amy Moore*, &c.; also *C. Leeatum*, *C. L. giganteum*, *C. L. Clinkaberryanum*, *C. L. maculosum*, *C. Hera*, *C. H. Euryades*, *C. Adrastus*, *C. Actæus Langleyense*, *C. Alcibiades*, *C. hirsuto-Sallieri*, *C. Sallieri-Hyeatum*, *C. Fairrieanum*, *C. aureum*, and many others. After the flowers have been cut carefully wash the leaves and free them from all scale, insects, and other pests. Restrict the supply of water during the next few weeks, after which time, if any of the plants require repotting, if large unwieldy specimens need breaking up, or if it is desirable to increase the stock of any particular or rare varieties by dividing the plants into separate pieces, the operations should be commenced. Plants which have become pot-bound should be afforded a liberal shift into pots at least two sizes larger than those they are now growing in. The divided pieces should be placed in comparatively small pots until they become well rooted, when they may again be repotted into pots one size larger. Use clean pots, and drain them to about one-third of their depth with broken crocks. Place a thin layer of rough sphagnum-moss over these, and for a compost use lumps of fibrous loam, coarse peat, and chopped sphagnum-moss in equal parts, adding some broken crocks and silver sand, and well mixing the whole together. Pot moderately firmly. Keep the base of the plant and the compost just below the rim of the pot, so as to make the process of watering easy. For the first few weeks after the plants have been repotted afford them only very moderate quantities of water each time the compost becomes dry, but when well rooted into the new soil, abundance of water will be necessary, both at the roots and in the atmosphere. Keep the repotted plants thinly shaded from all strong,

direct sunshine. Lightly spray the plants overhead on warm, sunny days. To make a well-balanced specimen it is a good plan to select strong, well-rooted plants, and, with a sharp knife, to divide the rhizomes of the old growths in several places, leaving the two front growths intact. In course of time these old growths will produce new ones, which generally come up in the centre of the plant, thereby filling any bare spaces which may have been caused through loss of foliage.

PUBLIC PARKS AND GARDENS.

By W. W. PETTIGREW, Superintendent of the Parks and Open Spaces in the City of Cardiff.

Garden Allotments.—The Allotments Act of 1887 was passed with a view to making it easier for the labouring classes—both in town and country—to obtain allotment-gardens of a fair size at reasonable rents. The Act gives urban and rural authorities the power to purchase or lease suitable land inside or outside their districts for the purposes of allotments, always provided they are quite satisfied that it is not possible for the labouring classes to obtain such allotments from private owners at a reasonable rent. A number of towns and rural districts in England and Wales—Scotland and Ireland are excluded—have, I believe, adopted the Act, and others, while not adopting it, have set aside land already in their possession and let it as allotments under exactly the same conditions as if it had been acquired under the Act. The provision of garden-allotments, whether under the Allotments Act or not, is in many ways a very great boon to working men and their families.

Their management.—The management and control of town garden-allotments naturally devolves upon the Parks Department in all towns where such a department exists, hence it is necessary for superintendents to make themselves well acquainted with the working of the Allotments Act. In the first place, before any land is let it is essential to have a number of rules drawn up for the regulation and guidance of the tenants. Before these rules can come into force they must have the sanction of the Local Government Board just in the same way as ordinary park bye-laws. These regulations may be incorporated in an agreement which ought to be entered into and signed by every tenant, but they may also be on a printed form available for distribution among possible tenants. Authorities are permitted to let allotments from any area up to an acre; but, excepting under special circumstances, no person is allowed to rent an allotment exceeding an acre. For obvious reasons the maximum is never reached in town allotments. In this city tenants at one time were allowed to hold 40 perches, then later they were reduced to 20, and now the demand is so great, and the area of land at our disposal so limited, that it has recently been decided to reduce the size of all allotments to 10 perches each.

The abuse of sub-letting.—As local authorities are, very properly, not allowed to purchase or lease land for allotments unless at such a reasonable price that the rents received from the letting will cover all expenses incurred (excepting draining, fencing, and road-making), it stands to reason that in thickly-populated districts, where the value of land is very high, little suitable ground can be obtained. Under these circumstances, in large towns there are always more applicants for allotments than there are plots to dispose of. This fact often gives an opportunity to the unprincipled to abuse their privileges by sub-letting their allotments at enhanced rentals. Sub-letting is quite illegal, but, nevertheless, it appears to be done wherever allotments are sufficiently large to be so dealt with, and the only remedy seems to be to let them in such small plots that no advantage can be gained by a holder dividing his land with another. Greengrocers are sometimes a source of trouble to those in charge of allotments, for although not eligible under the Act, they often contrive, by some means or another, to get possession of a number of plots and hold them in the names of different persons. A piece of garden ground near a town at the low rent usually charged for municipal allotments is a great advantage to people in this business, and it is not to be wondered at that they do their best to secure it in this way.

Compensation to outgoing tenants.—Some authorities, for convenience sake, and to do

away with the bother of dealing with compensation, allow outgoing tenants to find incoming tenants, who are willing, in taking over their plots, to pay the compensation they ask. This is how undesirable persons get hold of the ground. It is a very bad policy to adopt, for although it may save a little inconvenience at the time, it ultimately leads to a great deal of trouble with would-be tenants. I have known respectable working men apply for years to an authority for allotments without success, while others who had not even made formal application obtained them quite easily by taking them direct from outgoing tenants. This is not as it ought to be. The names, with particulars relating to all applicants for allotments, should be entered in a special book kept for the purpose, and all applications should be dealt with in rotation, as vacancies occur in the allotment grounds. The crops and outbuildings should be valued by a competent person, and the incoming tenant made to pay on his valuation in the ordinary way. This is not only the fairest method of dealing with the letting question, but it is the most businesslike, and the one which in the end works best.

Encourage good cultivation.—Although it does not exactly come within the province of the parks department to encourage a high state of cultivation on their allotments, yet—where there is no local society to do this kind of thing—the department would be doing a great service if even unofficially it did something to promote healthy rivalry among its own tenants.

PLANTS UNDER GLASS.

By J. G. WESTON, Gardener to H. J. KING, Esq., Eastwell Park, Kent.

The propagating house.—This should be thoroughly overhauled and cleaned, in order to have everything in readiness, for quite the busiest time of the year in this department is now approaching. If not already done, the present is a good time for putting in cuttings of *Codiaeums* (*Crotons*) and *Cordylines* (*Dracanas*), thus ensuring for them a long season of growth. "Ringing" is probably a better method of propagating these plants, especially if it is desirable to obtain large plants in a short space of time. [*Codiaeums* raised from "ringing" have usually a better furnished base, with longer, more perfectly developed leaves, than those raised from cuttings.—Ed.] If this latter method is adopted, the material used for covering the cut part of stem should be kept in a damp condition to induce the plant to make roots, and when this has taken place, the rooted shoots should be cut off and potted carefully in light, warmed soil. Place these plants in a position where they can be shaded for a few days whilst recovering from the check. Afterwards remove them to a shelf in the lightest part of the house, and re-pot them when more rooting space becomes necessary. *Dracanas* may also be propagated by cutting up the old stems in the same way that vine-eyes are usually treated, placing the pieces thickly together in pans. This is a good method where large quantities are required, and they will make nice plants in the first season. *Acalyphas* make roots from cuttings very easily, and are useful plants, the variety *A. marginata* being especially useful in a small state. Cuttings of *Panicum*, *Fitonias*, *Zebrina pendula* (*Tradescantia*) and *Pilea* should also be put in, as it will soon be necessary to throw the old stock away, being unsightly. Small batches of cuttings should be inserted at intervals throughout the season, young stock being most decorative.

Cinerarias.—Early plants will now be showing flower, but they may be afforded a little weak manure-water, and kept in an atmospheric temperature of 45° to 50°, varying according to the weather, and falling to 40° on cold nights. A hot, dry atmosphere would be very harmful. Fumigate the plants carefully at regular intervals. Later batches in frames may be kept a trifle cooler, admitting air whenever the outside weather permits.

Herbaceous Calceolarias succeed under similar treatment to *Cinerarias*; the plants in either case must not be permitted to suffer from want of water at the roots. Move them into larger pots in February, or later, according to the state of the plants, never allowing them to become pot-bound, as they are rarely capable of growing freely after suffering such a check.

General work.—Overhaul plant houses generally. Wash them inside and out, give a coat of white-washing to the walls, and effect all necessary repairs, that there may be nothing of this work to be done in the spring. Prepare liberal supplies of leaf-soil, peat, and loam in the sheds, having it all picked over ready for use. See that a supply of charcoal, lime rubble, sand, &c., is maintained.

FRUITS UNDER GLASS.

By ALEXANDER KIRK, Gardener to J. THOMPSON PATON, Esq., Norwood, Alloa, Clackmannanshire.

Peaches and Nectarines.—Early houses, where the trees are coming into bloom, should be heated very cautiously, and when the weather is cold let the atmosphere be kept somewhat drier than usual. When the flowers are fully open, pollinate them once daily when the sun is warmest with a camel's-hair brush or hare's tail mounted on a stick. This treatment is specially desirable in cases of shy-setting varieties. Maintain an atmospheric temperature of 50° to 55° at night, and 60° to 65° by day, until the fruit is set. Admit air through the top ventilators only, taking care to prevent cold draughts.

Orchard house trees plunged out of doors should have a net thrown over them to prevent the buds being damaged by birds.

Early Figs.—When ripe Figs are required early in the season, it is best to cultivate trees in pots. Plunge the pots in a bed having a bottom heat of 70° to 75°. The atmospheric temperature of the pit should be kept at 50° or 55°. Keep the atmosphere of the house moist by sprinkling the paths with water daily. Water the plants carefully. Any plants that require a shift into larger pots should have their roots pruned, as Figs must be kept well in check. The compost used for potting should consist of light, calcareous loam, or, if this cannot be obtained, heavier loam should be mixed with lime rubble. Top-dress all the plants with horse-droppings. Prune the trees, and tie any shoots that may require support.

Figs in borders.—If the shoots of these were properly pinched in summer, the trees will require little or no pruning now. Any shoots that are not required may be thinned out to prevent crowding. Wash the stems and branches with soft soap and hot water, especially if red spider or other pest has been troublesome. Wash the woodwork and glass of the houses, and tie all the trees up neatly to the trellis. Next remove the loose surface soil from the borders and top-dress them with fresh loam and lime rubble. Give the border a good soaking with water, and mulch the surface. Keep the house quite cool at present. When new permanent Fig-houses are being erected, remember to see that the rooting space is confined by building partition walls with bricks, and by concreting the bottom of borders. Make up the borders with a compost of light, turfy loam, two parts, and lime rubbish, one part. No manure will be required to be added to the compost. Extra strong wood is undesirable.

THE HARDY FRUIT GARDEN.

By J. MAYNE, Gardener to the Hon. MARK ROLLE, Bicton, East Devon.

Manuring fruit bushes.—The concluding paragraph in last week's calendar referred to the pruning of Gooseberries and Currants. When the prunings have been removed, the annual manuring of the ground may be proceeded with. There is nothing better for this than farm or stable-yard manure. The better condition it is in the less quantity will be required. It should be wheeled on to the quarters during frosty weather, if circumstances permit, but as one cannot always wait for frost, the most it may be possible to do is to choose a dry day for the work. When the ground is in a workable condition, the manure should be forked-in, care being taken not to interfere with the roots more than is avoidable. If caterpillars were very troublesome last spring, it would be well to first remove 2 inches deep of surface soil immediately under each bush, burying this deeply in another part of the garden, replacing with fresh soil before adding the manure.

Raspberry canes may still be planted on heavily-manured, deeply-dug ground, in rows 5 to 6 feet apart from each other, and allowing 18 inches between each cane. The best supports are made with stout posts and strong galvanised straining wire. The

variety *Superlative* is the Raspberry most generally grown, but I learn that it is not a success on all soils, especially that of a retentive nature. *Hornets*, and *Norwich Wonder* are favourites with many gardeners. A few canes of a good autumn-bearing kind should be given a place in all gardens. The new variety, *November Abundance*, is spoken of highly, and two other good sorts are *Belle de Fontenay* and *October Yellow*. Old-established stools, if not already put in order, should have the canes tied in position, allowing a space of 5 inches between each cane. Apply a good mulch of rich manure over the roots when the canes have been regulated. Autumn fruiting varieties require to be cut close to the ground towards the end of the month, and afterwards may be manured in a similar manner.

Strawberry quarters.—It is pretty general to manure the plants in the autumn, but where such was not done, it would be well to lightly fork between the rows before wheeling on any dressing so that its goodness may be washed to the roots of the plants. The variety *Royal Sovereign*, being such a rampant grower, should not be treated too liberally with manure. Those plantations made last August or September will need no manure, providing the ground was well enriched previous to planting. Do not cover the crowns when spreading.

THE FLOWER GARDEN.

By A. C. BARTLETT, Gardener to Mrs. FORD, Pencarrow, Cornwall.

The making of a pergola.—If it is intended to build a pergola, the work should be commenced without delay. The choice of site requires careful consideration. It must be placed in an open situation and away from all large trees. Perhaps the best place is one that leads from one portion of the garden to another, or in the case of small gardens, near the boundary. While on the whole, in this country, its best aspect is north and south, this point must be settled by various considerations. The massive structures, with huge brick or stone pillars supporting thick Oak poles, which are often seen, appear disagreeably artificial, and a pergola composed of light iron rods and wire-work seems wanting in dignity, and is rather too flimsy except when used for a short pergola to be covered chiefly with *Roses*. Objections may also be raised against one composed entirely of poles on the score of its being short-lived. So that all things considered a compromise of the first and last may be recommended, using local stone for the pillars to a height of about 8 feet, and in these may be set stout poles of Oak, Larch or Elm (the latter lasts extremely well even when exposed to wet and dry conditions), and the cross pieces should be of similar material securely fastened. It is recommended that these poles be used plain and not "ornamented" with rustic devices. Eight feet in height and 9 feet in width will be found suitable measurements, as they will allow of a tall person walking without having to continually "bob" beneath the hanging growths, and three persons may comfortably walk abreast. As there will be a deal of drip in wet weather the path should be well drained and somewhat raised above the level of the outside paths. Where room can be afforded, a "finish" to the structure will be given if a border for herbaceous plants be made each side in line with the pillars. In these borders may be planted hardy Lilies and sweet-smelling plants, such as *Lavender*, *Rosemary*, and the scented-leaved *Pelargoniums*.

Suitable plants.—As this is largely a matter for individual taste it is sufficient to indicate the type of plants best adapted for furnishing these structures. *Clematis*, *Wistaria sinensis*, and *Roses* in variety are indispensable, as also are *Honeysuckles*, *Jasmine*, many ornamental foliage Vines—the new *Vitis Henryana* is very pretty—*Actinidia chinensis*, *Polygonum Baldschuanicum*, &c. When planting a new pergola the plants should be of good size so as to cover the structure as much as possible in the first season, and for this purpose many *Tropæolums* and *Nasturtiums* will be found useful.

Calceolarias and Violas.—These plants should now be stopped by pinching the shoots, at the same time clearing out any decayed leaves. After the stopping has been done keep the frames shut for a few days, and should frost be likely to occur give extra covering. When growth has again started ventilate as freely as the condition of the weather will permit. The old-fashioned *Gazania splendens* requires similar culture. It is a capital subject either for the formation of "edging" or a "ground-work," and will withstand several degrees of frost without suffering harm.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

Illustrations.—The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY, JANUARY 19.—Société Française d'Hort. de Londres Annual Dinner at Café Royal, Regent Street, W., at 6.30 p.m.
German Gard. Soc. meet.

TUESDAY, JANUARY 22.—Roy. Hort. Soc. Coms. meet.

WEDNESDAY, JANUARY 23.—Croydon & Dist. Hort. Mutual Imp. Soc. Ann. Dinner.

THURSDAY, JANUARY 24.—Gardeners' Roy. Benevolent Institution Ann. Meet. and Election of Pensioners at Simpson's Restaurant, Strand, London, 2.45 p.m. Friendly Dinner at 6 p.m. Manchester and N. of Eng. Orchid Soc. meet.

FRIDAY, JANUARY 25.—Roy. Bot. Soc. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—38°5'.

ACTUAL TEMPERATURES:—

LONDON.—Wednesday, January 16 (6 p.m.): Max. 49°; Min. 46°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, January 17 (10 a.m.): Bar., 30°6; Temp., 48°; Weather—Overcast.

PROVINCES.—Wednesday, January 16 (6 p.m.): Max. 48° Ireland S.W.; Min. 45° England E. Coast

SALES FOR THE ENSUING WEEK.

MONDAY AND FRIDAY.—Border Plants, Roses, Azaleas, Liliums, &c., at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.

WEDNESDAY.—Perennials, Lilies, Hardy Bulbs and Plants, at 12; 5,000 Roses and Fruit Trees at 1.80 and 4; Palms, Plants, Azaleas, &c., by Protheroe & Morris, at 67 & 68, Cheapside, E.C.

FRIDAY.—Imported and Established Orchids in variety, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

We have before us the "guide to the experiments" conducted at the University Farm at Impington, near Cambridge, and elsewhere. As these experiments deal almost exclusively with agricultural matters, we can only allude to them in general terms, and express our gratification that matters of such supreme importance, both economically and scientifically, are in such competent hands. If it were possible, we should like to see all the results tabulated, not only in the ordinary method, but also (and eventually exclusively) in terms of the metrical system. We look to the universities and colleges to set the example and adopt a rational system of weights, measures, meteorological records, and the like, so that the results may be made easily comparable one with another and with those obtained on the Continent. For a time it would be necessary to employ both systems. The ordinary cultivator could hardly be expected to do this, but our scientific institutions might do so to their own great convenience. The experiments in breeding cereals are so interesting and so suggestive of what might be done in horticultural practice that we cite them in full:—

Experiments in Breeding Cereals.—Experiments are in progress with these crops with the object of breeding new varieties of improved yield and quality. The improvement in both cases is begun by cross-breeding suitable types. With the re-discovery of Mendel's Laws of Inheritance, the possibility of obtaining results by this method have been largely increased. One can now work on definite lines without having to leave much to chance as the older plant breeders had to do. The definite ways in which plant-characters are inherited are illustrated by the results obtained on crossing together the Wheats known as Rough Chaff and Golden Drop. The former has a *white* chaff which is felted or hairy, while in the latter the chaff is smooth and red. The cross-bred plant has felted *red* chaff, the hairiness and the colour being as pronounced as in the parents. If the grain of the cross-bred Wheat is sown the progeny consists of the following four types of individuals:—hairy red, hairy white, smooth red and smooth white chaff. These types occur in the ratio of 9: 3: 3: 1. All four types can be fixed.

Just as in this case it is possible to combine smoothness and whiteness of chaff and so produce a type of Wheat different from either parent, it would appear to be possible to effect combinations of other characters now existing separately in our cultivated Wheats, such characters, for example, as high yield, stiff straw, the power to resist disease, and good baking quality. Efforts are being made to effect such combinations.

When the work was begun in 1901 some two hundred different sorts of Wheat were grown and kept under observation. The majority of these proved useless for general cultivation under our English conditions, but some few were selected as possessing valuable characters to an unusual degree. Thus one Wheat was chosen because it was rust-resisting, a second because it promised to yield well, a third for its good straw, and so on. These selections have been crossed with Wheats which after continuous trials have proved to be of good milling quality, and step by step Wheats approaching the ideal we set out with have been built up.

Complex as the problem is, the results obtained so far indicate that it is well on the way to a satisfactory solution. Small plots of the fixed types believed to possess considerable strength are now being cultivated from which enough grain will be obtained to test in the mill and bakehouse. The best of these will be selected and grown on in quantity for distribution as soon as possible.

The experiments with Barley are conducted on the same lines. Varieties of good malting value as judged by their nitrogen percentage, as well as by the standards of the maltster, are being crossed with high-yielding types with stiff straws. A number of new varieties have resulted and those, after rigorous selection of the best, will be grown on in bulk for testing in the malt-house.

OUR SUPPLEMENTARY ILLUSTRATION OF NEVIUSIA ALABAMENSIS is of special interest as showing that a lovely plant it is when used for forcing purposes. Of the large number of species which are forced into flower in early spring, few present such an attractive appearance and last in full beauty for such a length of time as the plant under notice. It is a very rare, North American plant, being only found in one locality in Alabama, and was sent to the Royal Gardens, Kew, by Prof. SARGENT, some 24 years ago, where it has proved to be perfectly hardy in the open garden. The plant belongs to the Rosaceæ, and is closely allied to the genus *Kerria*, but differs in being devoid of petals. It forms a slender shrub from 3 to 7 feet high, and flowers in the open in the months of May and June. The flowers are pure white, about an inch

in diameter, and are produced in clusters on short axillary growths, which are developed from the ripened wood of the previous year's growth. The feature of the flowers is the numerous long, white stamens, which impart to the plant a pretty "feathery" effect. The leaves are somewhat loosely disposed along the slender branches, and are from 1 to 4 inches long, $\frac{1}{2}$ to $1\frac{1}{2}$ inches broad, ovate or elliptic-ovate, serrate, and of a pale green colour. The plant is of very easy culture, thriving in a warm position in rich loamy soil, and is readily propagated from cuttings or by division. At Kew, with its attendant fogs and smoke, writes Mr. RAFFILL, the plant has never developed its full beauty in the open air, the flowers always presenting a dirty white appearance; but when, some three years ago, it was used as a forcing shrub for early spring effect in the Temperate House, it attracted much attention. An illustration of the flowers [now reproduced] was given in these pages on April 9, 1904, p. 229. It is also figured in the *Botanical Magazine* t. 6, 806.

ROYAL GARDENERS' ORPHAN FUND.—Readers interested in this excellent charity will be pleased to hear that the Lord Mayor, Sir WILLIAM TRELOAR, has kindly consented to preside at the next annual dinner of the Fund, which will take place at DE KEYSER'S Royal Hotel, Victoria Embankment, E.C., on Thursday, May 23rd next.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.—The sixty-seventh annual general meeting of the members and subscribers of this institution will be held at SIMPSON'S, 101, Strand, London, on Thursday, January 24, 1907, at 2.45 p.m., for the purpose of receiving the report of the committee and the accounts of the institution (as audited) for the year 1906; electing officers for the year 1907; and for the election of eighteen pensioners on the funds. The chair will be taken by HARRY J. VEITCH, Esq., F.L.S., V.M.H., treasurer and chairman of the committee, at 2.45 o'clock. The poll will open at 3 o'clock and close at 4 o'clock precisely, after which hour no voting papers can be received. During the year 1906 ELIZABETH NEWMAN, ANNABELLA E. HERRINGTON, EMMA FINCH, MARY ANN DITE, and ELIZABETH HARRIS, widows of pensioners, have been placed on the funds without election in accordance with Rule III., 13. The voting papers have been issued; any subscriber not having received a copy should communicate with the secretary, GEORGE J. INGRAM, at the offices, 175, Victoria Street, Westminster. We are also requested to state that the annual friendly supper of the friends of this institution will take place after the annual general meeting, on Thursday, January 24, 1907, at SIMPSON'S, 101, Strand, London. The chair will be taken at 6 p.m. by EDWARD WHITE, Esq. (Messrs. MILNER, SON, & WHITE), member of committee.

BRITISH GARDENERS' ASSOCIATION.—We are informed that at the last meeting of the Executive Council of this association, held at the R.H.S. Hall, Vincent Square, S.W., on January 8, Mr. E. F. HAWES in the chair, 28 new members were elected, making a total of 988. Reports were received from the delegates to Bath and Richmond, and a large increase in membership is anticipated. The report of the association's solicitor in regard to registration was received, and will be more fully considered at the next meeting. The question of holding a conference in connection with the annual meeting on May 29 was considered, and arrangements will probably be made to hold one on that occasion.

THE HORTICULTURAL DIRECTORY.—This annual, unlike flowers so called, is requisitioned almost daily in the Editor's room from January 1 to December 31 (Sundays and Bank Holidays excepted). We can give no greater proof of its utility. It is published at the *Journal of Horticulture* Office, 12, Mitre Court Chambers, Fleet Street, E.C., at the cost of one shilling.

Photo by C. P. Raffill.

NEVIUSIA ALABAMENSIS, HARDY SHRUB, FLOWERS WHITE.

Temple Press Ltd., Printers, 7-13, Rosebery Avenue, London, E.C.

THE WATER HYACINTH.—Those who feel interest in the singular balloon-like shape of the leaf-stalk and its adaptation to circumstances, those who delight in the beauty of the flowers of *Pontederia crassipes* in the Water-Lily ponds of this country, will experience something of a feeling of revulsion at hearing this attractive plant spoken of as a "noxious pest." A "weed" plant growing where it is not wanted, and in his sense this quaint-looking plant makes itself so objectionable in some localities in Florida and Queensland and parts of Brazil, for

the report before us, "have the most childlike faith in the efficacy of a 'Weeds Act' against weeds of every class," a state of mind arising from imperfect knowledge, and one with which we are not unfamiliar even in this country. "It is noteworthy," says the report, "that after a period of years certain weeds disappear as suddenly as they came," the conditions of growth being unfavourable at a critical period or periods, the result is the disappearance of the "weed." Spraying is not to be recommended in this case, the removal of the plant by me-

NEW SOUTH WALES.—The Year Book of this Colony for 1906 has just been issued. From it it appears that, owing to the abundant rainfall during the year, the prospects have never been brighter nor the outlook more hopeful. The annual contains a mass of information useful not only to residents but also to those desirous of settling in the Colony. The offices of the Agent-General are at 123, Cannon Street, E.C.

THE PRODUCTION OF NEW VARIETIES.—M. BLARINGHEM states in the *Comptes Rendus* for December 31, 1906, that severe mutilations made

FIG. 22.—SPRAY OF NEVIUSIA ALABAMENSIS. (For habit of plant see Supplementary Illustration.)

as well as in parts of New South Wales, that a Commission has been appointed by the New South Wales Government to make inquiries and suggest recommendations. It is feared in tidal rivers where the current is strong and continuous, but in lagoons and sluggish streams it soon makes boat-navigation almost impossible. The plant is not destitute of nutritive value for forage purposes, and is eaten freely by horses, cattle and pigs, a fact to be borne in mind when attempting to eradicate it. "Many worthy people," says

Mr. J. H. MAIDEN, the Government botanist, as well as by an expert chemist and an expert engineer, mechanical means being alone suggested as practicable by the Committee. The Committee recommends that every landowner be compelled, at his own cost, to destroy all the Water Hyacinth on his property and in the creeks, &c., abutting thereon, within say a period of two years from the passing of the Bill. In certain cases assistance may be given from the public funds towards the eradication of the pest. The report is signed by Mr. J. H. MAIDEN, the Government botanist, as well as by an expert chemist and an

expert engineer, at a particular period constitute a very potent means of inducing sudden hereditary and progressive variations. The plant he experimented on was a variety of Maize.

PHOSPHATES FOR ASPARAGUS.—Asparagus shoots are stated to be rich in nitrogen (asparagine), potash and phosphoric acid, but poor in lime and magnesia. As the result of some experiments made by MM. ROUSSEAU & BRIOT, the use of phosphoric manure is indicated. *Comptes Rendus*, Dec. 31, 1906.

AGRICULTURAL EXHIBITION AT NICE.—It is proposed to hold, next March, at Nice, an international exhibition of agricultural, horticultural, and acclimatization products, to be called the *Exposition Internationale de la Côte d'Azur*. In addition to the usual gardening exhibits there will be a section devoted to packing flowers, while Vines and wines are naturally also among the subjects mentioned in the prospectus. Intending exhibitors should communicate at once with the President of the Société Centrale d'Agriculture, 113 Promenade des Anglais, Nice.

THE NORWEGIAN FLORA.—Mr. OVE DAHL has published a new edition of the late Mr. AXEL BLYTT's *Haandbog i Norges Flora*, which may be had from the publisher, M. CAMMERMEYER, of Christiania, or through Messrs. WILLIAMS & NORGATE. The work is a small 8vo. of 780 pages, entirely in Norwegian, except the names of the plants, which, as usual, are in Latin. Moreover, there are 661 illustrations, an index of Latin names, and a similar enumeration of Norwegian appellations, so that nowadays, when so much interest is felt in Norway and things Norwegian, this descriptive list will be useful, especially to those interested in Scottish and Alpine vegetation generally. The common Scotch Pine extends as far north as lat. 70° and the Spruce to 69°.

THE SWEET PEA ANNUAL.—The third edition of this annual, edited by Messrs. HORACE WRIGHT & CHARLES CURTIS, is tangible proof of the enduring popularity of the Sweet Pea and of the success of the Society. The brochure contains some useful articles by specialists in different parts of the world, and includes several portraits and other illustrations. The receipt of the "annual" and of the report and balance-sheet for 1906 of the National Sweet Pea Society again reminds us of the seventh exhibition which is to be held in the Royal Horticultural Hall, Westminster, on July 16. The schedule of prizes is published with the report, and obtainable from the Honorary Secretary, M. C. H. CURTIS, Adelaide Road, Brentford.

A NEW FRUIT FROM URUGUAY.—The last number (No. 9, 1906) of the *Kew Bulletin*, which we are glad to see appears with greater punctuality than was formerly the case, is a very interesting one. It opens with a description of a new fruit from Uruguay, which our cultivators should look after. It is the produce of a new Sapotaceae tree called by Mr. HEMSLEY *Pouteria suavis*. The fruit is described as of the size of an Apricot, yellow and scarlet in colour, and with a fragrance so delicate that it is equalled by no other fruit, whilst the flavour is extremely agreeable. It has already been introduced on the Riviera, and will, we hope, shortly be tried under glass in this country.

PLANT NOMENCLATURE.—In a recent issue we had occasion to mention at some length the international rules for botanical nomenclature adopted by the congress held in Vienna in 1905. The extracts we made were such as concerned horticulturists as well as technical botanists. Many will be glad to know that the entire text has been reprinted from the *Journal of Botany*, and may be had in the form of a pamphlet at the cost of one shilling from Messrs. WEST, NEWMAN & Co., 54, Hatton Garden, E.C. The articles which are of primary significance have their headlines printed in black-faced type, whilst the "recommendations" are in ordinary small caps., with a different plan of numbering. It would be well if those raisers who now make a practice of applying Latin names to their productions, and thus causing unnecessary trouble, would study and act up to the letter of Article 30, which enjoins the use of fancy names in ordinary language as different as possible from the Latin names of species and varieties.

CLIMATE AND VEGETATION.—KOPPEN has divided the climates of the globe under five principal headings and various subsidiary ones. The principal ones are: (1) those characterised by extreme heat (megatherms); (2) dry climates (xerophiles); (3) warm temperate (or mesotherm climate); (4) cool temperates (or microtherms), and (5) climates characterised by extreme cold (hekiostherms). Our own climate is comprised in that division of the microtherm series, characterised by the general presence of the deciduous Oaks. It comprises the whole of Central Europe, Southern Scandinavia, a large part of the basin of the Amour, Northern China and Japan, parts of the Himalaya Mountains, the northern United States, and British Columbia. Speaking generally, the climate of this region is congenial to the Anglo-Saxon race, and plants derived from these districts are in the main likely to be hardy in Britain. Northward of the region of deciduous Oaks is the climate of the Birch, comprising the north of Scandinavia, Russia, Siberia, and Canada. The summers are short, but light and hot; the winters are severe. The population is robust and accustomed to hard labour in order to secure for themselves the products of the soil. In the hekiostherm climate, the conditions are still less favourable to human beings and to the cultivation of the soil. Local conditions—the existence of high mountains, of heavy or light rainfall, and the nature of the soil—must of course be taken into consideration.

MISSOURI BOTANICAL GARDEN.—The seventeenth annual report has been issued. It comprises a brief history of the garden bequeathed by an Englishman, Mr. SHAW, to the city of St. Louis, and especially a report of the work done during the year ending October 10, 1906. It also contains sundry communications, chiefly of botanical interest, amongst them one by Mr. HTs on the experimental production of fasciation in *Oxalis crenata*. In this paper it is stated that high manuring has a tendency to cause the development of this peculiarity, and other instances are given where excessive nutrition has brought about such a condition. Experiments made in the Missouri Garden show that fasciation may be induced in some plants by the following method. When the plant is beginning to show flower, it is kept as dry as possible. The flowering period will be shortened by this means, and the buds near the end of the spike will remain undeveloped. If now the plants are abundantly watered, and manure water be occasionally applied, numerous fasciations will make their appearance. Sudden renewal of growth and increased influx of sap after a period of relative inactivity are, according to this, the causes to which fasciation is to be attributed. The last abnormally hot and dry summer in England, followed as it was by copious rainfall, ought to have been productive of malformations of various kinds, but, so far as our experience goes, they were not by any means unusually frequent.

SOUTH AMERICAN BEECHES.—Mr. BEAN contributes to the last number of the *Kew Bulletin* some remarks on the S. American species of *Fagus*. *F. obliqua* was introduced from Chile by Mr. ELWES, and there is every probability that it will prove hardy in the southern counties of England and Ireland. *F. betuloides* is represented by a fine tree at Pencarrow (Cornwall), where it is described as one of the striking and ornamental of hardy trees. *F. antarctica* var. *uliginosa* is also in cultivation at Kew from seed supplied by Mr. ELWES. The Chilean forests are being rapidly destroyed by axe and fire, a circumstance that renders it more desirable to investigate and cultivate these trees in suitable localities. Some of them furnish valuable timber.

THE JOURNAL OF THE R.H.S.—The December part of the Journal, completing the thirty-first volume (1906), has just been issued under the editorship of Mr. Geo. S. SAUNDERS. Although so belated that a large portion of the matter has been forestalled, yet there are many who will be glad to have the details in connected form; for instance, there are many who will be interested in Mr. SALMON's article on the American Gooseberry-mildew and the need for legislation, and they will read with attention the account by Prof. ERIKSSON of the means taken to combat the mildew in Sweden. The "notes and abstracts" which form so valuable a feature have been more judiciously selected than before, so as to exclude those notes which have no special reference to practical horticulture.

THE PREVENTION OF CORRUPTION ACT.—We have received a copy of a letter from a well-known and highly-respected proprietor to an equally-esteemed firm of nurserymen:—"Lord — begs to call Messrs. SO-AND-SO's attention to the fact that by the Prevention of Corruption Act, 1906, tradesmen are not allowed to give any commission or gratuities to servants. This rule must be strictly observed." In some large establishments, no doubt, the wages of the upper servants will be increased in compensation for the loss of "commissions," but in the case of the smaller gardens it is to be feared that the gardener, already much underpaid, may often find his income reduced. The British Gardeners' Association will doubtless give serious attention to the subject.

"HERBS FROM THE GARDEN ON THE HILL."—Some curiosity has been expressed as to the herbs that were placed on the coffin of the revered Baroness BURDETT-COUTTS. We are informed that they comprised Winter Savory, Sage, Common Thyme, Lemon Thyme, and Rosemary.

TROPICAL CULINARY PLANTS.—In the last number of the *Journal d'Agriculture Tropicale* we find the report of a lecture by M. BOIS, dealing with various plants used for culinary purposes in Indo-China. Among them are the young shoots of the Bamboo (*Bambusa vulgaris* and others), of which the central portions are esteemed as a vegetable either cooked or pickled. The bulb-like extremity of the stem of another grass, *Hydrophyrum latifolium*, is also used. The Chinese Cabbage, or *Po Tsai*, often mentioned in these columns, is also noticed. Among other plants the leaves of which are utilised as food are *Ipomœa reptans*, an aquatic plant, which, as also *Neptunia oleracea*, is used as Spinach is with us. The "Cabbage" or terminal bud of the Areca Palm forms an excellent salad. Various Gourds, the Water Chestnut (*Trapa cochinchinensis*), and the young pods of *Dolichos sinensis*, and of *Psophocarpus tetragonolobus*, are utilised. The seeds of *Phaseolus Mungo* contain a large proportion of nitrogenous matter. They are used by the Siamese under the name of *Gia*. These seeds are allowed to germinate, and the young sprouts are eaten as a delicacy. The Soy Bean, *Glycine hispida*, is also very nutritious, and is largely used in the East prepared in various fashions. Lastly may be mentioned the seeds of *Nelumbium speciosum*.

WINTER SPRAYINGS FOR SCALE.—We are glad to see that the Duke of BEDFORD and Mr. SPENCER PICKERING have issued, as a separate pamphlet, a summary of the Sixth Report of the Woburn Experimental Fruit Farm, on winter sprayings for scale, of which a review was published in our issue for November 24, 1906. The pamphlets can be obtained, post free, at the price of 2½d. each from Messrs. EYRE & SPOTTISWOODE, East Harding Street, Fleet Street, E.C.

GATTON PARK.—Local journals are full of the doings at Gatton Park, Reigate, on the occasion of the coming of age of JEREMIAH COLMAN, the son of the generous owner of the historical estate we have mentioned, and well known to our readers as an enthusiastic cultivator of Orchids. In addition to munificent donations to local charities and entertainments to the children and old folk of the parish, Mr. and Mrs. COLMAN entertained their friends and neighbours in princely style, the decorations of the famous marble hall and other apartments being made by Mr. BOUND. Palms, Calanthes, Sophronitis, Cyrtopodiums, Zygopetalums, and other Orchids mixed in with Asparagus Ferns, Anthurium Andreanum, Moschosma reparium, and other decorative plants were used with excellent effect.

JAMAICA.—The awful catastrophe that overtook the town of Kingston, Jamaica, on Monday last raises apprehension as to the fate of Sir DANIEL MORRIS, Mr. W. FAWCETT, and others of our correspondents who were assembled in conference to promote the agricultural development of the island. Sir DANIEL MORRIS, who has done so much to stimulate West Indian progress, was to have presided at the congress. According to the latest reports none of the visitors except Sir JAMES FERGUSON was killed.

MONUMENT TO COUNT KERCHOVE DE DENTERGHEM.—We have received from M. ALEXIS CALLIER, President, and M. ALBERT CEUTERICK, General Secretary, of the Ghent Société Royale d'Agriculture et de Botanique, the following letter:—"Immediately after the death of our lamented President, the late Count DE KERCHOVE DE DENTERGHEM, his many friends, unanimous in their feelings of admiration and gratitude, decided to erect a monument to his memory. The committee that has been formed with this object includes the most distinguished representatives of Belgian and foreign horticulture. We invite you to contribute to the fund which the committee has opened and to aid in collecting the funds necessary for the erection of this monument. By speech and pen, with indomitable energy, and by the influence of his name, the Count DE KERCHOVE DE DENTERGHEM rendered to scientific and practical horticulture services the remembrance of which should be perpetuated. The Society itself must not forget all that it owes to him. You, sir, can form an opinion of the enormous development that he has effected in our quinquennial exhibitions (*Florales*) and the important works executed under his direction to secure an equal measure of success for future exhibitions worthy of the Society that organises them. As Belgians and citizens of Ghent we have a right to be proud of the reputation which his efforts have earned for our country and for our dear and beautiful city of Ghent, thus firmly establishing the world-wide reputation of our horticultural industry." We are convinced that among the numerous British visitors to the Ghent quinquennials who enjoyed the friendship and hospitality of the Ghent Society and its learned and genial President, there must be many who will be glad to contribute their tribute to the memory of this distinguished horticulturist, and to show their sympathy and gratitude to the great Society over which he presided. Contributions may be sent to Dr. MAXWELL MASTERS, F.R.S., 41, Wellington Street, Covent Garden, W.C.

PHYLOXERA IN KENT.—It is now some time since we have seen any Phylloxera in our houses, but we regret to say that some affected roots were lately sent to us for examination from a vineyard in Kent. "These vines will be destroyed by fire, the borders turned out, mixed with sulphur and burnt, the house thoroughly disinfected and not used for vines again. No one but those actually employed in the work of destruction should be allowed to enter the affected vineyard, and they should be debarred from access to any other house where vines are growing. Drastic and prompt measures of this kind will, we know, suffice to stamp out the disease.

THE AMERICAN GOOSEBERRY-MILDEW.

IN your account of my lecture at the meeting of the Royal Horticultural Society last week you have fully reported Mr. Massee's criticisms and opinions which he gave after the lecture, but you have omitted the replies which I gave. I must ask now for space to repeat here what I said, and I take this opportunity of mentioning that in the future I shall not attempt to deal with statements on this disease made by Mr. Massee in his private capacity.

(1) Mr. Massee stated that since spraying has come into vogue in the States the mildew has been rendered comparatively harmless; my statement that the mildew practically prevents the commercial cultivation of our Gooseberry in the States Mr. Massee characterised as "one of historical interest only, and without meaning at the present day." I need only state that I have received a letter, written a few weeks ago, from Prof. B. T. Galloway, Chief of the Bureau of Plant Industry, U.S. Dept. of Agriculture, with the following information: "Only a few varieties of European Gooseberries are grown in this country commercially, and these have never been

digenous in Russia." Here Mr. Massee is relying on the early opinion held by Prof. Jaczewski: to use his own words, Mr. Massee's statement "must be considered as of historical interest only, and without meaning at the present day." If Mr. Massee will turn to the Report laid before the Seventh International Congress of Agriculture (Rome, vol. ii., p. 412 [1904]), he will see that Prof. A. de Jaczewski—the scientific adviser to the Russian Government, and the only mycologist who has investigated the disease in Russia—has published here the latest evidence. This evidence has caused Prof. Jaczewski to alter his previous opinion, and he now states that he is convinced that the disease has been brought into Russia on Gooseberry plants imported from America. I adhere to my statement that this disease was unknown in Europe until about 1900, when it was imported from America, and that it must be treated as a dangerous, highly infectious disease of which hitherto English growers have had no experience.

(3) In December Mr. Massee stated in the *Evesham Standard* that the mildew "can only thrive in damp climates." Now, in January, Mr. Massee states that it requires "special weather conditions such as were experienced in this country last year," i.e., *very dry weather*. As a mat-

FIG. 23.—AMERICAN MILDEW ON GOOSEBERRY.
A, mildew on berry and leaves; B, winter-spores in ascus $\times 400$; C, winter-capsule (perithegium $\times 180$ and spore threads); D, summer-spores conidia.

important." Thus we see that, notwithstanding the thorough spraying which the American grower employs, it is still only in a few localities that it has been found possible to grow our Gooseberry, and even this applies only to two or three varieties; elsewhere the mildew entirely prohibits their profitable cultivation. Further, there is now the established fact—and Mr. Massee knew this—that the fungicide (liver of sulphur) which has been found to be the most efficacious in the States is being found to be comparatively useless in European countries. It is expressly stated by Prof. Eriksson, as being the experience of growers in Sweden who have tried spraying—and I am told the same is the case in Ireland—that this fungicide fails when applied to our tenderer European varieties; in the first place, it may cause injury to the leaves and fruit; in the second, it fails to destroy the fungus because of the increased virulence of the latter, due to its reaching a new Continent.

(2) Mr. Massee said that my statement that the disease is new to Europe, and introduced from America, is not supported by facts. I rely on the evidence published by Prof. Eriksson and Prof. A. de Jaczewski, and on the information I have myself collected. Mr. Massee does not publish his evidence, only stating that "some European experts consider that the mildew is in-

ter of fact, from the detailed reports sent to me by gardeners in Ireland, which I have published,* describing the weather conditions under which the continued spread of the disease has taken place from 1900 to 1906, and having regard to the rainfall in the fruit-growing districts in England, there is not the slightest reason to expect that the climates of Ireland and of England will prevent the disease from assuming that epidemic proportion which it has already assumed in the dry regions of Sweden and of Prussia.

(4) Mr. Massee said at the meeting that the disease was already "here and there" in this country, and that, consequently, it was too late to talk of keeping it out by legislation. But when I asked Mr. Massee to tell the meeting of any place where it existed except in Worcestershire, he remained silent. Mr. Massee stated, too, as you report, that, "some Gooseberry growers have expressed the opinion that they have known the mildew in this country for many years. These may not be convincing, but they have not been proved to be wrong." Mr. Massee admits that this evidence may not be convincing, yet he is content to give credence to it, without taking pains to test its scientific

* *Journ. Roy. Hort. Soc.*, vols. xxv., xxvi., xxvii., xxix., and last volume.

value. As a matter of fact, I have investigated the two cases to which Mr. Massee referred, and I find that both are unsupported by any scientific evidence.

The Board of Agriculture has at last recognised the serious nature of the danger; they state in their recently-issued circular that "the disease is of a very serious character, and has rendered the culture of Gooseberries unprofitable and practically impossible wherever it has appeared." That is one important step in the right direction. The second important step will be taken when the Board recognises the fact that the mildew is a new epidemic disease lately introduced into Europe, and now for the first time beginning to destroy the Gooseberry in England, and when it impresses on growers the necessity for treating it as such by immediately stamping it out at the cost of the burning of diseased bushes. Let them make the growers realise that unless the outbreaks are dealt with in this way during the next few years, the same devastation will result as when the closely-allied Vine-mildew was introduced into Europe in the same way from America. So long as the Board allow doubt to remain on this point, some growers will certainly be inclined merely to watch the disease or to experiment with it, and then the disease will rapidly increase in England.

Finally, with regard to legislation. I have seen the mildew on recently-imported standard Gooseberries in a nursery, where the surrounding plots of Gooseberry bushes were healthy. Again, I have ascertained the fact that in the district of Worcestershire, where I discovered the disease in commercial plantations, bushes had been imported from the Continent. The disease is steadily increasing its area on the Continent. I can vouch for the fact that in Kent, and also in other fruit-growing counties, a number of growers are now in the habit of importing Gooseberry bushes direct from the Continent. Is it not obvious that a mere warning as to the danger of importing at the present time would either not reach, or would be disregarded by many importers, and that prompt legislation temporarily forbidding importation can alone save the creation of fresh-infected areas in this country?

Mr. Massee misses the point curiously; he says that the disease, from my own statements, "is most abundant in those countries where legislation against diseases is most stringent," that is, in the States. I am not aware that there is any special inter-State law against the disease; and when we remember the fact (when will Mr. Massee recognise this fact, which every other mycologist recognises?) that the American Gooseberry-mildew is a native of the United States, occurring in practically all States on no fewer than twelve wild native species of *Ribes*, this is not in the least surprising. And it does not affect my statement at all that the disease could be kept out of England by legislation.

In conclusion, I wish to state that I must now leave the matter here. I have pointed out to growers the scientific aspects of the case, I have emphasised the present danger, I have given authorities for all my statements. I have repeatedly urged that immediate legislation is necessary to deal with the disease. It depends now to a large extent on growers; do they care to exert themselves to obtain from the Board of Agriculture the necessary protective measures? *E. S. Salmon, Wye College.*

—We are requested to publish the following letter from our veteran mycologist:—"I have been asked to state my views on the discussion at the meeting of the R.H.S. on this subject. I regret that ill-health, combined with the weakness of increasing age, prevented my attendance on the occasion in question. I have very little faith in legislative enactments, but very great faith in persistent and intelligent individual action. My conclusion would be that expressed at the bottom of p. 24 of the last number of the *Chronicle*: 'Watchfulness and prompt and specially combined action on the part of the growers, will do more than any Act of Parliament to keep the American Gooseberry-mildew in check.' *M. C. Cooke.*"

—I am not an expert in recognising this disease, nor have I seen it that I know of in Europe, but I have taken special interest and notice of fruit-growing in two visits to America,

and I think people in this country hardly realise the condition in Canada and United States as to the Gooseberry. Unlike in this country, where Gooseberries are grown plentifully and in almost every garden in America one hardly sees any plants, and they are almost always unthrifty, and I believe I should be right in saying they are hardly ever on sale in shops; it is more like two or three bushes in an occasional garden. If a traveller were to ask why this is, he would be told that the native Gooseberry is but a poor little fruit, and that the European variety does not thrive because it is so susceptible to this mildew. On the trial grounds of agricultural colleges it is quite likely their Gooseberry bushes are sprayed with potassium sulphide; even in these experiment stations the Gooseberry is grown in very limited quantities, and I think very few other people spray, but consider it hopeless to try and grow Gooseberries to do any good.

Whilst speaking of the American Gooseberry, I think it would be well for growers in this country to remember that there is a most serious Plum disease in North America, the "Black-knot," which attacks the stems and twigs, something like the Beefsteak fungus with us, but black, and occurring all over the tree; this attacks the European and American Plums, but not the Japanese. In Nova Scotia there are "Black-knot" inspectors, who warn those growers who neglect to prune it out of their trees to attend to the matter, and if they do not the inspector does it and charges the grower for the time occupied. It may be asked whether the growers approve of this somewhat paternal method; on making enquiry one finds they do agree with the system and support it. *Cecil H. Hooper, Shoreham, Kent, January 12, 1907.*

—A number of scientists appear to regard the introduction and spread of this new pest with perfect composure, if not, indeed, with absolute pleasure, as affording an interesting field for observation and experiment, and, therefore, deprecate any Governmental interference or constraint in the matter. They tell us that there is no need whatever for alarm, as "the resources of science" are fully equal to the occasion, and that all fungoid enemies may be dealt with by means of spraying and other measures, appearing to entirely overlook the immense addition to the expenses of production which these measures will involve. We must also remember that the Gooseberry is par excellence the fruit of the cottage-gardener, giving the largest return in proportion to outlay of any British fruit, and is for this reason his mainstay for eating and culinary purposes during its season. Our up-to-date gardeners, professional or commercial, will no doubt rise to the occasion and do all that can be done under the circumstances, but among allotment and cottage gardeners there will probably not be 5 per cent. possessing means to purchase apparatus and fungicides, coupled with knowledge and skill to apply them. The outlook at present is that the Gooseberry as a cottager's fruit will shortly disappear, and the country will thus be deprived of a cheap and wholesome food product, entailing a financial loss of which few have any conception. I would wish, in conclusion, as a practical man, to ask those who advocate individual in opposition to State-aided effort how, in the present state of the law, they propose to deal with the grower who has diseased bushes and refuses to treat or destroy them? I could name plenty of sturdy "Arcadians" whose ignorance is only equalled by their intense dislike of interference and readiness to resent it, and should be much interested to hear how prompt action is to be secured in their case. *Charles E. Pearson, F.L.S.*

PLANT-NOVELTIES IN 1906.

(Continued from page 27.)

As with the Orchids, so in respect to other plants, most of the new introductions of the past year have been obtained by the exercise of the florist's art. But in glancing over the list of illustrations of new and interesting plants given in the *Gardeners' Chronicle* during 1906, it is clear that a large number of rare species have still to take their place in gardens when the stock of them is sufficiently large to admit of their distribution.

Especially is this the case with the fine new Conifers, and other plants introduced by Mr. E. H. WILSON through Messrs. JAS. VEITCH & SONS from China, many of which are perfectly hardy, and destined to add new features to our garden scenery. Among the plants certificated to Messrs. VEITCH during the past year are *Buddleia asiatica*, *Vitis Henryana*, *V. armata Veitchii*, *Kalanchoe Dyeri*, a pretty greenhouse plant from Nyassa; and *Begonia elatior*, a bright rosy-carmine, semi-double form of their useful section of winter-flowering Begonias.

FERNS.

Mr. H. B. MAY, of Upper Edmonton, takes the lead in new Ferns, having secured awards for *Nephrolepis exaltata superba*, *Davallia elegans Mayi*, *D. solida superba*, and *Polypodium phymatodes corymbosum*.

Messrs. J. HILL & SON, Lower Edmonton, who cultivate many rare species, and whose magnificent group, containing large specimens of *Gleichenias*, formed such a feature at the Temple Show, exhibited several novelties, their *Davallia canariensis elegans* securing an Award of Merit.

Messrs. ROCHFORD, Turnford Hall Nurseries, produced the fine *Nephrolepis Todeaoides*; and Mr. PRICKETT, of Tottenham, the new *N. cordata tessellata*.

HIPPEASTRUMS.

Major G. L. HOLFORD, C.I.E., C.V.O., West-birt, Tetbury (gr. Mr. Chapman), from his magnificent selection shown on April 3 at the Royal Horticultural Society, secured Awards of Merit for *H. Agamemmon*, scarlet with white band; *Brian Boru*, the best crimson self; *Field Marshal*, orange-scarlet; *Margery*, scarlet with white margin and centre; and *Pearl Maiden*, mottled red and white.

Messrs. R. P. KER & SON, Liverpool, whose strain is remarkably fine and distinct, showed a group at the Temple Show and secured Awards for *H. Jasper* and *Madder Rose*, two very handsome varieties.

BEGONIAS.

Begonias have been recruited by varieties from the various specialists, Messrs. BLACKMORE & LANGDON securing Awards for *Begonias Alice*, *Mrs. J. B. Langdon*, *Millicent*, *Purity* and *Miss May Sutton*.

THE NARCISSUS.

deservedly one of the most popular, as it is one of the most beautiful garden flowers, has its already large number added to by N. Mrs. Robert Sydenham (Miss CURRY, Lismore); N. Brillancy (Rev. G. H. ENGLEHEART); and N. The Rising Sun (W. WELCHMAN, Esq.), April 3; the new N. Pearl of Kent, from Mr. G. P. HAYDON, Canterbury; N. Warleyensis (Miss WILLMOTT), and N. odoratus rugulosus maximus (Messrs. BARR & SONS), which gained Awards of Merit, April 17; N. Eoster (Mr. A. M. WILSON), N. Masterpiece (Messrs. BARR & SONS), and N. Princess Ena (Messrs. R. H. BATH, LTD.), similar awards, May 1; at the same meeting Mr. C. G. VAN TUBERGEN, jun., Haarlem, getting awards for the fine *Tulipa Fosteriana* and *T. Greigi alba*. The Midland Daffodil Society, April 25, also gave a First-Class Certificate to *Narcissus Mrs. Ernest Crosfield*, and Awards of Merit to N. Erda, N. Fiona, all three from E. M. CROSFIELD, Esq.; N. Red Ensign (Messrs. J. R. PEARSON & SON), N. Masterpiece (Messrs. BARR & SONS), and N. Eoster, from Mr. A. M. WILSON.

Chrysanthemums, Dahlias, Carnations, Roses, and all the other great decorative classes of florists' flowers have been greatly improved by the various workers, among them specially successful being Mr. J. DOUGLAS and Messrs. CUTBUSH & SONS in Carnations; Messrs. KELWAY & SON, Langport, in Delphiniums, Gladioli, and their other showy specialties; Mr. AMOS PERRY, with *Nymphæas* and hardy perennials; Messrs. WALLACE, of Colchester, with bulbous and other hardy plants; Messrs. WELLS & Co., Merstham,

who are specialising Chrysanthemums and have several new single forms of great decorative merit; Messrs. JOHN WATERER & SONS, Bagshot, with some charming new Rhododendrons; and other specialists with many novelties.

There is still a very large number of very beautiful novelties in the hands of the large seed firms, who would be well advised to show at the Royal Horticultural Society new and pretty annuals and other plants raised from seeds. The catalogues of Messrs. Sutton & Sons, Messrs. Jas. Veitch & Son, Messrs. Carter & Co., Messrs. Cannell & Son, Mr. Robert Sydenham (especially in Sweet Peas), Messrs. Webb & Son, and other great seedsmen are teeming with good novelties and improved strains of leading sections, which would make a fine show if grown for exhibition.

(To be concluded.)

NOVEMBER AND DECEMBER IN MY FLORIDA GARDEN.

(Continued from page 27.)

The day-blooming Jasmine (*Cestrum diurnum*) is represented in my garden by several large bushes. The flowers are white, very fragrant, reminding one of the perfume of *Stephanotis floribunda*. The plants are almost always in bloom, and they form the happy hunting ground of numbers of insects, particularly bees, butterflies, and moths. Another variety of *Cestrum*, one of my favourite shrubs, and apparently a hybrid between *C. nocturnum* and *C. aurantiacum*, presents a fine show near the verandah. The colour of its terminal flowers, which appear in dense clusters, is a dull shade of orange-yellow, and the perfume exhaled by them in the evening is very refined and aromatic. I grew the plant from seed received from Sir Thomas Hanbury, La Mortola, Italy. These *Cestrum*s are great acquisitions in my garden, and the powerful fragrance of the two first-named specimens is wafted by the gentle breezes to quite a distance. *Cestrum aurantiacum*, with yellow flowers, and *C. elegans* and *C. Boudouxi*, the two last named tall-growing, half-climbing plants, with reddish flowers, also flower profusely in November.

CLIMBING PLANTS.

The verandah is ablaze with climbers, *Antigonon leptopus*, the "Rosa montana," being a sheet of the brightest, most vivid rosy-red imaginable. A large specimen of this climber in full bloom is a glorious sight, and one only surpassed by the glowing orange-yellow of the even more rampant *Bignonia venusta*, which is usually in full bloom at Christmas and at the commencement of the New Year. These two climbers are the most showy and conspicuous of their class, and can be seen from a great distance, lighting up the landscape in a most exhilarating manner. Tourists usually exclaim at the exuberant beauty of these plants. *Allamanda Hendersonii* and *A. Schottii*, both bright yellow and in full bloom, are always exquisite. In the halcyon days of midsummer and in sultry weather they are, however, more prominent than later in the season, when they have to compete with not only the *Antigonon*, but the white-flowering *Thunbergia fragrans* and the blue-flowering *Thunbergia grandiflora*, which is a very vigorous grower, with large and beautiful foliage, &c. A more delicate trailer we may notice in the blue *Solanum Seaforthianum*, with fine clusters of sky-blue flowers delicately infused with a peculiar perfume. It is never out of bloom, and its clusters of brilliant red berries add greatly to its charm. The white-flowering *Solanum jasminoides*, the "Potato vine," as people call it here, is also covered with flower-trusses. It is a valuable climber, but it can neither rival the blue species nor the large-flowering *S. Wendlandii*, which, however, only flowers in our summer's blazing heat. All the true *Jasmines* are now more or less covered

with blossoms, filling the air with their redolence. The most showy of them all is the Star Jasmine (*Jasminum gracillimum*), a scentless species, but a most profuse bloomer and a rampant climber. The flowers are pure white, starry in shape, and appear in conspicuous clusters. The Malayan Jasmine (*Trachelospermum jasminoides*) is a spring bloomer, but it flowers usually for a second time in November, its delicious spicy perfume being perceivable wherever large plants grow. It is a fine evergreen vine, with dark green foliage, and one of the noblest climbers among exotic plants, being only outtrivalled in density of growth, fragrance, and brilliancy of bloom, and poetic associations and sentiment by our native Carolina Jessamine (*Gelsemium sempervirens*), which begins to open its first bright yellow trumpet-shaped blossoms a few days after Christmas, when it pervades the air with a delicious wild wood odour. Stumps and trellises are covered with *Thunbergia alata* in many colours, and our native Moon-flower (*Ipomoea Bona-nox*) is frequently used to screen unsightly places and outhouses with its enormous masses of foliage. Though at its best in midsummer, it is still covered with its large, pure white, strongly-scented blossoms. Being a native and a rather coarse grower, it is not planted here as frequently as its beauty and its fragrance entitle it to be. *H. Nehrling, Florida.*

(To be continued.)

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

TAR AS AN INSECTICIDE.—I have recently used for the winter dressing of Vines a mixture of tar and clay, and it is a very cheap insecticide and very effectual, especially in destroying mealy bug. I have used it more or less during 20 years on Vines and Peach trees; also on plants such as *Allamandas*, *Dipladenias*, *Fuchsias* and *Bouvardias*, after pruning. I consider it to be a good all-round insecticide for treating any deciduous plant or plants that can be pruned back. I believe it to be a good remedy for canker in Apple and Pear trees. Many cultivators are afraid of tar, but the reason for this is because they do not know how to mix it, and the right proportions. *John Willis, Upper Lodge, Hollywood, Portishead, near Bristol.* [Kindly state the proportions you use, and whether Stockholm or gas tar?—ED.]

BEGONIA GLOIRE DE LORRAINE.—I grow four varieties of this Begonia here; three have pink flowers and one is white. Although I have seen seed-pods on them previously, I have never troubled about saving them, although this year I did intend to try and raise seeds if any pods were found. Since Mr. Cromwell's notes have been published in these pages I have carefully looked over the plants for seed-pods, and on the two earliest batches, that are quite over and shabby now, I have found 12 to 15 ripe pods, the seeds of which I have already sown. On the dwarf pink variety, which grows about a foot high here, I counted 40 pods on two plants, and other plants of the same variety have 10 or more pods each. I have also counted as many as 12 pods on some plants of the white variety, although some of them have not quite finished flowering. About the other two varieties I cannot say much yet. One, a large-flowered, pink variety, is at its best now, and the other, a more slender grower, but a deeper shade of pink, is a splendid one for suspending. I do not expect to find many pods on them yet, as I find, like *W. N.*, that all the seed-pods are terminals. Not in one instance have I found a seed-pod other than a terminal. Therefore, I do not think anyone will find any pods until the plants have flowered themselves right out. I myself do not think that "atmospheric surroundings" make any difference, for I have some plants hanging up in the stove, a good number of plants on a stage against a back wall of the stove, and some in a small span-roofed house, all carrying seed-pods. I discovered two pods on one of the large-flowering plants. Some of the individual flowers on this variety measure

2 inches in diameter. As Mr. Cromwell says they come with finer blooms from seed, should I succeed in raising some of this large-flowering one from seed, they should be exceptionally fine. I may say all the plants here have been raised from cuttings. *R. Goodbourn, Ankerwyche Gardens, Wraysbury, Bucks.*

I also have discovered numerous seed-pods on some plants of this Begonia, grown under conditions similar to those related by *W. N.* We have plants growing in 6-inch pots, suspended from the roof of a warm greenhouse, and they have been in a somewhat starved condition for some time. In this case, also, all the female blooms are terminals. *C. S., Tyntesfield Gardens, Bristol.*

In 1901 I found a female flower on one of the plants of this Begonia and I fertilised it with a small camel-hair brush. I sowed the seed, which looked more like fine dust, in February, 1902, but only one seedling appeared; I kept it for some time in an atmospheric temperature of 70°. In September I removed it to a cooler house, the heat being 50° to 55°. The plant flowered in a 8½-inch pot. At this stage of growth I took it to a meeting of the Bristol Gardeners' Debating Society. Not being a member at the time no award was given. I potted the plant on into a 5-inch pot and showed it again in the spring of 1908, when the seedling was awarded a special Certificate of Merit. It is a wonderfully free flowerer and produces seed-pods freely. *Chas Wakefield, Elmfield Gardens, Walsbury-on-Trym.* [Our correspondent has sent flowering sprays of an excellent variety, on which a few of the terminal flowers are female, and have set seeds.—ED.]

MEGACARYON ARMENUM (see p. 28).—When in flower this plant has a somewhat imposing appearance. From a large rosette of hoary foliage rises the branching pyramidal inflorescence. In deep soils flower-stems 3 to 4 feet high are produced with numerous characteristic scorpioid racemes of flowers, the preponderating colour of which is pale, purple-tinged rose. At its best *M. armenum* is not a plant to please all tastes, possessing, as it does, an unrefined appearance without the redeeming feature of a decided colour. The seeds, though considerably larger, resemble those of a *Lithospermum* and are exceedingly hard, but it is by no means essential to remove the outer integument as germination is very little accelerated thereby, and there is considerable danger of the kernel being damaged in the process. Besides this easy means of increase, propagation may be effected by cuttings of the thick, semi-woody roots. The young portions should be selected, those about ½ inch in diameter are best, and pieces 3 inches long should be inserted in sandy soil, taking care to retain the thicker part, or that part which was originally nearer to the crown, uppermost. The operation may be performed in early autumn or spring, and watering should be done sparingly until growth commences. Several crowns will be formed, but it is advisable to remove all but one, the strongest, which, in the course of 12 months, will produce a rosette of leaves 1½ to 2 feet across; flowers may be expected in the next or succeeding year. *E. Horton, Neston, Cheshire.*

TULIP TREE.—When I wrote my note about the beautiful (and, to me, unknown) form of the saddle-leaf Tulip tree (see p. 28), found in the old Dutch book, it was after looking at the plate by lamplight, when its colouring seemed to me to be deep rose, but when seen by daylight it appears to be deep orange, and like a beautifully-feathered Tulip. It is figured on the same plate with a flower of a bulbous Tulip to show how much alike they are. When I first looked at it, and before I noticed the saddle-shaped foliage, I thought they were two Tulips. *W. E. Gumbleton.*

EUPHORBIA (POINSETTIA) PULCHERRIMA.—I enclose two bracts of *Euphorbia (Poinsettia) pulcherrima*. Some of the bracts measure 16 and 17 inches across. We grow three to four hundred plants annually. As decorative subjects for the conservatory and for drawing-room decoration we find them most valuable. When cut the stems are placed for a time in boiling water 3 to 4 inches in depth, and they will afterwards last in good condition for two to three weeks in water. *C. E. Martin, The Hoo Gardens, Welwyn.* [The specimens exhibit excellent cultivation.—ED.]

VICTOR HUGO.—On page 11 in a recent issue is a paragraph relating to the greatest Frenchmen, with Pasteur and Victor Hugo as the two most prominent. Had this census of opinion been taken some years back, I have not the slightest doubt that Victor Hugo would have led the way. Perhaps it may interest some of your readers to know that I am in possession of an autograph letter and photograph sent to me by Victor Hugo, when he was an exile at Hauteville House, Guernsey, in May, 1868, and I believe I am the only man in possession of such an autograph from so great a Frenchman, an autograph his then private secretary told me kings and princes would give any money to possess! *Victor Hugo Lucas, Boro' Forester and Gardener, County Boro', Barrow-in-Furness.*

GLAZED POTS FOR THE GROWTH OF PLANTS.

—I remember many years ago that the use of glazed pots for the growth of plants was strongly advocated by many good cultivators, amongst others (if my memory serves me right) Mr. David Thomson. A strong case in favour of the glazed pot was presented, but the prejudice against it in those days was too strong, and the subject has not been discussed much since. But now I find that the glazed flowerpot is again finding favour with many excellent cultivators, and that in a quiet way it is effectively ousting the ordinary porous flowerpots, more especially from that section of the plant-department devoted to the growth of plants for house and conservatory decoration, where cleanliness is of so much importance. I must confess that, in common with most gardeners, I shared the prejudice against the glazed pot, holding the opinion that the non-porosity of the clay in this pot militated against the well-doing of the plant, in so far that it tended to restrict the quantity of air which penetrated the soil, and also that more frequent waterings were necessary (!) by this kind of pot not being so great an absorbent of moisture. However, on visiting, a short time since, the beautiful gardens of Mr. and Mrs. Leopold de Rothschild, at Ascott, Leighton Buzzard, I formed a more favourable opinion of the merits of the glazed pot by the convincing fact there presented of thousands of winter-flowering and foliage plants growing as luxuriantly in these pots as ever I have seen plants grow in ordinary pots. They were pictures of good culture, and included Crotons, Dracænas, Palms, and other fine foliage plants; also Carnations, Begonias, as well as a general collection of winter-flowering plants. Mr. Jennings speaks highly of them, and is increasing his stock. The only serious objection, it seems to me, which can be raised against the extended use of this pot is on the score of cost. They no doubt cost more in the first place, and yet I think this question of cost will be found more apparent than real. It costs more to buy them in the first instance, but when you come to place in the scale against this the facts that no expense in labour has at any time to be expended in washing the pots whilst the plants are in them, and also the damage to valuable plants so frequently resulting from their being shaken about in the process of pot washing, and the longer life of this pot by reason of its being harder baked, and, therefore, less brittle, I am not sure that the scales will not turn in favour of this pot even in the matter of cost. *Owen Thomas.*

INJURY BY RATS AND PHEASANTS.—I have read with interest the several articles which have recently appeared in these columns on this subject, and it may interest other readers to have my experience. With regard to the injury done by rats, I have suffered in the same way as has Mr. Mountford, but, after destroying the whole plantation of Brussels Sprouts, they also destroyed a large plantation of Broccoli, with the exception of one variety, White Sprouting, and then turned their attention to the Drumhead Cabbages, felling many of them. I think my experience with regard to injury by pheasants is unique: they completely "docked" a large plantation of leeks here this winter, leaving only the stems, which, however, were fully developed before being attacked, and are still fit for use, and last spring they scratched up row after row of French Beans in as thorough a manner as rats do Peas, and ate only the radicle of each Bean. Although I have counted as many as 30 pheasants amongst and around the Gunneras, they have in no way injured them. *W. M. Macdonald, The Gardens, Kylemore Castle, Co. Galway.*

VIOLETS IN POTS.—The illustration on p. 27 of the *Gardeners' Chronicle* of Violets flowering in pots is both seasonable and timely, and displays unmistakably the value of the plant when thus grown. Some appear to experience difficulty with the Violet as a pot plant, while growing the plant with success in the open garden and in frames. In my own immediate district, where fog and damp are very general, no mode of treatment is so reliable as the permanent pot-method for insuring flowers during the duldest season of the year. A very old gardener of my acquaintance grew the double-flowered varieties with considerable success for years in 8-inch pots. Personally I prefer to use 8-inch pots. Mr. Stokes has shown, however, that good results can be secured in pots of a lesser size. *E. J.*

LILY OF THE VALLEY.—In your issue of January 5 an article appears entitled Lily of the Valley for small growers, which, although instructive in the main, is, nevertheless, very misleading. One point claimed is that one of the Hamburg exporting firms will sell as small a quantity as 1,000; one firm we know of in England will supply as few as 25 crowns. Again may we quote the following: "As a general rule it is better to avoid samples retarded in England. These are usually frozen in public cold stores with provisions and other goods, and this kind of cold air is unsuited to retarding Lily of the Valley, and according to the writer's experience (which covers handling about two and a half million each of both fresh and retarded crowns), 9 out of 10 batches grown from English retarded crowns are a dismal failure. In Hamburg they are retarded in specially-constructed houses, and one or two firms have made a special study of the work, have their own cold stores, and have brought the business almost to perfection." Now the firm we have in mind have also their own cold stores built entirely for this work, and I am sure they possess the necessary experience, as they have been retarding Lily of the Valley for the last 18 years; in fact, were the pioneers in this country, and now handle annually 10,000,000 crowns. In conclusion, we should like to point out that the majority of the Lily of the Valley crowns retarded in Hamburg are the cheap rubbish which the dealers find a difficulty in disposing of in the autumn, whilst over here in England it is generally the very best quality only that is put away in the refrigerator, and it stands to reason that the better the quality the more able the crown is to stand the long period of retardation. *R. and G. Cuthbert, Southgate, Middlesex.*

ABIES RELIGIOSA (LINDLEY).—It makes a handsome tree and grows freely here, being quite uninjured by frost, although it is spoken of as not hardy in this country (*Nicholson's Dictionary*). Gordon says, "Schiede found it growing upon the cold mountains of Orizaba, at the highest limit of arborescent vegetation," and also "Hartweg found it at an elevation of 9,000 feet." One would imagine that it is quite hardy, but perhaps it is not easy to establish, and this may account for its being so rarely seen. I wonder why *Abies religiosa*, or any of its synonyms, does not appear in *Kew Handlist* of Coniferae. Has this name also been suppressed for a new one? [No.] Speaking of names, the list just referred to holds the specific name insignis and not radiata for the Monterey Pine. The *Kew Handlists* are admirable in their usefulness and cheapness, and many gardeners accept the nomenclature as authoritative, but often finding other authorities upholding different names. *H. W. Trevince.* [The absence of *A. religiosa* from the *Kew Handlist* may be owing to the circumstance that it was not grown in the gardens at the time the list was compiled. There has been much uncertainty about *Pinus insignis*, but we believe that it is now generally considered as specifically identical with the earlier named *radiata*, though there is considerable difference between individual specimens. —Ed.]

SOCIETIES.

ROYAL HORTICULTURAL Scientific Committee.

JANUARY 8.—Present: Mr. G. S. Saunders, F.L.S. (in the chair); Messrs. J. T. Bennett-Poë, E. A. Bowles, E. M. Holmes, and F. J. Chittenden (hon. sec.).

Pleurothallis sp.—Mr. R. A. ROLFE reported that the *Pleurothallis* shown at the meeting on November 20 by R. I. MEASURES, Esq., could

not be identified at Kew, but may be one of several described by Reichenbach still only known from description. It is near *P. velaticaulis*, Reich f.

Grapes shanking.—Some shoots of vines, the fruit of which had shanked, were received from Basingstoke. From the description of the border, that accompanied the specimens it was thought that the trouble was undoubtedly due to unhealthy root action, and that renovation of the border would probably result in improvement in the growth of the fruit.

Magnolias and mealy bug.—Some shoots of *Magnolia* affected with mealy bug were received from Horsham. The shoots were from plants growing on the south side of a wall 200ft. long and 15ft. high, and, although various insecticides had been tried upon the plants, no good results had followed. The scale insects were, curiously enough, not found in the houses built on the south side of the wall. Mr. SAUNDERS reported as follows:—"The mealy bug attacking the *Magnolias* is *Dactylopius longispinus*. Of course, it is very difficult, if not impossible, to properly cleanse the leaves with an insecticide, as the plants are growing against a wall. It might, however, be possible to destroy them with hydrocyanic acid gas if some comparatively airtight covering could be constructed over the plants, e.g., a tarpaulin or a rick cloth might be fastened to the wall in the same manner as the top. The gas is generated by pouring sulphuric acid over cyanide of potassium. The method of procedure is as follows: Place 4 ounces of water in an earthenware jar, pour slowly into it 1½ fluid ounces of sulphuric acid (specific gravity 1.84), then in a shallow earthenware dish put 1 ounce of potassium cyanide (98 per cent. strength), and arrange the jar of acid so that its contents can be slowly poured over the cyanide, without any chance of the fumes reaching the operator, as they are most poisonous. Or the cyanide may be wrapped up in a piece of blotting paper and placed on a piece of board laid on the top of the jar, but not closing the mouth, and by means of a stick or string it may be dropped into the jar containing the acid, and then every aperture tightly closed. The above recipe gives the quantities for use in a space containing 150 cubic feet of air; if the space be larger the quantities must be increased in proportion. The plants should remain exposed to the fumes for above three hours. Means must be devised to remove the covering, or at least to open it, so that all fumes escape without any person breathing them, as they are very deadly. It is curious that the insects do not infest the plants in the houses on the other side of the wall. Mealy bugs do not breed in the ground, but usually on the plants; they may, however, do so at times in cracks, &c., in the walls. They lay their eggs in masses covered with a cotton-like secretion, in convenient positions on the plant.

Plants for naming.—Shoots of *Edwardsia tetraptera*, *Clanthus puniceus*, and another, of which the material was insufficient, were received from Stockton.

Malformed Cyrtopodium.—Dr. MASTERS reported that he had examined the curious *Cyrtopodium* shown at the last meeting by Mr. BENNETT-POË, and found that there were three sepals, two lateral and one anterior, and three petals, one posterior and two lateral. The lip was normal; the column had two staminodes, the stigma was obliquely two lobed, and the axis of the flower was diagonal, the ovary being normal with one cell, and three parietal two-lobed placentæ. The following diagram represents the arrangement of the floral organs:—

Monacious Mistletoe.—Dr. MASTERS showed a specimen of this rarely occurring form on behalf of Mr. CORDEROY, of Didcot, and a variety of the common Mistletoe having thick, leathery leaves about four times larger than usual.

Christmas Roses diseased.—Mrs. SQUAREY, F.R.H.S., sent leaves of the Christmas Rose

which had turned brown and died; the flowers appeared, but rose little above the surface of the soil. Mr. BENNETT-POK said that he had found a similar thing to occur when the roots are attacked, as is frequently the case, by the grubs of the crane fly. Gooseberry shoots, diseased Cucumbers, and Amaryllis bulbs were also received, and will be reported upon at the next meeting.

THE ASSOCIATION OF ECONOMIC BIOLOGISTS.

JANUARY 9, 10, 11.—The annual and fourth general meeting was held in the Pathological Department of the University of Cambridge on the above dates.

The retiring president, Mr. T. V. Theobald, occupied the chair.

The following were elected as officers for 1907:—President: A. E. Shipley, F.R.S. Vice-Presidents: Sir Patrick Manson, F.R.S., Professor William Somerville, and Fred. V. Theobald. Council: Professor G. S. Boulger, W. G. Freeman, Professor Geo. H. Carpenter, Dr. Francis, H. A. Marshall, Robert Newstead, Professor Ronald Ross, F.R.S., Fraser Story, and Cecil Warburton. Hon. treasurer: Herbert Stone. Hon. secretary: Walter E. Collinge.

Mr. A. E. Shipley, F.R.S., the newly-elected president of the association, delivered his presidential address on "Sea Fisheries." Dwelling on the magnitude of the fishing industry in these islands and the arbitrary fluctuations to which sea fisheries are exposed, he sketched the history of legislation on sea fishing during the last 75 years, and pointed out that even now our knowledge of the life histories, the migration, the enemies, and the food of fishes was hardly precise enough to enable us safely to legislate.

Professor Nuttall, F.R.S., made a communication on "Redwater Fever and Allied Diseases."

Mr. Biffen illustrated, by means of a series of lantern slides, the inheritance of the characters lax and dense ears in Wheat, and also beardless and bearded ears, first separately, and then in combination with one another. Following this, inheritance of the characteristics of Wheat and Barley were traced. Included amongst those were such characteristics as "strength" or good baking quality and the power of resisting the attacks of yellow rust in Wheat. The results of his experiments indicate that it is practicable to combine in one variety the excellent quality of certain Canadian Wheats, the vigour of English varieties and immunity to the attacks of rust.

Mr. E. S. Salmon gave an account of the American Gooseberry-mildew, which gave rise to a lengthy discussion, in which Prof. Middleton, Mr. Percival, Prof. Fisher, Prof. Carpenter, and Mr. Walter E. Collinge took part.

Mr. Walter E. Collinge made a contribution to the subject of the extermination of the Black Currant gall mite. He advised no one to be led away by the statements which have appeared in certain horticultural and agricultural journals to the effect that there was no likelihood of a cure for the pest, or even the means whereby the mite could be kept in check. The experiments which he had conducted over seven years had yielded results, checked by many large fruit-growers, which clearly pointed to the fact that applications of lime and sulphur offered an effective remedy, and that if they were continued they would eventually entirely eradicate the pest.

Dr. R. S. MacDougall gave an account of his experiments in regard to the parthenogenesis of the Pine sawfly, an insect which does a great deal of damage to Pine plantations, and Mr. E. V. Theobald read a paper on new hemipterous fruit pests in Britain.

Mr. W. G. Freeman read an important paper on the geographical distribution of the principal Rubber Plants.

The distribution of the principal members was described in detail, and the more important factors limiting the range of the species discussed. Attention was directed to recent work, such as the discovery of *Funtumia elastica* in East Africa and of the important new Rubber Plant, *Landolphia Dawei*.

During the past 80 years much experimental work has been carried out in introducing Hevea, Castilleja, Ficus, Funtumia, and Manihot into other countries. A summary was given of the

chief results obtained, with especial reference to the establishment of the important rubber industries of the Far East, and the prospects of rubber cultivation in the West Indies, tropical Africa, &c. The question of "wild" versus "plantation" rubber was discussed, and an attempt made to indicate the general trend of events.

Mr. E. R. Burdon contributed a paper on the Spruce gall and Larch-blight diseases caused by Chermes. After sketching the life-history, an account was given of the remedial measures that had been found to be effective.

Mr. F. V. Theobald gave an account of certain insect pests in the British East African Protectorate.

An extraordinary disease affecting horses was described by Mr. T. S. P. Strangeways.

The blood changes in man caused by the Metazoan parasites and their aid in diagnosis was the subject of a paper by Mr. E. G. Fearnside.

Mr. W. G. Freeman described the use of an economic museum in the teaching of geography. Collections of botanical products of economic value might be classified in one of three ways, according to (1) botanical origin, (2) geographical origin (3), use, i.e., under food stuffs, fibres, timbers, gums, resins, &c. Specimens, photographs and other illustrations were exhibited to demonstrate that a collection could afford a comprehensive idea of the botanical products and resources of particular countries, with especial reference to Southern Nigeria, Barbadoes, and Dominica, and how such collections might be brought within reach at low cost of schools who had not ready access to economic museums.

DEBATING SOCIETIES.

GROVYDON & DISTRICT HORTICULTURAL.—The annual general meeting of this association was held on Wednesday, January 9. The annual report showed that this society is making good progress. Twenty-one meetings have been held during the past year. The annual dinner, on Wednesday, January 24, was again a success. Nearly 100 members and friends attended, and spent a pleasant evening. The spring flower show was held a little later in the season than in previous years, which proved a decided advantage, for it allowed a bigger display of early flowers. A visit to Leonard's, Horsham, by kind permission of Sir Edmund Loder, Bart., was made on August 15, and evening visits were also made to several gardens. The balance sheet shows a total income of £76 1s. 1½d. (which sum includes the value of certain stock held by the society), and a small balance in favour of the society.

CARDIFF GARDENERS.—The opening meeting of the new session of this society took place on Tuesday, January 8, at the Philharmonic Restaurant, when Mr. H. A. Evans, of the Hardy Plant Nurseries, Llanishan, read a paper on "The Herbaceous Border and How to maintain it." The lecturer gave directions for the preparing of the soil before planting, and advocated manuring and deep trenching in this operation; he recommended planting in bold groups instead of in straight lines. The lecturer also gave a comprehensive list of herbaceous plants, their season of flowering, propagation, and general cultivation. A good discussion followed, and many questions were put to, and answered by, Mr. Evans.

GUILDFORD AND DISTRICT GARDENERS.—The second annual general meeting of this association was held on Tuesday, January 8, the retiring president (Alderman F. F. Smallpeice, J.P.), presiding. The hon. secretary read the committee's report for the year, which showed that a steady advance had been made. The meetings had been well attended, the average attendance at the 21 meetings having been over 60. Exhibits at the monthly assemblies had been numerous and of exceptional merit. The summer show had been a great success in every respect. On four occasions during the year outings had been enjoyed. The number of members was 122. The hon. treasurer (Mr. W. Foreman) reported that the receipts during the year had totalled £37 6s. 8½d., and the expenditure £30 7s. 0½d., leaving a balance in hand of £16 19s. 7½d. Both the report and the balance sheet were adopted. Mr. F. Baring-Gould was unanimously elected president, and other officers were elected as follows:—Mr. H. Tann, chairman; Mr. G. Johnson, vice-chairman; Mr. Hancock, librarian; Mr. W. Foreman, hon. treasurer, and Mr. G. Bullen, hon. secretary. The committee were also elected. A very pleasant social evening in connection with the association was held at the Workman's Hall on Wednesday, January 9, when over 100 members and friends were present. G. E. B.

CRAWLEY AND DISTRICT GARDENERS.—The members of this association met on Tuesday, January 8, Mr. G. F. Banks presiding. Three new members were elected, and the association accepted the offer of Mr. H. Hobson Finch for the annual exhibition in July to be held at Goff's Hill. The subject for the evening was "Vegetables for Exhibition," the lecturer being Mr. A. B. Waddes, gardener to Sir Weetman Pearson, Bart., of Paddockhurst, Worth. A discussion followed the reading of the paper.

BECKENHAM HORTICULTURAL.—On Friday, January 4, Mr. J. A. Watson, B.Sc., of Beckenham, gave a record lecture on "Leaves," illustrated with limelight views. A number of the pictures placed on the screen were made from sections cut and mounted by members of the Society under the kind tuition of Mr. Watson. At the ordinary

meeting, held on the 11th inst., an instructive hour was spent in examining and discussing a fine case of moths and butterflies brought by Mr. Libbiter, gardener to Dr. Codd, Bromley, and who explained the life history of many of them by verbal and ocular demonstration. The whole of the moths, &c., displayed were collected and bred by Mr. Libbiter, a work extending over seven years. T. C.

CHESTER PAXTON.—The opening lecture of the present session was given on Saturday, January 12, by Mr. G. P. Miln, whose subject was "A holiday in Ireland." The lecturer's remarks were principally concerned with the districts included in the northern circular tour from Dublin, the topography of which he described in a very lucid manner. Of special interest were the photographic slides of the famous Pinetum at the seat of Viscount Powerscourt, in County Wicklow, and other views representing the beautiful surroundings of this large estate. Special reference was also made to the Botanic Gardens at Glasnevin, the extensive gardens and plantations of Phoenix Park, &c. The pictures, some 70 in number, included representations of some old Irish Celtic crosses, and Norman doorways, as well as the Giant's Causeway in County Antrim.

READING AND DISTRICT GARDENERS.—The annual general meeting of this association was held in the Abbey Hall on the 7th inst., and the president (Mr. Leonard Sutton) presided over a large attendance of the members. The annual report and balance sheet showed that the society was in a most flourishing condition. Never before has the membership (812) been so large, the financial aspect so good, or so keen an interest shown in the meetings. The attendance ranged from 80 to 175. A display of over 400 bunches of cut flowers was made on "Hospital Night." At the same meeting a collection was made in aid of the funds of the Royal Berkshire Hospital, and a sum of £8 10s. was realised. The summer outings were a success. After the reading of the report the officers and committee for 1907 were elected.

SCHEDULE RECEIVED.

ABBEY PARK FLOWER SHOW, Leicester, to be held on Tuesday and Wednesday, August 6 and 7, 1907.

THE WEATHER.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Islands, for the week ending January 12, is furnished from the Meteorological Office:—

GENERAL OBSERVATIONS.

The weather was generally dry and occasionally very bright over all the eastern and north-eastern parts of Great Britain, but in the western and north-western portions of the Kingdom the sky was more generally overcast, and precipitation was experienced on several days. The amounts were generally light, but at Glencarron on the 11th the measurement was 1.96in. Distant thunder was heard at Hillington on the afternoon of Saturday.

The temperature was above the average in all districts; the excess was less than 3.5° in England S.W. and the English Channel, but more than 4° in most other localities, and as much as 5.9° in Scotland E. The highest of the maxima were recorded on rather irregular dates. In Scotland E. and Ireland S. the thermometer rose to 55°, and all other districts to 50° or a few degrees higher. The lowest of the minima, which were mostly registered either during the earlier days or late in the week, ranged from 38° in England N.W. and Ireland S. to 34° in Scotland N., and to 35° in the English Channel.

The mean temperature of the sea was higher than during the preceding week except off the south-west and south-east of England. On all the western coasts it was generally above 46°, and at Plymouth, Salcombe, and Port Erin it stood at about 48°. On the east and north-east coasts of Great Britain it was not generally above 40°, but at Lerwick it was as high as 44°, while at Wick it touched 45°.

The rainfall was less than the normal except in Scotland N. Over a considerable portion of England the aggregate fall was less than a tenth of an inch.

The bright sunshine exceeded the normal over all the eastern, north-eastern and central counties of England and the east of Scotland, and equalled it in England S. and N.W.; elsewhere, the duration was less than the average. The percentage of the possible amount ranged from 20° in England N.E. and E., 24 in the English Channel, and 22 in Scotland E., to 8 and 7 respectively in Scotland N. and W., and to 5 in Ireland N.

THE WEATHER IN WEST HERTS.

Week ending January 16.

Day temperatures remarkably uniform.—The uniformity of the temperatures in the thermometer screen during the last 12 days has been very remarkable, the lowest being 45° and the highest 49°, or a variation of only 4°. The night temperatures during the same period were all high, and on the warmest night the exposed thermometer did not fall below 41°. Since the beginning of the month the ground has been gradually getting warmer, and is now 8° warmer at 2 feet deep, and 4° warmer at 1 foot deep than is seasonable. Rain has fallen on only one day during the past fortnight, and then only to the depth of less than a quarter of an inch, so that the percolation through the soil gauges is now very slight. The sun shone on an average during the week for 1 hour 48 minutes a day, or for 17 minutes a day longer than the January average. Nevertheless, during the present month there have been no fewer than eight days on which no sunshine at all was recorded. Yesterday was calm, but during the rest of the week the winds were, as a rule, rather high. Up to the present time this month the winds have come exclusively from some westerly point of the compass. The mean amount of moisture in the air at 3 p.m. was 4 per cent. less than a seasonable quantity for that hour. E. M., Berkhamsted, January 16, 1907.

NATIONAL POTATO SOCIETY.—We are informed by the secretary that the adjourned annual meeting of the National Potato Society will be held at the Hotel Windsor, Victoria Street, London, on Tuesday, January 22, at 8 p.m.

THE POTATO YEAR-BOOK.—On the receipt of one shilling, plus postage, Mr. W. H. ADSETT, of Hatton House, Great Queen Street, London, will supply a copy of the "official publication of the National Potato Society." We may at once say that the outlay is likely to be remunerative to various classes of potato lovers. The subject matter is varied to suit the requirements of those who want to know, those who want to grow, and those whose interests are wholly commercial. The latter class, indeed, know how to take care of themselves, so that the National Potato Society need hardly go out of its way to further their interests at the expense of the other members of the community. Its main business, we take it, should be to collect and arrange information of all kinds, to sift it, facilitate its application to useful purposes, and to diffuse it broadcast among the growers, large or small. Botany, chemistry, geography, morphology, physiology, and all the "ologies" may and should be drawn upon for the benefit of the Potato-grower. The occurrence of "mutation," a subject much discussed at the present time, is one upon which Potato-growers could throw much light, and in consideration of the results alleged to have been obtained by M. LABERGIERE and others, this can hardly be said to be a matter of academic interest only. This subject is not touched on in the present report. We have, however, the records of independent trials in various counties which cannot fail to be of value.

Obituary.

JOSEPH WILLIAM OLIVER.—Many gardeners and students of botany will learn with deep regret of the death on the 9th inst. of Mr. Joseph William Oliver, who for over 30 years was a teacher of botany and geology in the city of Birmingham. Mr. Oliver's illness, which terminated fatally at the residence of his daughter at Harborne, followed on an accident which befel him on New Year's Day, when he slipped in Birmingham and broke his thigh. The deceased gentleman, who was 74 years of age, published in 1890 through Messrs. Blackie, his well-known *Elementary Botany*, which has had an enormous sale, and has passed through a number of editions and reprints. In 1894 he published through the same firm his larger work on *Systematic Botany*, which has also been very successful. As a teacher Mr. Oliver was very devoted, and greatly endeared himself to his students by his painstaking methods.

ENQUIRIES AND REPLIES.

CELERIAC AND MANGEL WURZEL.—Can any reader inform me when these plants were first introduced. *Enquirer.*

ANSWERS TO CORRESPONDENTS.

ACACIA ARMATA: H. We could not be certain if the plant referred to in our market reports would be the same as that seen at Kew. Market-growers use many names which would not be adopted at Kew, but that referred to would be the same as given in most nursery catalogues.

ACETYLENE GAS REFUSE: W. D. See reply to A. C. W., in the issue for December 15, page 416. For practical purposes this refuse may be used as lime would be.

BOOKKEEPING: S. A. Pitman's *Bookkeeping Simplified* will be suitable for your purpose. You can obtain it from our publishing department, price 2s. 9d. free by post.

BOOKS: *Self-help.* You will find some of the information you require in *The Horticultural*

Note-Book, by J. C. Newsham, price 7s. 10d. (post free) from our publishing department; also in *The Horticultural Directory* for 1907, price 1s. 3d. (post free). We cannot undertake to recommend any particular firm of seedsmen.

CHRYSANTHEMUM: G. T. C. The white variety seen in the florists' shops so plentifully at Christmas may have been Princess Victoria. Other good white market kinds in season at Christmas are Snowdrift, Western King, Duchess of Northumberland, and Guy Hamilton.

CUT FLOWERS: T. J. The Scilly Island growers send large quantities of cut bloom to Covent Garden flower market, and they are sent at specially low rates. We think you would do better to arrange with one of the commission agents in the market than to try to get small quantities direct from the Isles. You would also be able to buy any English flowers through the commission agents in the market. Very few of the large growers care to divide their produce up into a number of consignments. You will find several good firms in our advertising columns. It might be worth your while to visit Covent Garden market and make arrangements, or you would possibly be able to do better at a market centre nearer home.

DOUBLE-SPATHED RICHARDIA: W. Wood. Many thanks for the flower. We receive a considerable number exhibiting this condition.

GRAPE MELTON CONSTABLE: E. M. M. This variety was raised by Mr. W. Shingler, gardener to Lord Hastings, Melton Constable, East Dereham, Norfolk. You will find letters from growers of this Grape in our issues for January 2, 1904, p. 12; January 16, 1904, p. 45; and October 15, 1904, p. 275.

HELLEBORUS (CHRISTMAS ROSE): S. D. D. The leaves may be suffering from an attack of a fungus disease, or from the roots being attacked with the grubs of the crane fly, as mentioned in the paragraph on page 46. Kindly send some leaves for examination.

NAMES OF FLOWERS, FRUITS AND PLANTS.—We are anxious to oblige correspondents as far as we consistently can, but they must bear in mind that it is no part of our duty to our subscribers to name either flowers or fruits. Such work entails considerable outlay, both of time and money, and cannot be allowed to disorganise the preparations for the weekly issue, or to encroach upon time required for the conduct of the paper. Correspondents should never send more than six plants or fruits at one time: they should be very careful to pack and label them properly, to give every information as to the county the fruits are grown in, and to send ripe, or nearly ripe, specimens which show the character of the variety. By neglecting these precautions correspondents add greatly to our labour, and run the risk of delay and incorrect determinations. *Correspondents not answered in one issue are requested to be so good as to consult the following numbers.*

FRUITS: J. M. 1, Adam's Pearmain; 2, Blenheim Pippin; 3, Cheshunt Pippin; 4, Withington Fillbasket; 5, Deux Ans.—L. F. W. 1, Downton Pippin; 2, Crimson Quoining; 3, Court of Wick.—Ruth. 1, Lucombe's Pine Apple Russet; 2, Beauty of Hants. (known in Kent as Bastard Blenheim).—Thos. Denny. Marie Benoist.

PLANTS: H. J. W. The two frail specimens are much withered, and the numbers detached. The large green flower with a white lip is *Angraecum eburneum virens*. The yellow flower spotted with purple at the back is *Maxillaria picta*. The spray of white flowers with yellow tips to the segments is *Masdevallia melanopus*. The other specimen is not found, only the ticket and a flowerless scrap of an inflorescence.—I. P. C. 1, *Cypripedium Leeatum*, 2, *Cypripedium insignis*.—*Constant Reader*. The labellum of the *Calanthe* is too broad for a sport from C. Veitchii. It is probably the hybrid C. Sedeni, one of the first crosses from Veitchii.—W. T. The smaller flower is *Odontoglossum Ancersonianum*; the larger one *Odontoglossum lochristense*.—V. A. R. 1, *Miltonia spectabilis*; 2, *Oncidium candidum*; 3, *Pleurothallis rubens*; 4, *Sellaginella Kraussiana*.—J. S. *Codiaeum Johannis*.—A. A. 1, *Acacia pubescens*; 2, *A. dealbata*; 3, *Haworthia margaritifera*.

NARCISSUS POETICUS ORNATUS: A. R. B. The bulbs you submit are of good flowering size and quite healthy, and should have produced flowers

under ordinary conditions of culture. Under the unnatural conditions of forcing, however, this variety requires careful and studious treatment, and you appear to have made the common error of tempting the bulbs to start too early. Such attempts have a retarding influence upon the bulbs, the latter, especially when poorly rooted, making but little headway for a long time. It would have been better to have kept the bulbs in a cold house until the end of the year, supplying ample moisture meanwhile. We are of opinion that the supply of moisture to the roots has been insufficient. Curiously enough the larger bulbs—the Dutch sample—are the more forward, the others being now in the critical stage. The Dutch bulbs, therefore, if well rooted, are in a better condition to stand an increase of heat, and so soon as the bud is clear of the bulb a considerable increase may be made. Usually the Guernsey produce would be a little earlier, but so much depends upon a long season of preparation outside, followed by a long season of cold treatment under glass. You do not say whether the two stocks were planted at the same time!

ONCIDIUM TIGRINUM: E. C. W. *O. tigrinum* and its variety *O. t. unguiculatum* require similar treatment. The cool house, or cool intermediate house, suits them well, as their treatment should be in most respects similar to that of *Odontoglossums*. But after the new growths have fully made up their pseudo-bulbs, a long and dry rest should be given until the flower-spikes appear. From your statement that the plants make good pseudo-bulbs, and yet fail to flower, we think it most probable that the continuance of water throughout the whole year accounts for the failure to flower. These cool-house *Oncidiums* also like a somewhat drier atmosphere during the time they are resting than is found usually in the *Odontoglossum*-house. It is a good plan to remove them to a cool vinery or other fruit-house to rest before flowering.

REMOVAL OF FURNITURE: Scot. Yours seems to be a hard case, but we do not think you could compel your employer to defray the cost. Join the British Gardeners' Association, and bring the case under the notice of that society.

ROMAN HYACINTHS: F. D. & Co. Two very different samples are represented by the bulbs you send, neither of which has blossomed, primarily because no flower-embryo was made in the summer of last year. It is not at all clear why the larger bulb contained no flower-bud, seeing it is quite healthy and of a size capable of yielding two good spikes at least. The other bulb is decidedly of an inferior type, such as could only be regarded as of third size and diseased withal. Judged by the appearance of the root fibres there would appear to have been a cultural error, the indications showing that the bulb has been lifted up after rooting had well commenced and been pressed down again into its original place. This would cause injury to the roots, and at about 1½ inches from the base of the bulb such injury is obvious. At that point the roots bear evidences of breakage and decay. This, however, would not account for the non-flowering of the bulbs, and although a bulb at planting time is so diseased as to be incapable of producing a single root-fibre at its base, it would, provided it contained the germ of flower spike, exert all its stored up energies to develop it.

SIDE WALLS OF GREENHOUSES: H. Many of the market growers make these walls of concrete, consisting of ashes from the furnaces and a bag of cement to two, three or four barrow-loads of ashes; or, to be more exact, one bushel of cement to five of ashes. The walls vary in thickness, but usually 3 by 2 in. quartering is used, making the walls three inches thick, and long nails are driven into the quartering, leaving them standing out far enough to hold the concrete. Sometimes cement is used instead of lime as a wash to preserve wood, and it is effectual in preventing fungus spreading, if the work is properly done.

CLAYDON PARK.

THE three villages of Claydon almost exclusively form the Buckinghamshire estate of the Verney family, the present owner of the title and its appanages being Sir Edmund Hope Verney, Bart. The estate is remote from a town of any considerable size, and forms an ideal seat of an English country gentleman. The family has been connected with the neighbourhood for some centuries, and many members, through the ages, have been eminent as warriors and sea captains, statesmen and churchmen. The estate is, therefore, interesting for its historic associations, as well as for the beauty of the mansion, the park and the gardens, and for a successful attempt to solve one of the most pressing economic questions of the day, viz., the keeping of the young English husbandman on the soil. The Claydon estate consists of some 9,000 acres, while the park, exclusive of the lake, is 400 acres in extent. The road through the park leading to the mansion is bordered by a fine avenue of old Elms, between each of which has been planted a Lime tree, so that in a few years' time, as the Elms decay and are removed, an avenue of Lime trees will take their place. The Lime flourishes exceptionally well here, and many grand specimens are to be seen.

One does not need to be on the estate long to be impressed by the fact that there is no waste land—often the case on large estates. Every yard of ground is made to produce something of value. As an instance, a large piece of waste land, formerly regarded as utterly useless, was suitably prepared and planted with King of the Pippin Apples. These trees are doing splendidly, giving an enhanced value to the estate, as well as an almost sure annual revenue in a large crop of Apples. Even in the stable-yard, space not needed for ordinary stable work is utilised for fruit trees. I must mention in passing that this said stable-yard contains a perfect specimen of the beautiful *Catalpa bignonioides*, which obtained a prize given some years ago by a contemporary gardening paper. The dimensions of this *Catalpa* are as follow:—Height, 35 feet; diameter, 3 feet from the ground, 8 feet; branch-spread, 51 feet.

The bush fruits at Claydon presented, at the time of my visit, as grand a display of fruits as I have ever witnessed. The individual bushes were sturdy and symmetrical, and trained to produce the largest possible quantity of fruit. Gooseberries were principally of the varieties Keepsake, Whinham's Industry, May Duke, and Whitesmith; while of Red Currants Fay's Prolific is the heaviest cropper. Of Black Currants, Carter's Champion and Victoria were bearing berries of very large size. The Black Currant bushes were absolutely free from the mite that is causing such devastation in many places. In these gardens are to be seen the effects of intensive cultivation intelligently carried out. The ground is made to produce two or three crops annually, and a selection is made of those subjects that either do not require the same chemical constituents or whose times of harvest do not coincide. For instance, Strawberries and Lettuces, Early Beet (to come into early use as a salad) and Carrots, Early Potatoes and Brussels Sprouts, Narcissi and Raspberry, &c., occupy the same ground. Such a cultivation is carried on with great expenditure of plant-food, which is, however, supplied principally by dry night-soil, augmented by an intelligent use of chemical manures. At the time of my visit (July), Strawberries were carrying good crops, the principal varieties being The Laxton, Laxton's Fillbasket, Trafalgar, &c. Of Apples, the varieties having the heaviest crops were Cox's Orange Pippin, Peasgood's Nonsuch, Lane's Prince Albert, King of the Pippins, and Newtown Wonder. Among Pears the varieties Williams' Bon Chrétien, Pit-maston Duchess, and Marie Louise were bearing average crops. Figs also do well in the open, frequently bearing two crops a year. In a large range of glasshouses a magnificent crop of Tomatoes was growing. About five tons of these fruits are produced every year, each plant giving some 16 to 20 pounds of fruit. The variety principally grown is a cross known as "The Cropper," raised by Mr. Milson, the gardener.

It is no secret that the surplus produce of the majority of large gardens is disposed of for profit. This method obtains on this estate, which is run on entirely business lines. The proprietor, manager, foremen, and journeymen form a co-partnership, and after 5 per cent. is paid as interest on capital, the remainder of the returns is divided *pro rata* among all the employees annually, according to their rate of wages. The books containing the particulars of each crop are admirably kept, and one could readily ascertain the amount of profits. I was assured that the men worked thoroughly well, needed very little superintendence, and were very keen on the

profitable results of their labour. The gardens are maintained in a state of high efficiency, only the varieties that produce the best in quality and the greatest in fruitfulness are grown, and no appliance that money can purchase to facilitate work and economise labour is thought too costly to obtain. Among the many up-to-date implements, I was greatly impressed by a weighing machine, which is so well adjusted as to weigh accurately from one ounce to two hundredweights. I was also shown a pruner, which could be extended to varying lengths, and which by means of a simple fulcrum gave power of half a ton. The entire management of the gardens is an admirable example of what enlightened landlordism allied with intelligent co-operation can effect.

Roses succeed well at Claydon, and at the time of my visit in July the following, among many others, were blooming profusely: Charles Lefebvre, Mildred Grant, Marie Van Houtte, Sulphurea, Hon. Edith Giffard, Souvenir d'Elise Vardon, Catherine Mermet, Ivory, Anna Ollivier, Frau Karl Druschki, Souvenir de Thérèse Levet, Princesse de Sagan, and Madame Lambard.

Proceeding through a pergola, over which roamed *Clematis vitalba* and *C. montana*, Rambler Roses, Virginia Creeper, and Golden Hop, one came to a fine piece of greensward, which in early spring is gay with Snowdrops, Daffodils, and Hyacinths. Here is planted a choice collection of *Rhododendrons*, *Azaleas*, and Scotch Roses, also trees and flowering shrubs, including handsome Yews, and good specimens of *Spiræa arifolia*, *Rhus Cotinus*, Syringas, *Sequoia sempervirens*, *Ailanthus glandulosa*, &c.

The flower beds were furnished with the usual subjects, but an interesting collection of Cactus-flowered *Pelargoniums* merited attention, while a large bed of Sutton's fine strain of *Pentstemons* made a magnificent display.

The mansion is a fine, old, red-brick structure, the oldest portions dating from Tudor times. The walls are in part clothed with suitable climbing subjects—Ivies, Roses, *Magnolia conspicua* and *M. grandiflora*, &c.; about 50 square feet on one of the towers is covered by *Ampelopsis Veitchii*, forming a pleasing feature. The view from the west front of the residence is a typical example of the reposeful beauty of English scenery. From the lawn, flanked by cannon brought home by the present baronet from India and the Crimea, stretches a wide expanse of parkland; to the left is a large plantation of some 200 specimens of *Cedrus libani* (is there another such a plantation in England?), a large spinney of Scots Pines, also a growth of *Sequoia* (*Wellingtonia gigantea*). Magnificent Oaks and Elms are planted in picturesque situations, between which may be discerned an attractive lake of 200 acres, the common Water Lily covering the greater part of its surface, while white and black swans and innumerable waterfowl disport themselves in its waters and on its banks; steeples of village churches can be seen in the distance, while far away on the horizon stretch the Oxfordshire downs.

The Oaks and Elms in the park are remarkably fine specimens. Of two Oaks measured at haphazard, one proved to be 29 feet 9 inches, and the other 24 feet in circumference at 5 feet from the ground; while two Elms were respectively 22 feet 6 inches and 20 feet in girth 5 feet from the ground.

On the extensive lawns extending on the west and south of the mansion are some fine examples

of *Cedrus libani* and *C. deodara*, Elms, Copper Beeches, and a very beautiful *Liriodendron tulipifera*; also near is an interesting pinetum containing over a hundred specimens, among which were *Cedrus libani*, *C. atlantica*, *Cupressus macrocarpa*, *C. Lawsoniana albo-spica*, *Pinus ponderosa*, *Tsuga Hookeriana*, *Cypresses* (brought by Miss Florence Nightingale—sister of the late Lady Verney—from Scutari on her return after the ending of the Crimean war), *Pinus Jeffreyi*, *Chamaecyparis filifera*, and *Thuya occidentalis*, &c.

I had the opportunity of inspecting the state rooms of the mansion; but were I to attempt to describe a tithe of the treasures to be seen, I should require an entire number of this paper. Suffice it to say, there were beautiful staircases and chimney-pieces, intricate and magnificent carving and inlaid tables. A celebrated picture of Charles I. by Van Dyck, and portraits of departed Verneys by the above-named painter and by Lely and other celebrated artists adorn the rooms; on the walls, too, hang banners of various territorial and other regiments to which members of the family have belonged. Across the lawn stands the old parish church, which contains monuments and old brasses commemorating the Verney family. One memorial is unique. A Sir Edmund Verney was standard-bearer to Charles I. at the fateful battle of Edgehill. He was unfortunately slain, and when his body was discovered, it was found that his arm had been cut off. On search being made, the arm, with the hand still grasping the handle of the standard, was discovered and identified by a ring, and that mummified hand, still grasping the standard stock, is preserved in this church, as a memento of those stirring times.

An interesting industry carried on at Claydon is the profitable utilisation of undergrowth. There are some thousand acres of woodland on the estate, and until a few years since were only used for the preservation of game. Being near the docks one day, Mr. Milson observed some hurdles being packed on board ship for export. He thought of the undergrowth at Claydon, and soon obtained orders for similar hurdles. Now a profitable industry is being carried on in exporting hurdles of Hazel, Ash and Oak. The hurdle-making is carried on in late autumn, winter, and early spring; the workmen are liberated for highly-paid harvest work in summer and autumn; consequently a high average rate of wages is earned during the whole year—sufficient to retain the men on the soil instead of competing in the over-stocked labour market of the large towns.

It was pleasing to see that much was done for the comfort, relaxation, and intellectual improvement of the journeymen and young men working in the gardens and on other parts of the estate. Most of the points for which the British Gardeners' Association is striving are conceded at Claydon. Saturday afternoons and all Bank Holidays are given; and the few who are obliged to remain at work are equitably recompensed.

The woodland, park and gardens are under the management of Mr. Isaac Milson, who has held the position for 19 years. Mr. Milson is a successful teacher, and was for some time lecturer in horticulture to the Technical Education Committee of the Bucks County Council. I heartily tender to him my thanks for his courtesy in conducting me round these gardens, and for giving me much information. *Richard T. Hesketh.*

FIG. 24.—*ANCISTROCHILUS ROTHSCILDIANUS* (NEW SP.): FLOWERS ROSE-COLOURED, WITH VARIOUS MARKINGS ON THE LIP AND COLUMN (see page 51).

NEW OR NOTEWORTHY PLANTS.

ANCISTROCHILUS ROTHSCHILDIANUS
N. SP.*

A NEW species has now to be added to the genus *Ancistrochilus*, which was wisely established by Mr. R. A. Rolfe by separating from the genus the plant known as *Pachystoma Thomsoniana*, which in many essential characters did not fit into either *Pachystoma* or any other recorded genus.

Ancistrochilus Thomsonianus was discovered by Kalbreyer in West Africa and described as *Pachystoma Thomsoniana* by the late Professor Reichenbach in the *Gardeners' Chronicle*, November 8, 1879, p. 582, and illustrated in the issue for November 15, 1879 (see fig. 25). *Ancistrochilus Rothschildianus* was obtained by the Hon. Walter Rothschild from Nigeria, and it flowered at Tring Park, Tring, and the drawing from which the illustration was prepared was made by Mr. W. G. Smith from living material (see fig. 24).

Its chief differences from *A. Thomsonianus* are as follow: its larger growth, its somewhat fleshier and softer substance, which applies to both flowers and leaves, the broader sepals, the two lower ones being in every flower of the four spikes which the plant produced so markedly connivent that in some of the flowers they

FIG. 25.—ANCISTROCHILUS (PACHYSTOMA) THOMSONIANUS.

appeared to be connate, the shorter front lobe to the lip, which has the side lobes heavily tinged with sepia-brown, and not spotted as in the other species; the broader column, and the roundish and obtuse form of the buds.

The tufted pseudo-bulbs also differ much in shape. Most of them are of the form shown on the illustration, but three are oblong, one of them being 2 inches in height and under an inch in diameter at the widest. *James O'Brien.*

* *ANCISTROCHILUS ROTHSCHILDIANUS*, N. SP.—Pseudo-bulbs on short rhizomes, varying from conical to pyriform and orbicular, sometimes compressed on the upper part, forming obtuse angles; the largest over 2 inches in diameter and covered with a thin brownish membrane, 1-2 leaved; leaves ovate oblong, 2 inches wide, 6-8 inches long, distinctly ribbed beneath. Inflorescence minutely pilose in all its parts and more distinctly on the ovaries. Peduncles erect, 6-12 inches in height, and producing 2-4 flowers on the upper half, their pedicels sheathed by ovate-acuminate bracts about half-an-inch in length. Pedicels and ovaries 1 to 1½ inches long. Flowers about 2 inches apart. Upper sepal ovate-acuminate ½ of an inch wide, and about 1½ inches long, arched forward, and slightly concave on the inner side. Lower sepals scarcely so large, closely connivent, sometimes overlapping; all the sepals rose-pink. Petals narrower than the sepals, horizontally extended, pale rose-pink; lip three-lobed, and bearing two short and four longer raised purple lines from the base, the middle ones extending into the front lobe; side lobes broad and erect, green tinged with sepia-brown; front lobe narrow and curved down in front, purple with a yellow apex. Column arched, semi-terete at the base, widened laterally on the upper half, green tinged with reddish-purple. Habitat, Nigeria. *J. O'Brien.*

CULTURAL MEMORANDA.

POINSETTIAS.

For supplying a beautiful patch of colour at this dull season of the year, I know of no stove plant to equal the scarlet Poinsettia. It certainly has the drawback of a "gawky" habit of growth when seen standing individually, yet when used in that manner or in small groups rising from a groundwork of well-flowered *Eucharis amazonica*, *Adiantum* Ferns, or smaller specimens of *Crotons* or *Kentias*, I know of no more brilliant floral picture at this time of the year. For a good many years we have grown and used a large batch in this and similar ways, and the plants have always commanded the admiration of those who have seen them. It has been suggested that a few remarks on our method of culture might be of interest to some readers of the *Gardeners' Chronicle*. I should like here to emphasise an idea I have previously expressed in these columns in reference to fruit culture, viz., that local conditions have much to do with the success or failure of some varieties. The colour of the bracts on our Poinsettias certainly does seem brighter than on other equally well-grown plants in other gardens. I am sending a few bracts for inspection. We generally grow about

singly in small pots, which are plunged in sawdust in a propagating frame.

If this is not available, an ordinary low frame, with considerable bottom heat, answers quite as well. If kept well shaded from bright sunshine, and sprayed over twice each day with rain-water, a large proportion will in due time make roots freely. Other batches of cuttings are taken off as the growths lower down the old stems become long enough. For filling the cutting pots, we use any light compost that may be at hand, adding a liberal admixture of silver sand. As soon as the cuttings are rooted, we gradually harden them off, until they are fit to transfer to their flowering pots. We use 6-inch pots generally for this purpose. More care is taken with the potting material this time. Our mixture is made up as follows: Two parts loam, one part leaf-soil and manure from an old Mushroom-bed in equal proportions, with a 10-inch pot full of deodorised night-soil or fowls' dung, and one 10-inch pot full of soot to each barrow-load of soil. We add as much clean river sand as is required, and take care that all the ingredients are thoroughly well mixed together.

When the plants have been potted, the pots are plunged in sawdust on a mild hot-bed of leaves in a sunken-heated pit, where they remain until, say, the end of September or early in October, when they are transferred to a roomy, span-roofed plant house to develop their bracts. Care should be taken with watering after repotting, as if the soil gets at all sodden, many of the young plants will go off. Not much fire-heat is required in ordinary seasons during July, August, and September, though the temperature must not be let down in dull, wet weather, or the tender roots will suffer, leaves fall off, and bracts be poor. The one-year-old plants are grown in a similar way, after being cut down to the level of the pots. As a rule, they are more hardy than those propagated in the current season. If the bracts are cut for indoor decoration, we find it necessary to sear the cut end with a hot iron to prevent bleeding. *H. J. Clayton, Grimston Gardens, Tadcaster, January 2, 1907.*

[The bracts sent by our valued correspondent were amongst the best we have seen. From tip to tip, the diameter of the bracts was 18 inches and the best bracts were 2½ inches in width. The colour was richer and more perfectly developed than is usual.—Ed.]

PLANT-NOVELTIES IN 1906.

(Concluded from page 45.)

PLANTS FIGURED IN THE "GARDENERS' CHRONICLE."—The following novelties and rare plants have been illustrated during 1906:—

- Abies Delavayi Franchet, April 7, p. 212.
- Abies Fargesii Franchet, April 7, p. 213.
- Abies squamata Masters, May 12, p. 299.
- Agave americana (flowering), Sep. 22, p. 214.
- Aponogeton Henkelianum, Oct. 20, pp. 270-1.
- Apple Allington Pippin and its parents, Jan. 6, p. 3.
- Apple Miller's Seedling, Oct. 6, p. 239.
- Apple Star of Devon, June 9, p. 359.
- Arctotis aspera, Supp., May 19.
- Arctotis aspera var. arborescens, May 19, p. 314.
- Araucaria Cookii (fruiting), Nov. 24, p. 352.
- Araucaria excelsa Goldieana, Nov. 24, p. 353.
- Aristolochia Goldieana Hooker, Sep. 8, p. 176.
- Asplenium laceratum, Oct. 13, p. 263.
- Azara Gilliesii, Feb. 3, p. 77.
- Begonia Purity, July 14, p. 35.
- Beschorneria pubescens Berger, Nov. 24, p. 350.
- Buddleia asiatica, Feb. 17, p. 106.
- Calceolaria Kewensis and parents, June 16, p. 390.
- Campanula carpatica White Star, June 23, p. 409.
- Campanula laciniata, Supp., Sep. 1.

Campanula Mayii, June 23, p. 410.
 Carduus Kernerii, July 21, p. 51.
 Carnation Britannia, March 31, p. 195.
 Carnation Elliott's Queen, March 24, p. 180.
 Carnation Nelson Fisher, March 24, p. 181.
 Carnations (Picotee) Mrs. Nigel, Gronow, and Amphion, July 28, pp. 76-7.
 Carnations Mrs. Robert Norman, Robert Craig, St. Louis, and White Perfection, Supp., Dec. 8.
 Carnation White Perfection, Nov. 3, p. 311.
 Carpentaria californica, July 7, pp. 6-7.
 Cassia remigera, Dec. 8, p. 304.
 Cassiope hypnoides, April 14, p. 226.
 Celmisia coriacea, July 7, p. 3.
 Celmisia spectabilis, July 7, p. 2.
 Ceropogon hybrida, Sandersonii, similis, and Thwaitesii, Dec. 8, pp. 383-4.
 Chrysanthemum, bi-coloured, Dec. 22, p. 436.
 Chrysanthemum Miss Till and Innovation, Dec. 15, p. 403.
 Chrysanthemum Edith Harling, Dec. 29, p. 438.
 Citrus japonica, elliptic-fruited, Jan. 27, p. 59.
 Cordyline Banksii, Oct. 6, p. 241.
 Cordyline indivisa vera, Supp., Oct. 6.
 Coreopsis Grantii, May 17, p. 162.
 Cortaderia argentea, Oct. 27, p. 295.
 Corylus colurna, Oct. 13, pp. 256-7.
 Corylopsis sinensis, Jan. 13, p. 18.
 Crocus Boryi Marathoniseus, Nov. 17, p. 335.
 Cupressus nootkatensis, weeping, Sep. 1, p. 167.
 Cystopteris montana, evergreen, April 14, p. 229.
 Dasylium glaucophyllum, flowering, Oct. 6, p. 247.
 Davidia involucreta, June 2, p. 346.
 Dendromecon rigidum, June 2, p. 341.
 Dionaea edule with female cone, Oct. 27, p. 289.
 Debregeesia velutina, Supp., April 14.
 Deutzia crenata Watereri, June 2, p. 340.
 Distylium racemosum, Nov. 30, p. 303.
 Encyphalarctos Altensteinii, Sep. 22, p. 206.
 Eranthis hyemalis, double, March 3, p. 139.
 Euphorbia Wulfenii, May 26, p. 331.
 Eustoma Russellianum, July 21, p. 55.
 Gilia coronopifolia, Oct. 20, p. 277.
 Gladiolus Mrs. Cecil Baring, Sep. 1, p. 158.
 Gloxinia, double, Sep. 22, p. 215.
 Guevina avellana, Sep. 8, pp. 174-5.
 Haplocarpha scaposa, Aug. 18, p. 124.
 Hippeastrum, singular hybrid, May 6, p. 275.
 Hippeastrum Madder Rose, June 2, p. 345.
 Hoodia Currori, July 28, p. 62.
 Hyacinthus lineatus, April 7, p. 210.
 Idesia polycarpa, Jan. 6, p. 13.

THE WEATHER AT ROTHAMSTED IN 1906.

From the meteorological records of the Rothamsted Experimental Station, Hertfordshire, we learn that the year 1906 was notable for its exceptional amount of bright sunshine, and a corresponding high day temperature, with cool nights. There were four very warm months—January, August, October, and November, but only two, namely, April and December, which were unseasonably cold.

The total rainfall for the year shows a very slight excess over the average record in this district for the previous 53 years. There were four very wet months—January, June, October, and November, while July, August, and September were characterised by drought. Throughout mid-Herts the period of drought commenced when vegetation usually becomes active and extended, with but little intermission until the end of September, with this simple exception, that on June 28th, 2½ inches of rain fell, which brought up the total rainfall of June to 3.61 inches, being nearly 1½ inch in excess of the average for this month extending over the past 53 years at Rothamsted.

From the beginning of March to the end of September there was, even with the heavy rain of June, a deficiency in the total rainfall of 5½ inches, equal to nearly 582 tons of water deficient on each acre of land, and we shall not soon forget the almost entire absence of green in the meadows and pastures and the intense heat of the atmosphere in the daytime, resembling more what we read of in tropical

countries than the usual experience of English summers.

The night temperatures were usually cool, which moderated the mean temperature very considerably, and no doubt assisted in maintaining plant-life.

The following table shows the rainfall of each month for the past year at Rothamsted, with the average amount of rainfall for each month of the previous 53 years, and the difference of 1906 above or below the average record.

Rainfall at Rothamsted, Herts, for each month of the year, 1906, the total for the year, the average rainfall of 53 years 1853-1905, and 1906 above or below the average:—

Months.	Rainfall 1906	Average Rainfall of 53 years	1906. Above or below the average (1)
	Inches	Inches	Inches
January	4.09	2.96	+ 1.13
February	2.33	1.80	+ 0.53
March	1.64	1.84	— 0.20
April	0.80	1.85	— 1.05
May	1.88	2.20	— 0.32
June	3.61	2.89	+ 0.72
July	0.42	2.66	— 2.24
August	1.25	2.68	— 1.43
September	1.15	2.49	— 1.34
October	5.30	3.09	+ 2.21
November	4.22	2.57	+ 1.65
December	2.58	2.29	+ 0.29
Yearly total	28.77	28.12	+ 0.65

(1) The sign in the last column (+) signifies above the average, and the sign (—) below the average.

The rain gauge, which is one-thousandth part of an acre in dimension, stands 2 feet above the surface of the ground, and is about 420 feet above sea-level.

The above data show a total rainfall for the 12 months of 28½ inches, against an average for the previous 53 years of 28 1-10 inches, which is slightly over 6-10ths of an inch in excess.

In regard to the underground water supply of this district, the foregoing table shows that the total rainfall for the last three months of the year, October to December, has exceeded the average for the same period in the previous 53 years by 4.15 inches, which is equivalent to an excess on each acre of land of 93,890 gallons of water. Last year, at the corresponding period, there was a deficiency of 45,248 gallons of water per acre.

The next table shows the mean temperature in the shade for each month of the year 1906, with the excess or deficiency at the Rothamsted station during the past 28 years, 1878-1905; also the number of hours of bright sunshine recorded for each month, and the number of hours above or below the average record.

Mean temperature and bright sunshine at Rothamsted, Herts, for each month of the year 1906:—

Months	Mean Temperature		Bright Sunshine.	
	1906	Above or below Average	1906	Above or below Average
	Degrees	Degrees	Hours	Hours
January	41.0	+ 4.4	75	+ 26
February	37.4	+ 0.9	85	+ 16
March	40.7	— 0.2	123	+ 10
April	44.5	— 1.1	276	+ 61
May	51.8	+ 0.6	151	— 43
June	56.6	+ 0.8	240	+ 39
July	61.6	+ 0.7	272	+ 47
August	62.9	+ 3.0	253	+ 50
September	57.3	+ 1.5	206	+ 49
October	52.2	+ 4.3	96	+ 11
November	44.9	+ 2.5	46	— 12
December	36.1	— 1.7	60	+ 18
For the year	48.9	+ 1.0	1883	+ 245

The mean temperature for the year was 48.9°, or one degree in excess of the average for this neighbourhood. Seven months gave an excessive amount of warmth, while five months gave a deficiency.

During the months of February and March there were 16 slight falls of snow, which totalled up to a depth, probably, of 5 or 6 inches. On the evening of Christmas Day a fall of snow commenced, and continued at intervals during the next two days, making an average depth of about 8 inches, which is the deepest fall of snow lying at one time in this district for about seven years.

The bright sunshine amounted to 1,883 hours for the whole year, being in excess of the yearly average by 245 hours. There were eight months above average, and four months below the average record. The sun shone, on an average, five hours each day throughout the year, which is nearly one hour a day longer than is usual in this open, country district.

So warm and genial was the month of October that several white cabbage butterflies were observed here on the 21st and 22nd days, and in the third week 33 different varieties of wild flowers were noted in bloom in this neighbourhood. J. J. Willis, Harpenden.

FORESTRY.

THE DOUGLAS FIR AS A TIMBER-TREE.

In a communication to the *Zeitschrift für Forst und Jagdwesen* for 1906, the head forester reports on a plantation of Douglas Fir which Mr. John Booth made under the auspices and with the co-operation of Prince Bismarck twenty-nine years ago. The progress has been very extraordinary. We cannot print all the details which are given in German measurements, but we may say that in the beginning of 1906 the Douglas Fir is credited with 95.68 cubic metres of timber, whilst the common Spruce (*Picea excelsa*) yielded, during the same period, only 48.64 cubic metres, so that the Douglas Fir yielded about double the amount of timber, and as the value of the Douglas Fir timber is about three times greater than that of the Spruce, it (the Douglas) has in the course of twenty-nine years benefited the planter six times more than the Spruce. Mr. Booth, who obliges us with the above details, may say with truth, "I think the question whether the Douglas Fir is a tree profitable for planting is settled."

[From specimens occasionally sent to us, it is evident that, as usual, there is considerable variation in the Douglas Fir, and that these variations are not merely of botanical interest, but that the rate of growth, and, presumably, the value of the timber are correspondingly variable. It is, therefore, of importance that foresters should study and record their observations on these variations, which are at present ill-defined.]

NOTICES OF BOOKS.

RECENT PROGRESS IN THE STUDY OF VARIATION, HEREDITY, AND EVOLUTION. By R. H. Lock. (John Murray.)

So marked has been the progress in the study of the group of phenomena included by Mr. Bateson under the term "genetics," that some general statement had become necessary for the benefit of those desirous of knowing how matters stand. It is not only that much that was previously unknown has been brought to light, but also that much that was known is shown in a new aspect. In some cases even we have to rid ourselves of old prejudices and prepossessions in order to keep pace with the recent developments of science, and especially of experimental science. It is only the few who can experiment for themselves and so obtain knowledge at first hand. A general summary is therefore needed for the benefit of those unable, from force of circumstances, to unravel the several problems for themselves. The great feature during the last few years has been the reliance on experiments. Observation, by itself, only brings to light what is. If we require to know the reason why of any phenomenon, wish

to forecast the future, or to turn our acquired knowledge to practical account, we must also invoke the aid of experiment. The trial grounds and the laboratory must take precedence over the text-book or the lecture, though they cannot altogether replace them. The present volume deals with variation and inheritance in plants and animals in their bearing upon the origin of species, and so we have in succession chapters on evolution, natural selection, biometry, mutation, hybridisation, Mendelism, and cell development (cytology), together with a concluding chapter which summarises the whole. Whilst everyone now admits that existing species are derivatives from pre-existing species, yet we do not seem to be able to arrive at any clearer definition as to what a species really is than our forefathers did. Until that question is definitely settled, there will be less of the experi-

in general adopted the Darwinian hypothesis. Are these "new" forms which De Vries has found really to be considered species? Is it certain that these "sports" are really new developments which have not existed previously, or is it not equally probable that they may have existed but have not been observed, or that they may be explained by cross-breeding? Why is that particular species mutating when others—by far the great majority—are remaining stable—at least, within what we agree to consider as specific limitations. These matters may eventually be determined by the use of the experimental method, but at present we incline to the notion that a much wider basis of experience is required before the theory of mutation can be considered as anything more than a working hypothesis. Gardeners are familiar with variations as great as those observed by

FIG. 26.—CHOISYA TERNATA FLOWERING IN DECEMBER, 1906, FOR THE THIRD TIME. HEIGHT OF PLANT, 10 FEET; LOCALITY, HAYWARD'S HEATH, SUSSEX; POSITION, SHELTERED FROM EAST AND NORTH. (See paragraph on page 10 in the issue for January 5.)

mental and more of the controversial methods of procedure. This is a misfortune that cannot be wholly avoided, but happily the direct search after the truth is progressing, and its results are so encouraging that it is obvious that to observation and experiment must be accorded far more weight than to mere argument and disputation. Whether naturalists will ever agree upon a definition of a species as distinct, on the one hand, from an individual, and on the other from a genus, is more than we can even surmise. And yet until some agreement is reached, the controversial method cannot be abandoned. When De Vries speaks of "new species" of *Oenothera* originating by "mutation" or sporting, his facts cannot be questioned, although the readiness with which naturalists have adopted his interpretation of them is a matter for surprise, especially when it is remembered how long it was before naturalists

Prof. De Vries, but it has not occurred to them to consider them as specific. Take, for instance, the Shirley Poppy: does anyone suppose that all the forms we owe originally to the perception of Mr. Wilks are separate species, or consider the infinite variety of Cabbages all derived from one species of *Brassica* growing wild in profusion on Dover cliffs and elsewhere? Are we to think of Broccolis, Cauliflowers, Kales, Savoy, the Drumheads, the Sprouts, as so many distinct species, because they now come true from seed? The range of variation in this one species is greater than what has been hitherto observed in *Oenothera*, yet no one has ventured to assign specific rank to these variants. Perhaps we ought to do so, but we venture to think the time has not yet come. The methods by which we may hope to come to some conclusion are four: (1) By observation and comparison, which is the plan adopted by the systematic

botanist; (2) statistical examination, a method coming into frequent use; (3) cultural experiments, such as gardeners have been conducting from time immemorial for their own purposes, but which now require to be carried out with more scientific aim and greater precision, and definiteness of aim; and (4) cross-breeding, which also has been, and is, carried out daily by the gardener. All these subjects are touched on in the volume before us. To those who desire to know what naturalists are doing and thinking about these matters, we heartily recommend Mr. Lock's volume. It comprises within some 300 pages a clearly-written statement, though overlaid with technical expressions, of the great problems of the origin of species, and of the manner in which those problems are being attacked by botanists, physiologists, hybridisers, students of the intricacies of cell-development, and nuclear changes, and statisticians. There can be no doubt that at no remote period practical horticulture will benefit very largely by these researches, conducted, in the first instance, with the view of eliciting the truth, and from the point of view of pure science only.

The Week's Work.

PLANTS UNDER GLASS.

By J. G. WESTON, Gardener to H. J. KING, Esq., Eastwell Park, Kent.

Pandanus Veitchii variegata.—Select the best-coloured shoots of those usually to be found growing at the base of the plant, and put them singly in small pots. Place them on a shelf in the propagating house, for they will root better in such a position than in the close atmosphere of the case or frame. Keep the roots of *Pandanus* always rather on the dry side.

Gloxinias.—The corms may now be examined and put into a warmer house in the pots which now contain them. Do not apply much water, but lightly damp them with the syringe until they have shown signs of growth, when they should be shaken out of the old soil and potted into a compost, consisting of good turfy loam, two parts, with leaf-soil and peat together, one part, adding enough sharp sand to keep the soil porous. Place the pots on a light shelf near the glass, and apply very little water during the first few weeks.

Chrysanthemums.—The earliest cuttings have probably rooted, therefore gradually admit more air to the frame, and when ready pot the plants on into 3-inch pots. Keep them well up to the light. Continue to put in cuttings of all selected varieties. Any old stools not furnishing good "cuttings" should be placed in a light and moderately warm position.

Seed Sowing.—Seeds of many choice flowering plants are very minute, and unless the greatest care is taken in handling them, some will be lost. An early start is an advantage with plants requiring a long season for growth. Begonias, whether intended for growing as pot plants or for planting in the flower-garden, should now be sown. Prepare clean pans, and fill them with a light, sandy soil. Make the compost moderately firm in the pans, and level the surface before sowing the seeds, which should be germinated in a warm house. *Gloxinias*, *Streptocarpus*, the greenhouse varieties of *Asparagus*, *Cannas*, *Cockscomb* (*Celosias*), *Coleus*, and *Medeola asparagoides* may all be sown now and germinated in a temperature of 65° to 70°, but care must be taken that the soil in the seed-pans never becomes dry, or germination will be unsatisfactory.

The winter garden and conservatory.—The rearrangement of the permanent occupants of these houses may now be undertaken, and such subjects as *Palms*, *Cordylines*, &c., that have outgrown their quarters may be transplanted to more suitable positions, or, in the case of *Camellias*, *Acacias*, *Grevilleas*, *Luculia gratissima*, and kindred plants, usually found in these houses, they may be pruned rather severely, and be kept rather drier at their roots than usual; after which treatment they will soon break into growth again, and regain their normal appearance.

Climbers should also be pruned and cleansed, thinning the growths according to the requirements of the individual plant. *Lapagerias* do

not require much thinning, and only the old, non-flowering wood need be removed, but the whole plant must be thoroughly inspected for thrip, which is one of its worst enemies. Preserve all the *Asparagus*-like growths that develop from the base of the plant. Slugs are very fond of the young and tender shoots of *Lapagerias*, and must be guarded against.

Passifloras, *Tacsonias*, *Cobea scandens*, and the variegated variety *Solanum jasminoides*, *Clematis indivisa*, and its variety *lobata*, *Swainsonia*, *Cassia corymbosa*, *Jasmines*, *Habrothamnus*, *Loniceras*, and *Rhynchospermum jasminoides* are all suitable subjects for training on wires under the roof-glass or up the pillars of conservatories. The majority of these subjects will now require judicious thinning of their growths. The main shoots should be trained thinly apart, and the lateral growth be allowed to hang in a natural manner, and thinned or shortened as required. If the plants are growing in tubs or in restricted borders, apply a good top-dressing of suitable soil that has been enriched with a small quantity of artificial manure, which is better than farmyard or stable manure for use in decorative plant houses. The present is a suitable time to plant climbers.

Asparagus plumosus thrives when planted in a shady corner of a border.

Hanging baskets of *Asparagus Sprengeri* and *Ferns* in variety make a welcome addition in the conservatory, and these can be interspersed with hanging baskets of *Ivy-leaved Pelargoniums*, *Begonias*, and other suitable flowering subjects.

FRUITS UNDER GLASS.

By ALEXANDER KIRK, Gardener to J. THOMPSON PATON, Esq., Norwood, Alloa, Clackmannanshire.

Early vinery.—The earliest vines, which are now at their flowering stage, should, if not already done, have their lateral shoots tied to the wires, and be stopped at about two or three nodes beyond the bunch. The sub-laterals should be pinched at the first joint from their origin, subsequently rubbing out all succeeding shoots. Maintain a steady degree of heat in the vinery, and do not allow it to exceed 70° at night-time and 80 to 85° by day with sun heat. When the vines are in full flower, and the weather is favourable, admit a little outside air by means of the top ventilators, but be careful to prevent cold draughts. At the period of flowering, the atmosphere of the house should be kept dry, in order to assist dispersal of the pollen, and this should be further assisted by brushing the flowers daily with a hare's tail tied to a stick and by giving the rods a good knock with the hand. It is advisable to pollinate the free setting varieties, such as *Black Hamburg*, first, for the brush will collect much pollen, some of which will find its way to the stigmas of varieties such as *Duke of Buccleuch* and *Diamond Jubilee*, that are fertilised with difficulty by their own pollen. If the roots of these early vines have access to the outside border, see that the latter is well protected from heavy rains and snow. When the fruit is set, test the inside border with the border-tester, and if it is dry, give a soaking with tepid water. *Muscat of Alexandria* should now be started into growth. Test the border, and if dry, give a good watering, but it must be remembered that this variety dislikes the least excess of water at any time.

Tomatos.—The night temperature should be 60°, and the day 5° to 10° higher. Afford ventilation daily if the weather is favourable, and maintain a dry atmosphere in the structure in which they are growing. An empty Melon pit is a suitable place for them at this season, and the pots can be placed on the old soil in which the Melons were planted. If white fly is troublesome, fumigate with *XL-All*. Young plants wintered in 2½ or 3-inch pots should now be shifted into 6-inch pots, using as a potting medium some fresh turfy loam mixed with leaf-mould, and a sprinkling of coarse, silver sand to keep the whole porous. Afford a stake to each plant, and place them near to the glass, affording a minimum atmospheric temperature of 55°, but not allowing it to exceed 70°. A vinery in which the vines are being forced into growth is a suitable place for winter *Tomatos*. Sow seeds for later supplies, and place the seed-pan on a gentle bottom heat in a pit. As soon as the seeds germinate, remove the pan near to the glass, and when the seedlings

have developed three or four leaves, pot them singly into small pots, and plunge in a gentle bottom-heat. When the seedlings have rooted in their new pots, place them again on a shelf near to the glass. Afford ventilation daily, and endeavour to have them as short-jointed and robust as possible. We prefer *Winter Beauty* to all other varieties for late winter and early spring cropping.

PUBLIC PARKS AND GARDENS.

By W. W. PETTIGREW, Superintendent of the Parks and Open Spaces in the City of Cardiff.

Control of games.—About three years ago I had occasion to seek information from a number of the leading cities and towns throughout the country regarding the method that was adopted in controlling the games played in their public recreation grounds. The result of these enquiries was a great surprise to me, as the replies received clearly indicated that the great majority of public authorities took little, if any, responsibility in the control of such games as football, hockey, and cricket when played in the public parks. From the information received, the attitude of Parks Departments generally appeared to be that, having provided the ground, and undertaken its proper upkeep, they considered that practically their duty was finished in the matter. Anyone wishing to play these or other games on any part of their recreation grounds were at full liberty to do so, as long as they did not interfere with anyone already playing there; in other words, the principle observed was simply "first come, first served."

Opposite policy.—In one or two towns I found the method they had of dealing with their grounds went to the other extreme. At these places, public recreation grounds or portions of them are rented by private clubs, who, as a matter of course, have the exclusive right to their use. Of the two methods of dealing with the ground, this is much the worse, and one would hardly expect it to be tolerated for a day in any democratic or up-to-date town. Until about two years ago, we followed the usual custom, and exercised no control over the playing of games in our recreation grounds, but recognised the right of players who were able first to occupy the ground to the use of it. Under these conditions, it was no unusual thing for a football club who were wanting a special pitch for a match, to arrange with some of their members to be out when the gates were opened in the early morning and place their goal posts in position and play more or less on the ground till it was wanted in the afternoon. In the summer time cricket pitches were "nursed" in a similar way. As a result of all this, adult players were constantly complaining to the Parks Committee that it was impossible for them to secure proper game-pitches; children complained that when the park keepers were out of sight they were driven from the positions they were occupying by older lads; parents complained that on account of teams playing so close together the recreation grounds were exceedingly dangerous for children; the general public constantly complained that as play was allowed at all times and in all weathers, the grass was worn off the ground so completely that it looked as unsightly as a bare road.

Proper management.—I suggested, year after year, that the Parks Department should remedy these matters by taking full control of all games played on its grounds. Unfortunately two words in our park by-laws prevented the suggestion from being acted upon for several years. The by-law in question states that the recreation grounds are for the "free use" of the public at all times, and it was feared by some that by taking over the control of games, the letter, if not the spirit, of the law would be broken. It was, however, gradually realised that restrictions were, after all, only put in force for the general good, and now all games in the parks are under our absolute control. No organised game is allowed unless the players have first had permission to use the ground, and even then, if it is not in a good condition, play is prohibited. It may, at first sight, seem a little strange that the result of this policy is general satisfaction to everyone concerned. As a consequence of this change, more work and responsibility have been thrown upon the staff of the department, but the satisfactory results more than repay the extra cost and trouble involved.

THE KITCHEN GARDEN.

By WILLIAM HONNESS, Gardener to C. COMBE, Esq.,
Cobham Park, Surrey.

Digging and ground-preparation generally should continue to be the chief work in progress in the kitchen garden. Unless there are plenty of cold frames at command, the sowing of seeds should still be done sparingly and with caution, particularly in cold and exposed localities, notwithstanding the mild, open character of the weather prevailing at the time of writing.

Mushrooms.—Collect sufficient droppings from the stables to make up a bed, in as short a space of time as possible, for if this proceeding takes too long, the first instalments will become spent and useless, and probably spoil the bed. During the time the droppings are accumulating, they should be kept on a dry floor in an open shed, and should be turned over daily to allow the most volatile products of decomposition to escape. In making the bed the manure should be well trodden down, or otherwise made very firm, after which the heat of the bed should increase considerably, but this should be allowed to fall again to about 80° before spawning is attempted. At the proper time the spawn, in pieces about 3 inches square and 3 inches deep, should be placed at regular distances of, say, 9 or 10 inches apart, all over the bed. Immediately this has been done, cover the bed with some good, sweet loam, which should be evenly and well beaten down.

Radishes.—"Earliest of All" and "Sutton's Forcing" are good varieties for sowing at the present time, and to save space this sowing can be made between rows of newly-planted Potatoes.

Chives.—In some kitchens these are in considerable demand for flavouring, while for salads they are often very useful. If clumps are lifted and put into boxes, placing these in an atmospheric temperature of about 50°, they will soon start into growth, which can be nicely blanched by the application of a top-dressing of fine leaf soil.

Tomatos.—A moderate sowing of these should now be made to succeed the plants raised from the sowing made in autumn; there are many good varieties on the market, but few that can excel "Lister's Prolific," with its well-known, free-setting qualities, and shapely, highly-coloured fruits. Shardlow, although not so generally grown, is worthy of a place in any garden, being free-setting, and capable of producing fruits of fine form.

Chicory and Rhubarb.—Additional batches should be lifted and placed in the Mushroom house or similar structure. The former is very useful as a salad at this season. If a constant supply of Rhubarb can be maintained, it will materially assist the Apple store which, in a good many establishments, is by this time becoming somewhat depleted.

THE HARDY FRUIT GARDEN.

By J. MAYNE, Gardener to the Hon. MARK ROLLE,
Bicton, East Devon.

The Fig.—In consequence of the exceptionally warm weather during the past summer, very little protection will be needed by these plants even in the colder counties, providing too many growths were not left at the time of disbudding. Do not allow the protective material to remain a day longer than is really necessary.

Early autumn is the best time to root-prune any kind of fruit tree, but it may still be done. The Fig quickly shows, in its long, rank growths, when its roots are beyond control. If root-pruning is decided upon, open a trench 4 feet from the stem and carefully fork the soil from beneath the tree, cutting back all strong-growing roots as the work proceeds. Pay special attention to deep, plunging roots, as it is these that specially need severing. In refilling the trench, it cannot be made too firm, and old plaster, mortar rubble or lime should be freely mixed with the soil, but no manure should be added. Any partially grown fruits should have been removed as soon as the foliage fell; they are useless, and will rob the tree of much nourishment if allowed to remain.

Spraying fruit trees.—The practise of spraying is becoming more general among fruit growers, and is the only way by which they can hope to keep insect and fungus pests in check. Fungicides and insecticides for use as sprays can be purchased in convenient quantities ready for use from the horticultural sundriesmen.

Choose a calm, dry day for the work. The Apple, Pear and Plum are the three fruits that claim most attention, yet there is no reason why other kinds should be overlooked. Caustic wash spraying will not only kill insects and fungus pests, but will also free the tree of lichen, so prevalent in the moist counties of the west.

Nuts.—Bushes may still be planted. A space of 10 feet, each way, should be allowed between the plants. Nuts are best grown in the shape of a cup on a "leg," as less suckers are produced by this method of training. Plant on high, dry ground to avoid damage to the tiny blossoms by spring frosts, which are specially severe in low-lying, damp situations. Shelter should be afforded from the north and east winds if possible, and the ground need not be the richest, providing it is well drained. Frizzled, Kentish, Red and White Filberts are all free bearing varieties, while of Cobs Pearson's Prolific, Kentish and Cosford are most reliable. The annual thinning or pruning of established bushes should be undertaken. Cut out all suckers, and now that the small pink female flowers are visible, these will be a guide to the pruner, for as many as possible must remain, and in order to ensure fertilisation, a good percentage of male catkins as well. It is advisable to have a few bushes of the Cosford Cob among the stock, for the pollen of this variety is noted for its fertility. An annual top-dressing of manure should be given bushes growing in poor, stony ground, and liquid manure applied to those growing in pasture land.

The Fruit Store.—Apples will require to be looked over very frequently, as decay will now be more rapid. Afford a little ventilation a few hours each day when the atmosphere is dry outside, but keep the structure fairly dark. On the whole, Apples are keeping well this season, but Pears lasted but a short time with us, so many varieties being ripe at the same time. Glou Morceau and Passe Crasane were valuable at Christmas. Filberts and Walnuts must be kept in air-tight utensils of some sort or they will quickly shrivel.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir Trevor Lawrence,
Bart., Burford, Surrey.

Miltonia vexillaria usually commences to grow during the month of August, and at that time the plants were repotted into rather small pots, but now that the growths are advancing rapidly, and the roots have become active and more numerous, the plants should be placed into pots of larger size. Being surface-rooting, *M. vexillaria* does not require much depth of soil, and the pots or pans used should be rather large in proportion to the size of the plants. For drainage, place a few large pieces of crock at the bottom, and fill to rather more than half of their depth with well-dried pieces of Fern rhizome, afterwards placing a thin layer of rough sphagnum-moss upon this. When about to repot a plant, carefully turn it out of the pot so as not to disturb the roots unnecessarily. Place the "ball" just as it is on the drainage material in a fresh pot, and fill in around it with a compost consisting of chopped sphagnum-moss two parts, fibrous peat one part, and leaf-soil, broken crocks, and coarse silver sand together one part. Stand the plants well up to the light in the intermediate house, and where plenty of fresh air can reach them; afford water in moderate quantities during the next few weeks, after which time the supply should be gradually increased. Examine the young growths occasionally and assist any of the new leaves which may have adhered to each other, or any flower spikes that have become fixed in the axils of the leaves. The distinct hybrid *M. Bleuana* and its varieties will require similar attention. Plants of *M. Phalænopsis* that are rooting and growing freely should be placed in a light and "airy" position in the Mexican house, applying liberal supplies of water to the roots.

Zygopetalums.—Growing in the same house as *Miltonia vexillaria* are the various species and hybrid *Zygopetalums*, and at the present time *Z. Ballii* and *Zygo-colax Wiganianus* are developing flower spikes. It will be noticed that the flower buds are encircled with a green sheath, and in this sheath yellow thrips frequently appear, often causing considerable damage to the flower buds before they are discovered. To avoid this, slit open the sheath and periodically vaporise the house with the

XL-All compound, or any other safe insecticide which may be preferred. Strong, well-rooted plants should be supplied liberally with water, and their surroundings should be kept fairly moist at all times. Plants of *Z. Mackayii* and *Z. crinitum* that are in need of more root room should be repotted, using a mixture of lumpy loam and peat, with plenty of crocks intermixed. *Z. maxillare* is found growing naturally on the stems of tree Ferns, upon which it is nearly always imported, and any plants which may have over-grown these stems should have a fresh piece of stem wired on to the top of the old one; the young, creeping rhizome of the plant will soon attach itself to the added portion. This *Zygopetalum* needs liberal supplies of water at all times.

Zygopetalum (Warczewiczella) Gibesia is now in bloom; the flowers, which are of a dark purplish violet colour, are very striking. The plant requires a damp, shady position in the Cattleya house, and to be always in a moist condition at the root; a light spraying overhead on fine, warm days is beneficial, and will prevent the attacks of red-spider.

THE FLOWER GARDEN.

By A. C. BARTLETT, Gardener to Mrs. FORD, Pencarrow,
Cornwall.

Pergolas (continued).—The present is a suitable time to thoroughly overhaul existing pergolas. If composed wholly or partly of wood this should be carefully examined, and any that is incapable of lasting for another year should be strengthened or renewed as may be necessary. Where wirework forms a part, it may be found that the recent gales have strained the fastenings and it has lost its rigidity. Should there be any evidences of insect pests, it will be wise to unfasten all the climbers and thoroughly clean the structure, using a good proportion of petroleum in the washing mixture. The bark, when left on poles, while giving a natural and informal appearance to the pergola, affords hiding places for wood-lice and many worse enemies. The loose and semi-decayed bark, at least, should be removed. Most of the climbers may now be pruned, taking care, in the case of Wistarias, not to cut the flowering shoots, and in the case of Clematis of the *C. montana*, *C. patens*, and *C. florida* types, which flower on last year's shoots, to lay as many of these in as possible. Such kinds as *C. Jackmanni*, *C. lanuginosa*, and *C. Viticella* types, which flower on the current year's shoots, may be pruned if necessary, but most of last year's growth has been killed by frosts, so that the pruning will consist chiefly of cutting out dead wood and shortening any weakly shoots. It is too early to prune Roses to any considerable extent, but those trained to pergolas do not usually require any serious shortening.

Anemones.—In many localities the planting of Anemones has to be deferred until January. But if the collection is a large one, autumn-planting should be adopted for a portion of the stock, as this method produces earlier and larger flowers. In this case the beds should now be examined, and the surface soil loosened to allow the shoots easy passage. Anemones thrive best in a deep, light, rich soil, and should be sheltered from cold winds. The distance apart and depth of planting will depend on the vigour of the varieties; as a rule 6 or 7 inches apart and 3 inches deep will be ample.

The Ranunculus requires similar conditions, and in common with the Anemones, repay for copious waterings during dry weather. When planting, allow rather less room than for Anemones, and press the "claws" of the roots firmly into the soil. Should sharp frosts set in when the shoots first appear, some protection will be necessary.

Seeds and Seed-sowing.—It is now time to sow seeds of the various sub-tropical plants, or they will not make a good display until late in the autumn. As soon as the seedlings are large enough to handle, they should be pricked off singly. Such plants as the Castor Oil (*Ricinus*), Eucalyptus, &c., where large size is a desirable object, should be afterwards transferred to flower-pots and not allowed to become root-bound. It saves time, and is much more convenient, if the packets of seeds are sorted and tied into little bundles according to their requirements in the matter of time and place of sowing.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

APPOINTMENTS.

SATURDAY, FEBRUARY 2—
Soc. Franc. d'Hort. de Londres meet,
German Gard. Soc. meet.

TUESDAY, FEBRUARY 5—
Scottish Hort. Assoc. meet.
Nat. Amateur Gard. Assoc. meet.

THURSDAY, FEBRUARY 7—
Linnean Soc. meet.
Manchester and North of England Orchid Soc. meet.

FRIDAY, FEBRUARY 8—
Roy. Gard. Orphan Fund Ann. Meeting and election of candidates, at Simpson's Restaurant, Strand, London, W.C. Friendly dinner in evening.
Roy. Scottish Arbor. Soc. Annual Meeting.

TUESDAY, FEBRUARY 12—
Ann. Meeting of Roy. Hort. Soc. at 8 p.m.; Coms. meet at 12 p.m.
Brit. Gard. Assoc. Ex. Council meet.

SATURDAY, FEBRUARY 16—German Gard. Soc. meet.

THURSDAY, FEBRUARY 21—
Linnean Soc. meet.
Manchester and North of England Orchid Soc. meet.

FRIDAY, FEBRUARY 22—Roy. Bot. Soc. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—59°8'.

ACTUAL TEMPERATURES:—

LONDON.—Wednesday, January 23 (6 P.M.): Max. 30°; Min. 25°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, January 24 (10 A.M.): Bar., 30°6'; Temp., 29°; Weather—Hard frost.

PROVINCES.—Wednesday, January 23 (6 P.M.): Max. 38° Scotland N.E.; Min. 22° Liverpool.

SALES FOR THE ENSUING WEEK.

MONDAY AND FRIDAY—
Border Plants and Perennials, Roses, Azaleas, Fruit Trees, &c., at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.

WEDNESDAY—
Hardy Plants and Bulbs, Lilliums, &c., at 12; Roses and Fruit Trees at 1.30 and 4; and following Palms, Plants, Azaleas, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris.
2,622 cases Lilliums from Japan; also large quantities Hardy Bulbs, Spiræas, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 1.
Sale of Roses, Plants, Lilies, &c., at Stevens' Rooms, 88, King Street, Covent Garden, at 12.30.

WEDNESDAY, THURSDAY, AND FRIDAY—
Three days' sale of Nursery Stock at The Nurseries, South Woodford, by order of Mr. John Fraser, by Protheroe & Morris, at 11.

FRIDAY—
Choice imported Orchids, including Cattleyas, Miltonias, Odontoglossum, also a splendid lot of Dendrobium Wardianum, Giganteum, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

So far as we know, the first mention of this destructive pest **The Black Currant Gall-mite**. Rev. M. J. Berkeley, on April 16th, 1864. The next reference we find is to a note of Prof. Westwood at the Scientific Committee on March 6th, 1869, and reported in our columns at the time. In 1901 Mr. Robert Newstead (*Journal R.H.S.*, vol. xxv., gave a valuable paper on the subject, and other observers followed, who are referred to in the number of the *Journal of the Board of Agriculture* for January. Practical growers will, however, be more interested in the proposed remedies for the pest than in any historical or entomological details. Various measures have been tried with, generally speaking, little success. Some plans, theoretically sound, are not applicable

in practice where large plantations are concerned. Mr. Walter E. Collinge, in the publication above referred to, speaks very confidently of the lime and sulphur treatment as an effective remedy. After summarising various experiments with spraying at Woburn and elsewhere, Mr. Collinge details his own trials, and comes to the conclusion that a remedy is to be secured by the simple process of dusting the bushes thoroughly with a mixture of one part of unslaked lime and two parts of flowers of sulphur. A single dusting was efficacious, but three applications, on March 31st, April 14th and May 5th, sufficed to nearly exterminate the mite. The powder was used with a small pair of bellows, but the Coronette Knapsack sprayer has since been found to be more effectual. Mr. Collinge's experiments were undertaken under the auspices of the University of Birmingham, and have been repeated with great success by other observers. The plan is comparatively so easy and so little costly that it is to be hoped our growers will immediately take steps to repeat the trials for themselves and rid our plantations of an abominable pest. The work requires to be done thoroughly and at the right time, when the insects are migrating, say from the middle of April to the middle of June.

OUR SUPPLEMENTARY ILLUSTRATION.—

When grown in a mass on grassy banks few plants exceed in beauty of effect the common meadow Saffron (*C. autumnale*). Its value is enhanced by the fact of its flowering outside at a dull period of the year. Although the individual flowers of this species (which is a native of this country) are not so large as those of *C. speciosus* from the Caucasus, they are produced freely in a long succession, and make up in quantity what they lack in size. The group shown in the supplementary illustration has been growing at Kew undisturbed for the last 15 years, and the plants have formed large clusters of corms, writes Mr. IRVING, each of which produces on the average about six flowers of a rosy-purple colour. The bank is a sunny one, where the corms get well ripened in summer, but at the same time there is plenty of moisture within reach of the roots during the growing period. Colchicums do not succeed well on light, sandy soil, and many failures have resulted from planting them in such. There are several varieties of *C. autumnale*, including single white, double white, double purple, and forms with striped flowers. There are several other species closely allied to this, like *C. byzantinum*, *C. cilicicum* and *C. Tenorii*, all closely resembling it in flower. One of the most distinct is *C. variegatum*, with its peculiar chequered flowers of violet and purple, but it is not usually so free flowering as *C. autumnale*. *C. Parkinsoni* is a large eastern form of this species. The largest flowered kinds are *C. speciosum* (of which there is a beautiful white variety); *C. giganteum*; and the handsome *C. Sibthorpii*.

ROYAL HORTICULTURAL SOCIETY.—Mr. ARTHUR J. GASKELL has been appointed to succeed Mr. SEDGWICK as assistant secretary.

SURVEYORS' INSTITUTION.—The next ordinary general meeting will be held on Monday, January 28, 1907, when a paper, entitled "The Uses of a Geological Collection" (illustrated by lantern), will be given by Dr. HENRY WOODWARD, LL.D., F.R.S., F.G.S., V.P.Z.S., late Keeper of Geology, British Museum, more particularly referring to the Institution geological collection which he has recently classified.

THE LABORATORY AT WISLEY.—Mr. J. F. CHITTENDEN, of the Chelmsford Laboratory, and secretary to the Scientific Committee of the R.H.S., has been appointed director of the laboratory. He will take up his duties in June next. The society may be congratulated on this very important appointment. In securing the services of Mr. CHITTENDEN they have attained not only a competent teacher, but a man well qualified to undertake original research in those subjects of scientific interest directly bearing on practical Horticulture. It must be long ere we can hope to rival Versailles and other Continental, and especially American, institutions, but it is something to have made a good beginning.

THE JOURNAL OF THE KEW GUILD.—There is a freshness and a feeling of good fellowship about this periodical which are very refreshing and render it always welcome even to those who have not the good fortune to be able to style themselves Old Kew men. The present number opens with a portrait and a short notice of the new Director, Lieut.-Colonel PRAIN, who comes to Kew with an enviable record of multifarious, good, sound work, accomplished amid almost overwhelming routine duties and many journeys in Bengal, Assam, Sikkim, Tibet, Burma, Madras, the Andaman and Nicobar islands. Whilst the gardeners in the London Parks are stated to receive pay at the rate of 27s. a week, those at Kew receive only 21s. This is an anomaly that requires reformation. The letters from "Old Kewites" in various parts of the world are particularly interesting, and the more so from their unconventional tone. The report of a lecture on India, by Colonel PRAIN, before the Kew Mutual Improvement Society, is valuable for the large amount of useful information that is compressed into five or six pages.

THE JOURNAL OF AGRICULTURAL SCIENCE for January, 1907, has an important article on the improvement of English Wheat by Messrs. A. HUMPHRIES and R. H. BIFFEN. Plant improvement has in the past been "too much associated with efforts to obtain greater yield, shapeliness, colour, &c., whilst results of great value are to be won by seeking for that most subtle of attributes—quality." This is no doubt true; moreover, it is, we think, attributable to two main causes—the desire to obtain commercial benefits as soon as possible, the other to the not always healthy emulation produced by the exhibition table. Both these factors are of great value, but they should be subordinated to experiments with the object of attaining increased knowledge without reference, in the first instance, to more practical results which are sure to follow. The most important practical results are those which arise, in the first instance, from researches of a purely scientific kind, which the practical man should know how to utilise.

"MY GARDEN DIARY."—Messrs. SUTTON & SONS, Reading, have prepared, as in former years, a useful little book bearing this title. In addition to pages for monthly memoranda it has many seasonable "reminders," and also lists of the best plants for cultivating in special conditions and positions. The cover shows a coloured picture of flowers of a Polyanthus or Bunch Primrose which, we understand, was grown last year by Miss JEVILL in Munstead Wood Gardens. The blossoms shown are golden and white with a large gold centre, both handsome and effective.

"ONE & ALL" GARDENING.—This periodical, which issues annually from 92, Long Acre, W.C., is full of useful notes as well as of articles that garden lovers will appreciate. The editor, Mr. E. O. GREENING, under the title of Country in Town, mentions what is done and what may be done even in the most unpromising localities in and near cities. This, the twelfth issue of the Annual, is, as usual, abundantly illustrated.

Photo by E. J. Wallis.

COLCHICUMS IN SEPTEMBER IN KEW GARDENS.

Temple Press Ltd., Printers, 7-15, Rosebery Avenue, London, E.C.

THE RAINFALL IN 1906.—In a recent issue (see also p. 52), Mr. MAWLEY, who is as ardent a meteorologist as he is a Rosarian, stated that the year's rainfall was about an average one, but that by far the greatest quantity of rain fell during the months of January, February, and October. Several correspondents have kindly furnished us with tables of the rainfall in their districts, and their records show how remarkably heavy the rainfall was during these three months, especially in January and October. Thus Mr. BAYFORD, Shugborough Gardens, Stafford, recorded 4.48 inches and 4.96 inches during these months respectively, while in July his record was only 0.77 inch. In October more than 1 inch of rain fell in 24 hours. His total amount for the year was 31.15 inches. Mr. WM. J. SHORT, Freeland Lodge Gardens, Woodstock, had a smaller total fall in 25.36 inches, the wettest month in his district being October with 4.66 inches, January following with 4.15 inches. In each of the two months, April and September, less than an inch of rain was recorded at Freeland Lodge, the figures being 0.56 and 0.97 inch respectively. On three occasions more than an inch of rain fell in 24 hours in these gardens, the greatest fall being on June 29, when 1.53 inch was recorded. Mr. H. BERRY, Wilton Park Gardens, Beaconsfield, Bucks., recorded the large amount of 5.52 inches during January and three other months—June, October, and November—each with more than 3 inches, but as April, July, and August were very dry months, the average, 28.06, was about normal. Mr. H. WILSON, Coleorton Hall Gardens, Leicester, had a similar average to the last-mentioned in 28.01 inches, but here the wettest month was October, with 5.60 inches. April and July were the driest months, which reads peculiar for April, the month usually associated with umbrellas and spring showers. On 178 days a measurable quantity of rain fell in these gardens. Wells, which had never before been known to give out, failed last season, but the last three months supplied the deficiency of the earlier part of the summer months. Mr. J. B. LOWE, D'Abernon Chase Gardens, Leatherhead, recorded a total all for the year of 24.9 inches as against 23.16 inches in 1905. Rain fell on 157 days. The heaviest fall or 24 hours occurred on June 28, when 1.59 inch fell. The wettest month of the year was January with a total rainfall measuring 4.83. Mr. H. PARR, Trent Park Gardens, New Barnet, recorded a total rainfall for the year ending 1906 of 26.09 inches. Mr. V. A. COOK, Leonardslee Gardens, Horsham, Sussex, recorded a total rainfall of 29.84 inches for the past year. Leonardslee experienced 168 rainy days, the wettest being January 3, when more than 1 inch of rain was registered. January was the wettest month with a total rainfall of 5.1 inches, but November was not far short of this total with 5.39 inches. August was a very dry month in this district with only nine days on which a measurable quantity of rain fell, the total for the month being .61 inch. Throughout the year there were more than 5 inches of rain in excess of the total fall of 1905. In Osberton Gardens, Worksop, Mr. JAMES ALLAN informs us the hottest day of 1906 was September 2, when the thermometer registered 93° in the shade, and the coldest December 26, when there were 21° of frost. The heaviest rainfall occurred on October 18, when 1.9 inch of rain was recorded. The total rainfall for the year in these gardens was 22.34 inches.

THE WEATHER AND THE CROPS.—According to Mr. SHAW in the *Journal of Agricultural Science* (January, 1907), autumn rainfall is deficient for preceding good Wheat years and excessive for the bad, and the character of the season for the good years is the opposite of the corresponding season for the bad years. "A good Wheat yield is preceded by a dry and warm autumn, a rather dry and warm winter, a rather wet and cold spring,

and a dry and slightly warm summer; whilst a bad Wheat year has a wet autumn of average temperature, a wet and cold winter, a dry and warm spring, and a moist, warm summer." The time at which the Wheat is sown has also to be taken into consideration.

WATER SUPPLY FOR ESTATES.—We have received a very handy little leather-covered pocket book from Messrs. HAYWARD-TYLER & CO., LTD., 99, Queen Victoria Street, London. In addition to having the usual calendar and diary for 1907, it contains much useful information relating to the supply and control of water in mansions, on estates, in villages, &c. Messrs. HAYWARD-TYLER & CO., LTD., state their willingness to forward a copy to gardeners or estate agents on receipt of professional card or noteheading.

WINTER-SPRAYING OF FRUIT TREES.—In the January number of the *Journal of the Board of Agriculture* mention is made of various experiments with insecticides carried out by Mr. W. E. COLLINGS, of the University of Birmingham:—"Out-of-door experiments were commenced in March, 1906, with the following spray-fluid:—Caustic soda (98 per cent.), 2 lb.; soft soap, $\frac{1}{2}$ lb.; paraffin, 5 pints; soft water, 10 gallons. The soft soap was dissolved in a gallon of boiling water, and whilst still hot the paraffin was added and beaten up into a creamy liquid. The whole of the liquid was then pumped with force through a fine spray nozzle in the usual manner into another vessel. The caustic soda was dissolved in 9 gallons of rain water, and into this solution the paraffin emulsion was then poured, and the two well mixed together. This spray-fluid gave excellent results, and it is proposed to substitute it in future for the caustic alkali wash of caustic soda and carbonate of potash. In all probability this spray-fluid will prove effective in destroying the eggs of all aphides, and the red spider also, though it has not yet been tried upon the latter pest."

"PROGRESSUS REI BOTANICÆ."—This is the first part of a publication devoted to the progress of botany, and edited by Dr. LOTSY, of Leiden. The first article is by Dr. STRASBURGER, and is a record in German of the progress made in our knowledge of the cell and its contents since 1875. This occupies no fewer than 138 pages, and will, we trust, be translated into English. Dr. SCOTT follows with a paper on the present position of Palæozoic Botany. There is no evidence of the existence of flowering plants in those early days. These do not appear until the mesozoic epoch. Gymnosperms (Conifers) and allied plants, together with Ferns, were very abundant. Many of the plants formerly classed with the Ferns are now found in the Pteridospermæ, a class intermediate between the Ferns and the Gymnosperms, having the seeds of the latter, but the more simple organisation of the former (Filicales). A third paper is by Prof. FLAHAULT, of Montpellier, and is a masterly summary of the progress of botanical geography since 1884, in which the necessity for determining species and their relationship to the conditions under which they live is insisted on. This paper is one which may be read with profit by those concerned in the cultivation of plants, and desirous of knowing how plants live and adapt themselves to the circumstances by which they are surrounded.

THE VINTAGE IN FRANCE IN 1906.—According to some statistics before us the total production is computed at 51,042,866 hectolitres, over a total area of 1,771,964 hectares (one hectolitre = 22 gallons, one hectare = 2½ acres nearly). The figures show a considerable deficiency as compared with the results in 1905. The colour and quality are reported good.

CHANGE OF SEX IN FLOWERS.—In the Bulletin of the Botanical Society of France (1907), M. CAMUS relates his observations on the change of sex in Willows. In some cases he was, he says, able to satisfy himself that the same male shrubs bore one year branches provided with male catkins, and the following year female catkins or ♀ catkins mixed with ♂, and without being able to determine any order in these changes. Having carefully noticed one large branch which had only yielded ♂ catkins he was surprised the following year to see it furnished entirely with ♀ catkins. Further observation showed that the branches bearing male flowers were always those which seemed to suffer or to have suffered from too long an immersion in water, branches not immersed or removed from water rarely bore any but ♀ flowers. In reference to this subject it is noted by M. GERBER that one plant of *Pistacia terebinthus*, at the foot of which water was flowing, bore in one inflorescence male flowers, female flowers, and hermaphrodite flowers while other plants of the same species, that were in dry soil in the vicinity, bore unisexual inflorescences. The following year the water had ceased flowing in the canal that ran at the base of the abnormal *Terebinth* and the inflorescences of the plant had again become unisexual.

"THE QUARTERLY JOURNAL OF FORESTRY."—We are pleased to welcome the first number of a new journal devoted to forestry. The annual reports of the English and Scottish Arboricultural Societies are valuable and interesting, but more frequent intercommunication is necessary. The first part of the new journal has been prepared by Mr. A. C. FORBES, but his removal to Ireland has necessitated other arrangements, and Prof. FISHER, of Oxford, late of Cooper's Hill, will in future act as editor, with the assistance of a Publication Committee. The proceedings of the Royal English Arboricultural Society will henceforth be included in the journal. In the present number there are interesting accounts of Kilmington, Bickton, Endsleigh and Poltimore, as visited by the society. Mr. ELWES succeeds Prof. FISHER as president. On p. 80 we note that *Picea Engelmanni* is entirely unaffected by frost in Norfolk which injured *Abies Pinsapo* and *A. cephalonica*. In our limited experience we have found *P. Engelmanni* materially injured, or even killed, by frost on the London clay, whilst its close ally and near neighbour *P. pungens* was unhurt.

THE FERNS OF WESTERN CHINA.—In the *Bulletin of the Académie Internationale de Géographie Botanique*, Nos. 199-201 (1906), Dr. CHRIST, of Basle, catalogues the Ferns collected by Mr. E. H. WILSON on his journeying in Western China and Eastern Tibet for Messrs. JAMES VEITCH & SONS. Some 160 species and varieties are enumerated, of which, so far as is at present known, 74 are exclusively Chinese, whilst 60 others are found also along the Himalayas from Assam to the frontiers of Afghanistan, where they disappear. The great mountains of Szechuan, Yunnan, and Eastern Tibet form a centre from which have gradually spread to the Himalayas, by means of moist currents passing from east to west over the dry plains of Bengal, to be condensed on the slopes of the Himalaya. As many as 21 new species, and 11 new varieties are enumerated. It is interesting to compare the results obtained by Dr. CHRIST among Ferns with those relating to the Conifers of the same district recently published in the *Journal of the Linnean Society* (1906), by Dr. MASTERS.

GUERNSEY BULBS are preferred by some growers to those from Holland for early forcing purposes. They come in earlier probably because they ripen earlier, but they are not so large as the Dutch bulbs.

SEASONAL BOTANY.—This is described as being a supplementary text-book, including, I. Outline course of general botany, and II. Detailed course of physiological botany, by M. O'BRIEN HARRIS, D.Sc. (Publishers, Messrs. BLACKIE & SON, 50, Old Bailey, E.C.). The writer wishes her work to be supplementary in two points: in assisting teachers to adapt the text-book course to the round of the seasons, and in the preparation of physiological experiments. For the latter, she suggests some convenient objects of study, while the practical work is to extend over two years and be pursued with reference to the seasons of the years. Teachers in want of a plan on which to base their instructions, or whose other books do not inspire them in this direction, may find the hints

(tab. 2,816). Many of WILSON's novelties from western China are published and Mr. HEMSLEY supplies a monograph of the genus *Corylopsis*. We are glad to notice the resumption of the capital letters in the specific names of plants named after persons, even when the names are used in the form of an adjective, as in the above cited *Stevia Rebaudiana*.

STEREOSCOPIC FLOWER RECORDS IN NATURAL COLOURS.—Examples of Mr. WALTHAM's coloured stereoscopic representations of Orchids and other flowers may now be seen in the Botanical Room of the Natural History Museum, at Cromwell Road. The time seems to have come for the camera to replace in some measure the water-colour drawing for scientific purposes,

Publications Received.—*Report of the Agricultural Organisation Society*, for the 18 months ended June 30, 1906. This society is now nearly six years old and was formed for the purposes of co-operative work and enterprise. It is well supported and in a satisfactory condition.—*Agricultural Bulletin of the Straits Settlements*, October, 1906, edited by H. N. Ridley and J. B. Carruthers. This is chiefly occupied by notes on different species yielding rubber.—*Annual Report on the Gardens of His Highness the Maharana Fateh Singhji Badakur, of Udaipur, Mewar*. This is interesting as mentioning the different conditions under which tropical cultivators have to work. An unprecedented frost did some damage in January, 1905, and uninvited visitors from the neighbouring jungle were a source of possible danger unknown in European gardens. Notwithstanding drawbacks, the year was one of successful effort.—From the Board of Agriculture and Fisheries—*Leaflets 173, Potato Growing in Yorkshire*; No. 178, *Onion Mildew*, and No. 185, *Bean Pod Borer*.—Louisiana Experiment Station, Bulletin No. 87.

FIG. 27.—VIEW OF THE LAKE IN THE GREENWICH PUBLIC PARK." (See page 59.)

of the present writer acceptable and practical. It would be well if all young gardeners had to pass through a practical training of this sort before undertaking garden work proper. The little book before us shows how such education could be given at a minimum of cost and trouble in any village school presided over by a competent teacher.

HOOKE'S ICONES PLANTARUM.—This publication devoted to the description and illustration of new or interesting plants contained in the Herbarium at Kew is now edited by Col. PRIN, the director of the Royal Gardens. Among many others we note descriptions of two new species of *Nepenthes* by Mr. HEMSLEY, and an account of the remarkable Sugar plant from the highlands of Paraguay, a Composite called *Stevia Rebaudiana*

especially where details and diagrammatic analyses of the construction of the flower are not needed. Although stereoscopic or relief photography dates back almost to the time of Daguerre, it has not been of much real value to the scientist on account of the difficulty experienced in getting results true to nature; but in the hands of Mr. T. E. WALTHAM this difficulty no longer presents itself, for by his colour-process he is able to reproduce clearly and faithfully the venation and texture of a flower or leaf. To anyone possessing ordinary vision the brain is thus able to appreciate the effect of true colour and relief through a stereoscope, the picture being obtained by focussing the two lenses on to the object from two points of view, exactly as is done in the human eyes.

Analyses of Commercial Fertilizers and Paris Green.—U.S. Department of Agriculture, Bureau of Entomology, Bulletin No. 62. *The San Jose or Chinese Scale*, by C. L. Marlatt, and *Revision of the Tyroglyphidae of the United States*, by Nathan Banks.—*Willing's Press Guide*. The present volume is the 34th annual issue of this book, which has become as a matter of course a requisite on the shelf of every editor. It contains full lists of all British and of some foreign newspapers and periodicals so classified as to be quite easy for reference. The book appears to grow a little stouter each year as if the number of periodicals were still steadily increasing.—*Annual Reports of the Jamaica Board of Agriculture, Public Gardens and Plantations*, to March 31, 1906. Mr. W. Fawcett reports favourably upon the agricultural experiment work and upon the work in the Gardens. Advance was noticeable in all departments.—*Bulletin of the Jamaica Department of Agriculture*, December, 1906. Contents: Ramie Grass, fibre machine, cultivation of vegetables.—United States Department of Agriculture, *Farmers' Bulletin*, No. 54. *Some Common Birds in their relation to Agriculture*, by F. Beal.

FLORISTS' FLOWERS.

CHRYSANTHEMUMS FOR EXHIBITION.

HAVING made an audit of the prize stands of Chrysanthemums, I enclose a list of the first 36 Japanese and 24 Incurveds with the number of times each variety was shown. I have audited the first prize stands of all the principal shows throughout the country. I find to get at the most consistent varieties this is a very good method, and to do it annually. One sees the rise of new varieties and the falling away of older sorts. For instance, this year, it will be observed, amongst the Japanese, the new varieties Reginald Vallis, Mrs. A. T. Miller, and Algonon Davis have been shown most consistently, and doubtless should be grown by every exhibitor; whilst such as W. R. Church, Mrs. Barkly, and Mrs. W. Mease, which a few years ago headed the list, are now very low down the scale. This should be a guide to all amateurs and young exhibitors.

86 BEST JAPANESE VARIETIES.

1 Mr. F. S. Vallis ... 64	19 General Hutton ... 12
2 Mrs. W. Knox ... 40	20 Mrs. J. Dunn ... 12
3 Bessie Godfrey ... 32	21 Mme. J. Rivol ... 11
4 J. N. Silsbury ... 29	22 Mrs. A. H. Lee ... 9

—H. S. Kemp, 21, Shortlands Gardens, Shortlands, Kent.

ODONTOGLOSSUM BEAUTE CELESTE x.

At fig. 28 we reproduce one of Mr. Charles Vuylsteke's latest hybrid *Odontoglossums*. It was raised from *O. ardentissimum* x *O. crispum*. The flower is of remarkably fine build, massive in all its segments, but of first-rate form, the side petals being pure white and very wide, the segments of the outer whorl and the lip being spotted. The lower portion and fringe of the lip are white.

NOTES FROM GREENWICH PARK.

APART from its pleasant situation and historic associations, Greenwich Park contains a great deal that is of interest to the lover of gardening, and especially of trees and shrubs. The avenues of fine old sweet Chestnut and Elm, which were planted at the instigation of Evelyn in the 17th century, and the rich collection of trees and shrubs—by far the finest in the London parks—are all worthy of inspection. The accompanying illustration (fig. 27) of the lake in Greenwich Park shows what can be done in converting a disused gravel pit into a place of interest and beauty, for not so many years ago the site of the ornamental water was an eyesore and blot on the landscape, being but a series of holes from which materials were taken for the making and upkeep of the park-roads and paths. Now, however, all is changed, and by the aid of some hundreds of loads of good soil the sloping, gravelly banks have been converted into suit-

able beds for plants, and by careful puddling of the bottom an abundance of water is at all times maintained. Amongst aquatic plants the better forms of Water Lily, the Cape Pondweed, Bogbean, Water Soldier, the Water Plantain, and hosts of other beautiful subjects have been introduced; while in dampish ground by the water margin the Mocassin flower (*Cypripedium spectabile*), the Madeira Orchid (*O. foliosa*), Gunneras, Royal Fern, *Eryngium pandanifolium*, and great reed all find a congenial home. Amongst the old Oaks and other trees on the grassy sward by the lake side, big irregular breadths of Daffodils, Snowdrops, Chionodoxa, Wood Hyacinth, Croci, and Winter Aconites have been planted, and in spring contribute largely to the adornment of one of the sweetest spots, as the late Mr. Burbidge called it, that is to be found anywhere in the great metropolis. A. D. W.

Chartreux, in 1786, falls into the same error, and it was not until the botanist Poiteau made a careful investigation of the subject that the real facts of this botanical curiosity became evident; we cannot do better than translate his remarks. "One reads stories more or less amusing about this Apple written by persons who, being ignorant of the structure of a flower, think that it is non-existent because it has no petals, and lift amazed hands at a tree which produces Apples without flowers. They are mistaken. The tree flowers, but the petals are small and green, in addition to which this flower has a remarkable peculiarity which is not seen in any other. The flower is unisexual, the anthers are entirely wanting and the styles are tripled; they number 15 instead of 5." Here we see for the first time the true explanation of the want of seeds which distinguished this fruit, and it is curious to speculate how much the Romans appreciated this fact when they named it *spadonium* (castrated); as it is generally supposed that a knowledge of the functions of pistils and stamens is a comparatively recent acquisition. Leroy in his

FIG. 28.—ODONTOGLOSSUM BEAUTE CELESTE x.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

THE SEEDLESS APPLE.—The subject of the seedless Apple has lately been much in the public mind, as it was but a few months ago that this reputed new star in the pomological firmament was first billed, with all the resources of the modern advance-agent, as about to make its appearance in the Western Hemisphere. A certain indecision seemed to reign in the mind of its alert and enterprising sponsor as to whether it should be "seedless" or "coreless." However, the arrival of the fruit itself soon settled this momentous question; it was found to be neither. To those that believe that to search for novelty beneath the sun is vain, it may, perhaps, be interesting to read the history of this curious fruit from the earliest days, as there is little doubt that it is one identical variety which has figured under various names in the course of its long and varied experiences. The first mention of a seedless Apple occurs in the *Historia Naturalis* of Pliny, which naturally carries us back to the first century of our era. The Apple was then growing in Belgium under the name of *Spadonium*, the significance of which name we shall see later, and the fact that it bears no seeds is specially mentioned. From this early date a long leap has to be taken to the year 1690, when the pomologist Quintinye mentions it, and from a superficial examination concluded that it did not flower, and therefore named it *Sans fleurir*.

Dictionnaire described the fruit under the name of *Figue d'Hiver*, and the fruits he grew were completely devoid of seeds. From his description of the aborted embryos one would gather that if cross fertilised it would produce seeds. Of the many legends circulated in olden times about this fruit we may mention one quoted by Etienne Calcel in 1805. The first grafts were supposed to have been taken by Adam from the Terrestrial Paradise and the name of *Pomme d'Adam* was commonly attached to this variety. The writer somewhat naively adds that "this story is somewhat doubtful," and certainly from a physiological point of view the name of *Pomme d'Eve* would have been more suitable. Coming to later times there seems little doubt that this is the Apple referred to by Darwin as the *St. Valéry*, and which at its flowering time was fertilised by maidens of the district with pollen from their favourite Apple trees, and which in due time produced fruit exactly corresponding to that of the pollen-parent. We have been unable to trace any variety in France under this name. From the above-quoted instances of the comet-like appearances of this singular fruit its next appearance under a new name is a matter of uncertainty, but this short account may perhaps prevent it being acclaimed as a new creation by that section of the Press whose enterprise is only equalled by their credulity [and that of some of their readers]. *Nemo*. [Many details relating to the structure of this Apple are cited in Masters' *Vegetable Teratology*, p. 292, fig. 152, &c., &c. Pliny, as our correspondent points out, mentions (Book xv., cap. 14)

"spadonium,"—"a conditione castrati seminis-que Spadonium appellant Belgæ," on account of the total absence of pips. Chabreaus' *Stirpium Icones* (1666), p. 1, figures the flower and fruit, and refers to Gesner, Camerarius, and even to Theophrastus. "Malum dari quæ non floreat et tamen fructificet, tradit Gesnerus in Appendice . . . Solet vero hoc Mali genus carere seminibus et est forte illud cuius meminit Theophrastus 3, de Caussis, quod Malum vernam vocat et fructum edere ait sine nucleo." Parkinson's *Paradisus* (1629), p. 588, says: "The Apple without blossome, so-called because although it have a small shew of a blossome, yet they are but small threads rather than leaues, neuer shewing to bee like a flower, and therefore termed without blossome; the Apple is neither good eating nor baking fruit." In the *Theatrum*, p. 1,502, the same author mentions another [Apple], which hath no kernels within the core, and Miller, in his *Gardeners' Dictionary*, also mentions it, but apparently had not seen it. It is said to be the *passé-pomme* or *grillette* of the French.—Ed.]

RHODODENDRON BARBATUM.—This Rhododendron, the first species to flower in the new year, is not so difficult to cultivate as many persons imagine. The flowers, which are bell-shaped and blood-red in colour, are produced in trusses. The "bells" measure from 1½ to 2 inches across, and, when seen on a dull day at the end of January, or throughout February, are particularly pleasing. The leaves are long and pointed, and at their base is a cluster of strong, hairy spines that form a protection against the raids of small insects: hence the specific name. A greater pest in this country than insects are birds, especially tom-tits, which commence to pull the flowers to pieces as soon as they open. In these gardens the flowers are protected by covering some close-mesh netting high up over the tree, so that the flowers can be seen. The flower-buds are now swelling, and showing slight signs of colour. Last year the inflorescences were at their best stage about the middle of the present month, and they continued in good condition till the end of February, but the late severe weather has somewhat retarded them this season. These Rhododendrons should be afforded a little shade from the mid-day sun in summer. They flourish in a mixture of loam, leaf-soil, and manure, with a small addition of peat. They need plenty of water at their roots throughout the summer, and mulching is of very great service at all seasons. *W. A. Cook, Leonardlee Gardens.*

CATERPILLARS ON APRICOT TREES.—For several years up to the last one our Apricot trees, on a south wall, were injured by caterpillars eating the young leaves. We hand-picked thousands from the trees and applied several forms of insecticide, which, although checking them somewhat, did not get rid of them. Twelve months ago I decided to remove carefully the whole of the soil a foot in width and depth at the base of the wall, wheeling it on to a flat about to be trenched in the kitchen garden. When doing this we were careful to put the wheeled soil at the bottom of the trenches. Before putting fresh soil at the base of the wall we gave it a good dressing of fresh soot, mixing more soot and wood ashes with the soil. We then removed all the smaller branches of the trees from the wall and gave the walls a thorough syringing with soap-suds from the laundry, adding a wine-glass of paraffin to each gallon. Last year we did not see a sign of caterpillars. *H. J. C., January 14, 1907.*

MANGEL WURZEL.—In answer to *Enquirer* (see p. 48), it may be stated that the Beets of cultivation are natives of the south of Europe. Two kinds are mentioned by Pliny, the black and the white, and he states that the root was held in great esteem by the Greeks, and formed one of their votive offerings to Apollo in his temple at Delphos. The red Beet was introduced to this country in 1548, and the white variety in 1570. The varieties of the Beta vulgaris are classed as B. vulgaris campestris, field Beet or Mangel Wurzel, which means "scarcity root," and B. vulgaris hortensis, garden Beet. In the former are included all those of greatest importance to the agriculturist, and in the latter such as are chiefly confined to garden culture, and some of which are well known as valuable esculent vegetables. *J. J. W.*

THE PREVENTION OF CORRUPTION BILL.—The practice which has generally prevailed of seedsmen and other traders giving to gardeners a percentage—usually 5 per cent.—on the amount of their employers' purchases is now illegal. It is clear it is a most reprehensible custom, tempting honest men to order and consume more things than are necessary; but what I want to know is what will be done with the 5 per cent. saved? Will the nurseryman give it as discount to his customer, either directly or by reduction in price, or will he retain it as extra profit? It will be a wholesome change if employers have to raise the wages of their gardeners instead of allowing part to be paid by the tradesman, and it will be economical as well in reducing their outlay for seeds and sundries and setting them free to buy in the best markets. *East Herts. (employer).*

THE GOOSEBERRY SCARE.—Before we make up our minds to take Mr. Salmon's advice and ask the Government to stop the importation of Gooseberry plants, it would be just as well if we ascertained if any one in this country does import them. It would be bringing coals to Newcastle, that is quite certain, as the best sorts are of English origin and they are so easily propagated that our nurserymen can supply them at about 25s. per 100 and make a profit out of them at that price. I have some knowledge of the nursery trade, but I have never yet met with imported Gooseberry plants. Then what have our nurserymen, such as Messrs. Bunyard, Veitch, Low, Clibran, Cannell, &c., to say respecting Ribes aureum as a possible source of contamination? It is said to be used as a stock for standard Gooseberries. Do these growers employ it for that purpose? I have heard of a case in which some Gooseberries that had been worked on Ribes aureum failed in this country, probably because they didn't like the stock. The questions are: do we import Gooseberry plants and who uses Ribes aureum as a stock? *W. [The answer in both cases is yes.—Ed.]*

ROSES IN POTS.—The following method of cultivating Roses in pots may be of interest. It is practised in a large market nursery, where pot Roses are a speciality. In the early autumn seedling Briars with stems about the thickness of a pencil are trimmed at their roots and potted into 60-size pots. They are stood in a frame, or plunged into ashes in the open, until they are required for grafting about the second week in January. The stems are then severed to within an inch of the soil with a sharp oblique cut, and grafted with short pieces of wood having three or four buds of the varieties required. The scion should be about the same thickness as the stock, and, when united, bound together with worsted or soft twine, and finished with a little grafting wax. They should then be plunged in a propagating case or house having a temperature of 70°, and be slightly syringed twice a day. In a month or six weeks the scion and the stock will have united, and the buds will have developed into growth. They should then be gradually hardened off, and in a period of about two months from the time of grafting, they should be ready for shifting into 48-sized pots, using a similar compost to that recommended by Mr. Clarke. They may then be placed in a frame until June, when they should be potted into 24 or 16-inch pots—according to the amount of growth they have made—and stood out in the open. If they receive careful attention, they will produce a few flowers late in the following spring, in a cool house, and in less than two years from the time of grafting they will be magnificent plants for forcing purposes. Amongst the best varieties for this method of culture are Bridesmaid, The Bride, Niphetos, Liberty, Safrano, Perle des Jardins, Sunrise, and Catherine Mermet. *Chas. Vines, Loudwater Gardens, Rickmansworth.*

—Mr. W. H. Clarke's article on "Roses in Pots," p. 36, recalls to mind the excellent pot Roses grown by the late Mr. H. Marslen, when manager at the Isleworth branch of Messrs. Charles Lee and Son's famous nursery. A considerable number of Roses were cultivated as advised by Mr. Clarke, and with most satisfactory results. Indeed better plants than these I have not seen since. Maréchal Niel was especially well grown, and strong, healthy, well-ripened growths of this Rose were 10 and 12 feet in length, the result of one season's development. Mr. Marslen was an excellent propagator and cultivator of all hard-wooded plants. *C. Ruse, Munden Gardens, Watford.*

TAR AS AN INSECTICIDE.—I can endorse the statement made by Mr. J. Willis, p. 45, respecting tar as an insecticide, having for some time used it as a winter dressing for vines, &c. The thorough mixing and boiling of the components in their correct proportions I consider to be the secret of success. We use it prepared as follows:—To one gallon of finely-sifted, dry soil, add half-a-pint of pure gas tar (tar varnish should not be used); mix this in an iron pot, and place over a steady fire, adding boiling water sufficient to bring it to the consistency of paint. When cool, the mixture is ready for use. *C. Ruse, Munden Gardens, Watford.*

—On taking charge of these gardens four years ago, I found the Black Hamburg winery was simply smothered from end to end with mealy bug, also the Muscat house adjoining had a fair proportion. The late house, fortunately, was clean, but, according to my employer, the old rods had been dressed with a very strong insecticide, most probably petroleum, and this had killed every rod in the house. In the other houses I had thirty-year-old rods, with spurs 9 inches to a foot long, to deal with. After pruning the vines I washed each rod with strong soda-water, and dressed them with a mixture of one part gas-tar to nine parts of clay. I thoroughly baked the clay and crushed it into powder. I then poured the tar on to the clay and mixed them well together. I afterwards added enough boiling water to make it of the consistency of paint, and applied the mixture when cold with an old paint brush to all parts of the rod except the "eyes." I have used this every year, and found it very effectual and safe. Our vines are practically free from mealy bug. I adopted this remedy after seeing it described in the *Gardeners' Chronicle* some four or five years ago. *J. A. Huntley, The Gardens, Oak Hall, Buckhurst Hill.*

THE USES OF TAR ON TREES.—I have used tar on trees for canker for a number of years past with the best possible results, both Stockholm and gas tar; the latter is the best. I put it on the affected parts with a small brush. The bark grows to its original state, pushing off the rough parts on which has been the canker, with the tar attached. I have also used it on Grape vines over a large cut to ensure safety from bleeding (painters' knotting also is a good remedy for this if done directly a cut is made). I have never used tar as an insecticide on plants, but, like many other gardeners, think that it would be well to use the valuable space offered in the *Gardeners' Chronicle* for discussion of the subject. *John Beams, Kensington and Chelsea Schools, Banstead, Surrey.*

BRAMBLE HYBRIDS.—In his interesting description of Raspberries and Brambles, p. 38, Mr. Baker refers to the Parsley-leaved Bramble as a distinct species, yet regards it as being merely a cut-leaved form of Rubus Selmeri, a common British Bramble. If that be so, is it correct to describe Rubus laciniatus as a species? We have no Bramble more widely grown in gardens or more generally known than is this one, yet up to the present time no one seems to know its origin. Mr. Baker seems able only to conjecture. Certainly, whilst it has all the hardy qualities of the British Bramble, and is in that respect much superior to any of the earlier American varieties, yet its fruits are finer and produced much earlier than those of any known British variety or species. It seems odd, assuming that the Parsley-leaved form started from some British species, that similar sorts have not been recorded. Mr. Baker's list seems chiefly restricted to American Brambles. That being so necessarily omits the interesting Rubus phœnicolasius—the Japanese Wineberry—yet this species is a common denizen of British gardens; that is, no doubt, a defined species. Our chief British Bramble Hybrid is Messrs. Jas. Veitch and Sons' "The Mahdi," one of Mr. Seden's "creations," a variety happily having no botanical name, that merits a place in all gardens, for its fine blood-red fruits are sweet and richly flavoured, following immediately on the Raspberry in ripening. Possibly next autumn the public may be permitted to see fruit of another of these Bramble Hybrids that is also red in colour, but double the size of any other similar fruit yet known. Brambles are now almost essential fruits in gardens, and what with the Parsley-leaved, the Loganberry, the Mahdi, and the Japanese Wineberry, there is a good selection wherewith to stock a special Bramble quarter. *A. D.*

BEGONIA GLOIRE DE LORRAINE.—We have plants of this Begonia growing in three plant-houses in these gardens, and I find seed-pods on plants in each house. In house No. 1, which is rather lofty, they are stood on an open stage, the night temperature in the structure being about 55°. The plants in house No. 2, which is a low-roofed Melon house, are standing on fine gravel, and here the night temperature is about 60°. House No. 3 is a low Cucumber pit, in which Cucumbers are still fruiting, the Begonias being stood on ashes. A night temperature of 70° is maintained in this building. All the plants are syringed on fine days, and they have done remarkably well this year, especially those grown on the ash bottom in the Cucumber house. They are potted in a compost of equal parts—loam, peat, and half-decayed leaf mould—with a little sand added. I notice that in every plant the seed-pod is developed from the terminal flowers, which are usually cut away as soon as the plants become a little untidy, and thus they are not allowed to develop, which may account for their being so rarely seen; and I am of opinion that if the plants are kept long enough, many of them will seed at their extreme flowering points. Our specimens have had no feeding after they were potted, but plenty of soft, pond water. I find they do not like hard water at any time. *R. Lewis, The Gardens, Bystock, Exmouth, Devon.*

SOCIETIES.

ROYAL HORTICULTURAL.

JANUARY 22.—At the ordinary meeting of the Committees held on Tuesday last the display was of moderate extent, and Orchids were the chief feature. The ORCHID COMMITTEE recommended five Awards of Merit to novelties, two of which were sent by M. VUYLSTEKE, Loochristy, near Ghent. The FLORAL COMMITTEE had but one plant up for inspection, and, like the FRUIT & VEGETABLE COMMITTEE, did not make any award to a novelty. In the afternoon 50 new Fellows were elected, and a lecture was read on "Some Aspects of Fruit-growing in Japan" by Mr. N. Matsui, Director of Agriculture in Tokio.

Floral Committee.

Present: H. B. May, Esq. (in the chair), and Messrs. C. T. Drury, R. C. Notcutt, Jno. Green, T. W. Turner, G. Reuthe, C. J. Salter, C. Dixon, H. J. Cutbush, C. E. Shea, J. T. Bennett-Poë, E. H. Jenkins, W. J. James, Jno. Jennings, W. Cuthbertson, J. Douglas, W. Howe, C. R. Fielder, R. Hooper Pearson, Rev. F. Page-Roberts, George Gordon, R. W. Wallace, James Hudson, and Edward Mawley.

Messrs. WM. CUTBUSH & SONS, Highgate Nurseries, London, N., staged a very handsome group of flowering plants from retarded stock of such subjects as *Lilium*, including *L. lancifolium* and its white variety; *L. auratum*, &c.; *Lily of the Valley*, *Azaleas*, *Astilbe* (*Spiraea*) *japonica*, &c. Much of this group was also occupied by heavily-fruited plants of *Citrus japonica*. On an adjoining table the same firm had a goodly display of winter-flowering Carnations, all admirably grown, and a representation of a rock-garden furnished with early-flowering Alpines and dwarf shrubs. This last-named exhibit was very rich in bulbous Irises, *I. Danfordi* (yellow) being especially pleasing. We may also mention *I. stylosa*, *I. histrioides*, and a hybrid, *I. x sind-per*, a cross between *I. sindjarensis* and *I. persica*, with flowers of the clear shade of colour known as Cambridge blue. (Silver-Gilt Banksian Medal.)

Messrs. JAMES VEITCH & SONS, Ltd., King's Road, Chelsea, S.W., staged a group of spring-flowering shrubs in a setting of *Eurya latifolia*, and with plants of *Phyllostachys* as a background. Species of *Hamamelis* shown included *arborea*, *mollis* and *Zuccariniana*. A touch of colour was furnished by a row of *Rhododendron* Early Gem, and these were overshadowed by taller plants of *Magnolia stellata*, while in the centre of the group were specimens of the new *Buddleia asiatica*. Messrs. VEITCH also displayed a finely-flowered batch of *Eupatorium vernale*, a useful greenhouse subject for winter flowering, interspersed with *Jacobinia chrysostephana*, and the taller *J. coccinea*. (Silver Flora Medal.)

Mr. H. B. MAY, Dyson's Lane Nurseries, Upper Edmonton, again exhibited stove and greenhouse Ferns in variety, and plants of *Primula obconica* that had been specially selected for their shades of colouring and large inflorescences. The Ferns included rare and beautiful species and varieties, all of which were shown in the best cultural condition. The collection was especially rich in *Platyteriums*. (Silver Flora Medal.)

Mr. L. R. RUSSELL, Richmond Nurseries, Richmond, Surrey, displayed ornamental shrubs and small Conifers. Many of the shrubs were in flower, others in berry, and some were shown for their pleasing foliage. *Daphnes*, *Eleagnus*, *Ivies*, *Bamboos*, *Ericas*, *Hamamelis*, and *Euonymus* formed the principal subjects.

G. F. RAPHAEL, Esq., Porter's Park, Shenley (gr. Mr. A. Grubb), showed large blooms of *Souvenir de la Malmaison* Carnations in glass vases amidst a setting of trails of *Asparagus Sprengeri*. The colour in the flowers was finely developed, and the blooms were very large. (Bronze Flora Medal.)

Messrs. SUTTON & SONS, Reading, displayed a large number of plants of their excellent strain of *Cyclamen*, in shades of the most pleasing colours that ranged from pure white to dark purple. Especially noticeable were those of a salmon shade, their "Salmon Queen" being an excellent variety. Some of the flowers showed frilled margins in the petals—the so-called fimbriated type. (Silver Banksian Medal.)

Messrs. HUGH LOW & CO., Bush Hill Park Nurseries, Enfield, N., showed some well-flowered plants of *Cyclamen* of a good strain. This firm also exhibited admirable Carnations, among which was a sport from the well-known variety Mrs. T. W. Lawson, with petals of a very delicate shade of salmon. They also showed a handsome *Nephrolepis* named *Wietmanni*, much resembling the beautiful *N. todeoides*; plants of *Daphne indica rubra*, *Euphorbia jacquiniiflora*, &c. (Silver Banksian Medal.)

Mr. G. LANGE, Hampton, Middlesex, showed American varieties of Carnations in popular kinds. The new *White Perfection* is a very choice flower, which may be described as an improved *Bountiful*. It was admirably shown in this group. (Silver Banksian Medal.)

Messrs. BARR & SONS, King Street, Covent Garden, London, W.C., showed a few interesting Alpines in flower, and bowls of bulbous plants—*Crocus*, *Galanthus Elwesii*, *Narcissus Tazetta*, *N. Bulbocodium*, &c. Heavily-flowered sprays of *Jasminum nudiflorum* overhung from the background of the group.

Mr. G. REUTHE, Hardy Plant Nurseries, Keston, Kent, also showed a selection of early-flowering rock-garden plants. We noticed the recently-introduced *Hamamelis mollis*, *Damnacanthus indicus*, *Lomatia pinnatifolia*, a very stately plant by reason of its handsome foliage; *Primula megasefolia*, and the hardy *Daphne japonica*.

Collections of Alpine plants were also shown by Messrs. JOHN PEED & SON, West Norwood, and the Misses HOPKINS, Hillside Nurseries, Barming, near Maidstone, Kent.

Some well-executed paintings in oils of floral subjects were displayed by Mrs. SOPHIA MILLER, 1, Campden Hill Road, Kensington. (Silver Banksian Medal.)

Orchid Committee.

Present: J. Gurney Fowler, Esq. (in the chair), and Messrs. Jas. O'Brien (hon. sec.), Harry J. Veitch, De B. Crawshaw, Francis Wellesley, J. Wilson Potter, W. A. Binley, H. A. Tracy, W. H. White, H. G. Alexander, W. H. Young, H. J. Chapman, H. G. Morris, J. W. Odell, A. Dye, H. T. Pitt, F. M. Ogilvie, G. F. Moore, T. W. Bond, A. A. McBean, F. Sander, W. Boxall, H. Little, Jeremiah Colman, and J. Charlesworth.

Major G. L. HOLFORD, C.I.E., C.V.O., Westonsbirt, Tetbury (gr. Mr. H. G. Alexander), staged a beautiful display of cut spikes of white varieties of *Lælia anceps*, in all about 150 blooms on 60 graceful spikes, including *Schroderiana*, *Stella*, *Sanderiana*, and *Ashworthiana*. In the front was a grand specimen of *Cattleya Percivaliana*, with 26 finely-coloured flowers, and with it were the new *Cypripedium Moloch* (*Charlesworthii* x *Euryades*), with a peculiar dorsal sepal of a purple colour, and tipped with white; and the orange-coloured

Lælio-Cattleya "Ariel" (*Cowani* x *saura*). (Silver Flora Medal.)

F. DU CANE GODMAN, Esq., South Lodge, Horsham, staged a group of splendidly-grown and finely-flowered varieties of *Lycaste Skinneri*, and including a specimen of the pure white form with nine flowers, each plant bearing many large flowers of excellent quality. At each end of the group were grand specimens of *Maxillaria grandiflora*, which secured an Award of Merit and Cultural Commendation, the group receiving a Silver Flora Medal.

Messrs. JAS. CYPHER & SON, Cheltenham, staged an effective group of *Cypripediums*, *Lælia anceps* varieties, *Odontoglossums*, &c. Among the more notable were *Cypripedium Charlesianum*, "Cypher's variety," a very large and fine flower; *C. Minos*, "Young's variety;" *C. Madame Jules Hye*, *C. vill.-exul*; a very fine dark from *C. Harrisianum*; *C. George Moore* (*Sallieri* x *Mrs. Wm. Mostyn*), a grand flower; and several other new hybrids, &c. (Silver Flora Medal.)

Messrs. CHARLESWORTH & CO., Heaton, Bradford, staged a fine group, principally hybrids, among which were several specimens of their beautiful form of *Cattleya Octave Doin*. Others noted were the fine white *Brasso-Cattleya Queen Alexandra*; a brightly-coloured *Lælio-Cattleya illustre*, and other showy *Lælio-Cattleyas*; the rare *Selenipedium Saundersianum*, with dark-reddish rose-coloured flowers; *Cypripedium exul-concolor*, bearing ivory-white flowers, marked with purple spots; a goodly selection of hybrid *Odontoglossums*, including their fine type of *O. Rolfæ*, *O. Elaine* (*cirrosium* x *Harry-anum*), and some unnamed hybrids. The species and varieties included *Odontoglossum crispum*, with two spotted forms; in the centre of the group were two very fine plants of *Vanda Amesiana*, each bearing nine very strong, branched flower-spikes. (Silver Flora Medal.)

Messrs. SANDER & SONS, St. Albans, exhibited a very varied group of good things, in the centre being a fine plant of the rich, purplish-rose *Brasso-Cattleya Madame Chas. Maron*, with eight flowers, and the fine, large, white *Brasso-Cattleya Madame Fournier alba*. The group also contained a nicely-flowered, spotted *Odontoglossum* (*crispum* x *loochristense*), *Zygopetalum Gottianum*, with purple petals and dark violet lip; the very pretty and rare *Odontonia Laireseæ*, with a fine branched inflorescence; *Cattleya Trianae* "Blue Gown," with flowers of a decided blue tint; *Cypripedium Hitchinsiae vivicans*, having large blotches of a dark rose shade on its white, dorsal sepal; the new white *Vanda Watsoni*; a batch of *Epidendrum Wallisii* raised from seed, and a number of rare *Cypripediums*, &c. (Silver Flora Medal.)

Monsieur CHARLES VUYLSTEKE, Loochristy, Ghent, staged new and rare hybrid *Odontoglossums*, two of which secured awards. The others included varieties of the richly-coloured *Odontoglossum Vuykstekei* *O. percultum*, *O. ardentissimum*, &c.; a good specimen of *Cymbidium Holfordianum*, and one nicely-spotted plant of *O. crispum* named *Talma*. (Silver Flora Medal.)

Messrs. JAS. VEITCH & SONS, Chelsea, staged an effective group of Orchids, three special plants in which were the singular and pretty *Phalaenopsis* Mrs. J. H. Veitch (*Luddemania* x *Sanderiana*), a variety having yellowish flowers spotted with purple, and a white lip with a few purple markings at the base; *Cypripedium Countess of Carnarvon* (*villosum giganteum* x *Euryades*), a finely-formed flower, the white, dorsal sepal being blotched with purple and coloured emerald green at the base, &c. (Silver Banksian Medal.)

G. SINGER, Esq., Coundon Court, Coventry (gr. Mr. Collyer), staged a small group, in which were cut spikes of *Phalaenopsis intermedia*, and its variety *Brymeriana*; *P. Lady Rothschild* (*intermedia* x *Sanderiana*); varieties of *Cattleya Trianae*, *Cypripedium aureum* *Surprise*, &c. (Silver Banksian Medal.)

FRANCIS WELLESLEY, Esq., Westfield, Woking (gr. Mr. Hopkins), showed *Cypripedium Tautianum nigricans* (see Awards); *C. Euryades* "Miss Edith O'Reilly," a pretty flower with the large, white, dorsal sepal bearing rows of purple spots, and yellow petals veined with purple, and lip tinged with the same colour; *C. Cassandra*, "Westfield variety," a fine improvement on *C. callosum*, one of its parents; and *Brasso-Lælia Westfieldiensis* (*B. glauca* x *L. flava*, of neat habit of growth, and bearing

white flowers with a faint green tinge on the sepals, the lip being crimped and three-lobed.

W. THOMPSON, Esq., Walton Grange, Stone, Stafford (gr. Mr. Stevens), sent *Odontoglossum Thompsonianum* (Edwardii $\times$ crispum), for which he was awarded a First-Class Certificate on April 25, 1905. The flowers are claret-coloured with a rose margin, and tips of the segments of the same colour; the crest is yellow.

Messrs. J. McBEAN & SON, Cooksbridge, staged a small group of Orchids, which included several noble forms of *Odontoglossum crispum*, a very handsome and distinct *O. loochristiense* of a bright yellow colour and uniformly blotched with chocolate brown, varieties of *Lælia anceps*, *Epiphronitis Veitchii*, two good plants of the white type of *Cymbidium eburneum*, *Oncidium serratum*, *Lælia autumnalis alba*, &c. (Silver Banksian Medal.)

NORMAN C. COOKSON, Esq., Oakwood, Wylam (gr. Mr. H. J. Chapman), showed a grand specimen of *Cypripedium Lceanum* Clinkaberryanum (for which a Cultural Commendation was voted), *Odontoglossum crispum* Theodore Pauwels (a well-formed, heavily blotched flower), the new *Cattleya Chapmanii* (Hardyana Oakwood var. $\times$ Trianae), with dark rose sepals and petals and with a purplish-crimson lip that is veined with gold at the base; *Calanthe Sybil*, a good, pure white variety; *C. Phoebe*, of a soft pink shade; *C. Gildeni*, a large, purplish-rose flower with a claret-coloured lip; *Cypripedium Mary Amelia* (bellatulum $\times$ Lord Derby); and a fine white form of *Cypripedium Orion* var. *bellum*.

Messrs. ARMSTRONG & BROWN, Tunbridge Wells, staged a small group of good and finely-grown *Cypripediums*, which included *C. Minos*, "Young's variety," *C. Fascinator*, *C. Fairrieanum purpuratum*, *C. insigne Berryanum*, *C. Queen of Yellows* (insigne *Sanderæ* $\times$ *villosum aureum*), a large and distinct flower, and other pretty hybrids. (Silver Banksian Medal.)

Mr. F. C. YOUNG, St. Albans, sent a group of hybrid *Cypripediums*, in which were *C. Cligiganteum*, *C. Tityus*, and a brighter hybrid named *C. Madame Lloyd* (*Tityus* $\times$ *Calypso*), varieties of *C. Actæus*, &c. (Silver Banksian Medal.)

Mr. SADLER, Beedon, Newbury, showed *Cypripedium* Mad. Jules Hye, var. *grandis*, a large and finely-formed flower with a good dorsal sepal.

Messrs. HEATH & SON, Cheltenham, staged a group of *Cypripediums*, *Odontoglossum Andersonianum* and *O. crispum*.

Messrs. HUGH LOW & CO., Enfield, arranged a group in which were *Cypripedium Olivia*, *C. Ville de Paris*, a massive and well-marked flower; *C. Sallieri Hyeum*, *C. Minos*, "Low's variety," *C. Thompsoni*, *C. Maudiae*, a distinct dark hybrid between *C. ciliolare* and *C. Chamberlainianum*; *Spathoglottis Lobbii*, *Platyclinis glumacea*, &c.

H. T. PITT, Esq. (gr. Mr. Thurgood), showed *Lycaste Balliæ* Rosslyn var.

Monsieur MERTENS, Ghent, showed a blue-tinted variety of *Cattleya Trianae*, *Cypripedium aureum Hyeum* and *virginale*, *Miltonia Bleuana grandiflora*, &c.

Messrs. J. W. MOORE, Ltd., Rawdon, Leeds, showed hybrid *Cypripediums*.

MALCOLM S. GOOKE, Esq., Kingston Hill (gr. Mr. Buckell), sent an *Odontoglossum crispum* with a branched spike.

R. I. MEASURES, Esq. (gr. Mr. Smith), sent *Cypripedium Buchananianum magnificum* and *Masdevallia melanopus*.

Mr. ROBSON, Altrincham, showed *Cypripedium* Mrs. Robson (*Actæus Langleyense* $\times$ *insigne* Harefield Hall), a model flower with a circular dorsal sepal, green spotted with brown and with white upper part; *C. Thompsoni*, with six flowers; and *C. aureum* var.

JEREMIAH COLMAN, Esq., Gatton Park (gr. Mr. Bound), sent *Cattleya Miranda*, Gatton Park variety, a pretty rose-tinted form with purplish front to the lip, which is more tubular than in other varieties.

AWARDS OF MERIT.

Cypripedium Tautianum nigricans from FRANCIS WELLESLEY, Esq., Westfield, Woking. A most remarkable variation from the light-coloured type, the dorsal sepal being ruby-red, with a slight white margin and dark claret lines. Petals reddish rose, profusely spotted with chocolate-purple; lip, claret coloured.

Odontoglossum caloglossum (crispum $\times$ *Vuytstekei*) from M. CHAS. VUYLSTEKE, Loochristy, Ghent. One of the finest hybrid *Odontoglossums* in size, shape and colour, the flower being large, broad in all its parts, and very richly coloured. Sepals and petals nearly covered with fine reddish claret blotches, the margins, tips, and thin spaces between the blotches being lighter. Lip white with a yellow crest, in front of which are some large dark rose blotches, then a band of white, followed by smaller spots.

Odontoglossum Ruby from M. CHAS. VUYLSTEKE. A showy hybrid of unknown parentage, the inner two-thirds of the segments being heavily blotched with claret colour, the outer third pale lilac. Lip white, with purplish blotches.

Lælia anceps Schrodera "Grace Ruby" from Messrs. McBEAN, Cooksbridge. A very fine flower, near to the handsome *L. a. S. Theodora*. Flowers white, brightly tinted with magenta crimson, especially on the petals; side lobes, and broad front lobe of the lip deep maroon colour.

Maxillaria grandiflora from F. DU CANE GODMAN, Esq. The fine species allied to *M. venusta* and bearing large white flowers.

Fruit and Vegetable Committee.

Present: Mr. Joseph Cheal (in the chair); and Messrs. W. Bates, S. Mortimer, A. Dean, Ed. Beckett, G. Kelf, H. J. Wright, W. Barnes, H. Markham, Jas. Vert, Jos. Davis, Geo. Reynolds, P. C. M. Veitch, C. G. A. Nix, A. D. Tuckett, J. Jaques, Chas. Foster, Owen Thomas, and H. Parr.

Only one collection of fruit was staged, but this was of exceptional quality, and it is only on rare occasions that produce of such excellence is seen so late in January. It was shown by the Rt. Hon. Earl STANHOPE, Chevening Park, Sevenoaks (gr. Mr. J. C. Sutton), and consisted of Grapes and about two dozen dishes and baskets of Apples. The latter fruits were plump and splendidly coloured. The varieties included Baumann's Red Winter Reinette, Woodstock Pippin, Easter Orange, King's Acre Pippin, Tower of Glamis, Blenheim Pippin, Prince Arthur, Royal Jubilee (with a beautiful deep yellow exterior), and a basket of that grand late-keeping Apple, Annie Elizabeth, shown under the name of Minchull Crab. The Grapes were also splendidly finished, the varieties being Lady Downes, Gros Guillaume, and Black Alicante. (Silver-Gilt Banksian Medal.)

Messrs. CANNELL & SONS, Swanley, Kent, showed three dozen very large, solid Onions, having the varieties Ailsa Craig, Cocoonut, and the Giant in about equal numbers. (Cultural Commendation.)

FRUIT GROWING IN JAPAN.

The Rev. W. Wilks read in the afternoon a paper furnished by the Imperial Japanese Department of Agriculture on "Modes of Pruning and Training Fruit Trees in Japan, and Routine Operations in Japanese Orchards." It appears, from the statements made by the writer of the paper, that the ordinary details of fruit culture were not so well practised in Japan as in European countries, the Japanese often preferring the blossoms to the fruit. The prevalent form of fruit training is restricted to the "table cordons" of the West, for such kinds as bear on spurs, as well as for vines. It is not uncommon in Japanese orchards to find that Pears, Date-Plums (*Diospyros kaki*), Chestnuts, and Citrus fruit trees have the habit of fruiting in alternate years, and growers believe that such a state of things is not to be changed by human interference. The system of training—on a horizontal trellis of bamboo canes on wooden posts—is widely used because of convenience of management, harvesting, and the control of insect enemies, the simplicity and durability of construction, and the securing of the maximum surface to enjoy the full sunshine on the tree. Kaki, the Persimmon, has been the most widely cultivated fruit, but of late years more attention has been given to the Peach.

The process of placing bags over the fruit has been extensively adopted by Japanese growers as a preventive measure against insects and fungi; and in South Japan, where Peaches, Pears, and Grapes are largely grown, bottomless bags made of newspapers are widely used. The time of bagging varies for different fruits; in the case

of Peaches the work of bagging is begun at the time the fruit reaches the size of ripe Cherries. In order to prevent the access of mildew, the bags are smeared on the inside with a preparation of sulphur. As to irrigation, the damp climate of Japan greatly reduces the necessity of irrigation in summer. The use of salt as a manure was advocated in certain cases.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

JAN. 10th.—Committee present: E. Ashworth, Esq. (chairman), and Messrs. Sander, Rogers, Williamson, Shill, Ward, Keeling, Ashton, Cypher, Parker, R. Ashworth, Ritchie, Thompson, Thorp, P. Smith. There was a capital display of plants at this meeting. A group of plants was staged by W. THOMPSON, Esq., Stone, in which was included the very distinct *Odontoglossum* $\times$ *Thompsoni*, which was awarded a First-Class Certificate last year. On this occasion the plant shown was better than when the certificate was granted, and it may be considered one of the best *Odontoglossum* hybrids.

A. WARBURTON, Esq., Haslingden, also staged a group of Orchids, in which *Odontoglossum crispum* var. "Flora Marguerite" was the most notable feature. This plant is a seedling raised from two well-known varieties of *Odontoglossum crispum*. (Silver Medal.)

Messrs. CYPHER & SONS, Cheltenham, and Messrs. CHARLESWORTH & CO., Bradford, were each awarded Silver Medals for groups. Bronze Medals were awarded to WALTER LAVERTON, Esq., Nantwich, Messrs. J. W. MOORE, Ltd., Bradford, and Messrs. KEELING & SONS, Bingley, Yorks., for groups. Mr. J. F. SADLER, Beedon, Berks, was given a vote of thanks for a group of Orchids.

Awards of Merit were granted to *Cypripedium insigne* var. *Mars*, *C. i.* var. *Eileen*, *C. x Hitchensæ* var. *Babette*, *C. x H.* var. *stumpendum*, *C. x H.* var. *Thompsonianum*, *C. x aureum* var. *delicatum*, *C. x Alcibiades* var. *superbum*, *C. x "Violet Arkle"*, *Odontoglossum x Lambauium*, Thompson's var., all shown by W. THOMPSON, Esq., Stone; *C. x Venus*, Craven's var., shown by J. H. CRAVEN, Esq., Keighley; *Odontoglossum crispum* var. *Flora Marguerite*, shown by A. WARBURTON, Esq., Haslingden; and *Cyp. x Transvaal* var. *superbum*, shown by O. O. WRIGLEY, Esq., Bury. P. W.

SOCIÉTÉ FRANÇAISE D'HORTICULTURE DE LONDRES. ANNUAL DINNER.

JANUARY 19.—Founded about 18 years ago by Mr. George Schneider, who still continues to fill the office of president, the French Society of Horticulture in London makes new friends every year. This circumstance explains the fact of there being many gentlemen present at the annual dinner, on January 19, who are not counted among the *membres titulaires*. The event took place at the Café Royal, Regent Street, under the presidency of Monsieur F. Lageat, and the guests numbered about 70 persons.

The first toast was that of "Le Président de la République," which was followed by the singing of the "Marseillaise," and after the toast of "The King and Royal Family" a verse of the National Anthem was also sung.

These pleasant preliminaries over, the chairman, speaking in French, proposed "La Société Française d'Horticulture de Londres." In doing so he said he wished to give to the younger members a little advice which might be summed up in the two words *Travail et Volonté*. The society was not lacking in examples of what can be accomplished by stubborn work and indomitable will. He could not refrain from mentioning the most striking instance. One of their honorary presidents, M. Ouvrard, who was not able to attend that function, was probably the first Frenchman to establish himself in England as a horticulturist. This happened more than 50 years ago. M. Ouvrard had succeeded mainly by hard work and the exercise of a will of iron. During more than 40 years he never failed to attend the Covent Garden market, and yet had also occupied himself during the same period in the carrying out of the practical work of the nursery. This experience was sufficient to prove that "work does not kill." M. Ouvrard is 88 years of age, but is nevertheless in good health,

and capable of exercising all his faculties. The chairman besought his hearers to imitate M. Ouvrard, and put into practice the English saying, "Where there is a will there is a way." Passing to a consideration of the subject of horticulture in France, the chairman said that the art was always greatly honoured there, and extensively practised. Doubtless the favourable character of the soil and climate had much to do with this. "*Aller planter ses choux*" was there a favourite manner of describing the retirement of a man from his business pursuits to a period of leisure, usually spent in the country rather than the towns. The whole of Europe was, more or less, dependent on France for some product of horticulture. There was, however, a shadow to this flattering picture. Every year France exports fewer Apples than previously, and unless French cultivators awake to the position, the exports will in course of time cease altogether. Northern America, by cultivating varieties more agreeable to the taste of the consumers, had nearly captured the English market, to which she imported in 1905 Apples to the value of more than 25,000,000 francs. She was also establishing a good connection in Germany, and during the past two years had sent Apples even to the Paris market itself. This was a painful situation, and he asked the younger members especially to find a remedy for it.

If France excels in out-door gardening, however, said the chairman, Frenchmen would freely admit the superior skill of Englishmen as cultivators under glass. Few large forcing nurseries existed in France, but in England they are numerous. There was, therefore, much for them to learn during their short stay in the United Kingdom, and he hoped they would continue to come here in large numbers. The aim and end of the society was to assist its members to acquire knowledge, and to bring them into companionship with each other during their absence from their own country. It included honorary and *titulaire* (effective) members. These latter were French, Belgian or Swiss, or even of other nationalities provided the individuals could speak the French language. A member may become a life member on paying a sum of £1. In 1898 the reserve fund amounted to £28 4s. 11d., and it was now £178 15s.; prosperity was also indicated by the increased number of members. He strongly urged the members to make all the use possible of the society's library and of the monthly meetings.

M. F. Lagat concluded by referring to some of the past chairmen at their banquets—Messrs. T. Bevan, J. Cutbush, Moss, Payne, Geoffray (French Minister in London), Geo. Nicholson, Percy Waterer, J. Harrison, and M. Philippe de Vilmorin. He coupled with the toast the name of Mr. Schneider, whose zeal and sympathy on behalf of the society naturally led the members to look up to him as they would to a father. The toast was received with musical honours.

Mr. Schneider, commencing his speech in French, thanked the chairman for his encouraging speech and gave some further particulars respecting the satisfactory financial condition of the society. The library was growing in importance each year and more members make use of it, but it was a matter for regret that they had not a better building for its accommodation. The room at present available was very inadequate. This subject was the only one in connection with the present condition of the society for which he felt regret. Then, "dropping" into English, Mr. Schneider said one of the greatest advantages members might derive from the institution was the knowledge it was possible for them to obtain from members disseminated over all the globe. M. Louis Gentil (Brussels), Drouot (Congo), Marchand (Colombia), Suja (Madagascar), Foukouba (Japan), Scalarandis (Italy), Kitschounoff (Russia), Griessen (India), Guillochon (Tunis), were all linked with the present members and would inform them of the condition of horticulture in these respective countries. The society would also be pleased to assist in placing young Englishmen in French nurseries and gardens (see column 3). After enumerating the names of new members, honorary members, and life members, Mr. Schneider concluded by proposing the toast "*a l'Horticulture Anglaise*." The response was by Mr. J. Gaskill (Messrs Cooper, Tabor & Co.), who also proposed the toast of the "Past Chairmen." Mr. C. Harman Payne, in responding in French to this latter subject, said much water had passed under London Bridge since he presided at the seventh annual banquet. In the course of a humorous speech he said that as the members of their society

were Frenchmen, he would not recommend them courage, but he would counsel them to nurture prudence as an absolutely essential quality if they were to be successful. He concluded by proposing the toast "*Au Bureau de la Société*." This was responded to by M. P. Aquatins, who also proposed the toast "*a la Presse*," coupling this with the name of Mr. R. Hooper Pearson (*Gardeners' Chronicle*), who, in the course of his remarks, said that the society having representatives in so many parts of the globe, was in some degree in the same happy position as the Kew Guild. Mr. Geo. Gordon, V.M.H., and Prof. A. P. Huguenet, Editor of *La Chronique* (London), also made a few remarks. Subsequently, the younger members of the society made a presentation to Mr. George Schneider in thankfulness for his kindness to them.

NATIONAL POTATO.

JANUARY 22.—The adjourned annual meeting of this society was held at the Hotel Winsor, Westminster, on Tuesday last. Mr. George Gordon, V.M.H., presided, and there were eleven members present.

An amended draft of the report was presented by the committee, and there being nothing in this which committed the society to any programme for 1907, the opposition which carried the resolution at the previous meeting was satisfied.

THE REPORT.

The Trials.—An important part of the society's operations during the year has been the conduct of the trials of novelties and older varieties. The committee have been extremely fortunate in having the experienced and practical aid of Professor T. H. Middleton and Mr. H. Henshaw in the carrying out of the chief trials at the Cambridge University Farm at Impington. This season there have been trials of seedlings and novelties. The major section was devoted to novelties which are ready to be placed on the market, and the minor to seedlings which have not yet reached that stage. Altogether there were 22 varieties entered. The full tables of the results are published in the society's "Year Book," but the yields of the minor section will only be notified to the owners. The members of the society who visited the trial ground in August were able to form a high opinion of the value of these trials, and to realise the thoroughness with which they were conducted, whilst the unremitting care taken to ensure an accurate record was strikingly manifested. It is a matter for regret that the society in the future will lose the valued assistance of Professor Middleton, carrying out its trials, but the committee feels that the members will all join in their hearty congratulations to him in his new appointment at the Board of Agriculture. It is hoped that the society will be able to make arrangements for a continuance of the useful co-operation of the Department of Agriculture, at Cambridge University, in carrying out its trials of new and other varieties. At many of the County Council centres trials have been continued, and in several instances a repetition has been made of the trials of Potatoes grown at various distances apart. The committee are greatly indebted to the various secretaries for arranging the trials and furnishing the reports, which will be filed for future reference.

The Show.—As an experiment this year the date of the exhibition was fixed to synchronise with the Smithfield Club Show. It has, however, been found that the date was too late in the year to suit southern growers, whilst many of the trade growers found it impossible to exhibit at both shows. This year's show was smaller, therefore, as regards the total number of entries, although members will agree that it was not lacking in its interesting features.

The Year Book.—With a view to providing fuller scope for circulating authoritative information on Potato growing, a "Year Book" has been produced under the editorship of Mr. Horace J. Wright and the Honorary Secretary. Besides the interesting articles from experts, the lucid and informative report of Professor Middleton as to the Impington trials will prove a splendid addition to the existing records.

The Officers.—Owing to pressure of work, Mr. A. D. Hall has been compelled to resign the chairmanship, to the committee's great regret. Another resignation much regretted was that of Mr. W. P. Wright, to whose energy and organising ability we owe the foundation of the society. On the retirement of Mr. Wright, the committee, with a view to lighten the secretarial work, thought it advisable to separate the offices of honorary secretary and treasurer, and they congratulate the society on their having been able to obtain the services of Mr. W. H. Adsett and Mr. Charles Foster in the respective positions.

The financial statement showed a balance of £24 6s. 9d. on the right side.

The Chairman briefly moved the adoption of the report and balance-sheet, which was seconded by Mr. Horace J. Wright, and accepted without discussion.

Following the acceptance of the report, Mr. Walter P. Wright delivered a long speech, in which he explained the reasons that had compelled him for a time to give up the work he had previously done for the society, and declared he had now come forward again to help it out of a difficulty. He discussed the agricultural side of the question, saying that he believed the society could not look to agriculturists supporting its funds in the future, and the committee might expect to see many of them secede from membership. He thought the society could not continue to live unless

its scope was widened. It must be made more horticultural, and he suggested for future discussion that the society be made to embrace other kinds of vegetables. After speaking on the question of immediate policy, Mr. Wright said he was able, on behalf of the authorities of the South-Eastern College at Wye, to invite the society to hold a show there during the present year between August 30 and the middle of September. The authorities would provide the society with free rooms, exhibition hall, &c., and would entertain the officials during its visit. He concluded by moving a resolution to the effect that the annual exhibition of the society shall be held at Wye, Kent. The resolution was seconded by Mr. C. H. Curtis.

Mr. W. Cutbush remarked that Mr. Wright had said that the agricultural trade had deserted the society, and it was just as true that the horticultural trade would also desert it. He had a letter in his pocket from Mr. Arthur Sutton, stating that Messrs. Sutton & Sons would have nothing further to do with the society. He (Mr. Cutbush) could see nothing for the society to do but to wind up. The balance-sheet showed no greater balance than was needed to discharge their liabilities. He declined to share the responsibility of arranging for another exhibition.

Mr. Poad and Mr. Scarlett both described the feeling in Scotland that exists against the society, which Scotch tradesmen thought to be of very little use to them. Upon Mr. Wright's resolution being put to the meeting there were four supporters, and the chairman declared the resolution carried.

The election of officers was then proceeded with as follows:—Sir John Llewelyn, Bart., president; Mr. Geo. Gordon, a vice-president, in addition to the re-election of the other vice-presidents; chairman, Mr. Walter P. Wright; and vice-chairman, Mr. Malden. Various changes were made in the membership of committees.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.—The annual meeting for the election of pensioners is taking place as these pages are going through the press. A report will be published in our next issue.

GARDEN CHANGES.—Mr. C. J. SALTER has resigned his position as gardener at Woodhatch Lodge, Reigate. Those who have visited the gardens of the late Mr. T. B. HAYWOOD, will remember the evidence they afforded in-doors and out-of-doors of excellent cultivation on the part of Mr. SALTER, who we hope will soon secure another situation suitable to his abilities. Mr. GEO. KELF is also relinquishing the charge he has had at South Villa, Regent's Park, London, owing to the recent decease of the proprietress. Mr. KELF has won many medals for good cultivation in London and should be a specially valuable gardener for a gentleman whose garden is surrounded by an atmosphere peculiar to large towns.

THE ROTHAMSTED AGRICULTURAL STATION.—The Rothamsted Experimental Station (Lawes Agricultural Trust) has received a donation of £2,000 from the Permanent Nitrate Committee, to be invested and added to the general endowment fund of the Station. A donation of 100 guineas has also been received from the Fertiliser Manufacturers' Association. During the past summer the Station entered into occupation of the "James Mason" Bacteriological Laboratory, the gift of Mr. J. F. MASON, M.P. The Society for extending the Rothamsted Experiments, which was formed to obtain funds wherewith the Experimental Station might enlarge the scope of its work and initiate further agricultural investigations, has further received during the past year subscriptions and donations amounting to £240. Further subscriptions are still urgently needed to secure a more adequate staff, and may be addressed to the Secretary of the Rothamsted Experimental Station, Harpenden, Hertfordshire.

OPENINGS FOR YOUNG ENGLISH HORTICULTURISTS IN FRANCE.—The following is an extract from a speech delivered by the president, Mr. GEORGE SCHNEIDER, at the annual dinner of the Société Française d'Horticulture de Londres, of which a report appears on this page:—"It should be borne in mind that if it (the Society) helps to place young Frenchmen here, it also places in France any young Englishmen desirous of going there. We are sending a young fellow near Paris, in February, to join those placed last season by the Society. It is true, however, there are not many who avail themselves of the opportunity, but I may safely say that all Englishmen who have made application have been suitably placed by us, and it is satisfactory to state here that these young fellows generally remain connected with our Institution."

Obituary.

DR. WINTER.—John Newnham Winter, M.R.C.S., L.S.A., who died at 18, Lichfield Road, Kew Gardens, at the age of 76, on Friday, January 18, from heart failure following influenza, had the finest private collection of filmy Ferns in this country. He corresponded with Kew and Backhouse's, of York, and imported Ferns himself from the West Indies, New Zealand, and Mauritius. Dr. Winter was, for 40 years, one of the principal medical practitioners in Brighton, and he used to attend to his Ferns himself every morning before beginning his medical work. When he retired from active work he removed to Kew and brought with him his collection of filmy Ferns, and began with characteristic energy to grow Alpine plants. Into the small garden behind his house he brought many tons of rock, so that nearly his whole ground was turned into a series of rockeries. He regularly went to the shows of the Royal Horticultural Society in Vincent Square, and used often to wait until closing time and buy up the plants he wanted and come home laden with treasures. Dr. Winter learnt his Botany when attending lectures by Dr. Lindley in the Chelsea Botanic Gardens. He was a man of remarkable originality and kindness, much beloved by his many patients and friends. The funeral took place at Brighton on Monday, January 21. Edna Lyall, the novelist, was a niece of Dr. Winter's.

T. S. JERROLD.—Mr. Thomas Serle Jerrold, the youngest child and the last surviving son of Douglas Jerrold, died on Sunday last. He studied horticulture under Sir Joseph Paxton at Chatsworth. For many years he was a writer on garden subjects in this and other journals, and was the author of "The Garden that Paid the Rent," "Our Kitchen Garden," and (with his wife, a daughter of Robert Copeland, of Liverpool) "Household Horticulture." Mr. Jerrold, who had lived in Canada for 18 years and returned just over a year ago, leaves four sons and three daughters.

ANSWERS TO CORRESPONDENTS.

AFRICAN RUBBER: *Half a Century Subscriber.* The trees would be *Hevea brasiliensis* (Para rubber) or *Castilloa elastica*. In the Congo State large use is made of various climbing plants, chiefly species of *Landolphia*. See Messrs. De Wilde-man and Gentil's *Lianes Caoutchifères*, to be had from the office of the Congo State, Brussels.

BEDDING PLANTS: *Constant Reader.* To be planted with the *Salvia patens* we should suggest a row of *Aster sinensis* (mauve), then a row of white Stocks alternated with *Phacelia campanularia*, and an edging of dwarf, white *Antirrhinum* alternated with *Alyssum maritimum*. If you have them, pyramid or standard *Heliotropes*, placed about 5 feet apart along the middle of these beds would be effective; failing this, you could sow seed of either *Eucalyptus coccifera* or *E. coriacea*, and use the young plants instead of *Heliotropes*. In the two beds to be backed with white *Marguerites* plant next to these a row of *Godetia* "double rose" alternated with *Lobelia cardinalis*, then scarlet *Salpiglossis* and white bedding *Asters*, edging the bed with dwarf, scarlet *Antirrhinum* alternated with *Chamaepeuce cassabonae*, or if much colour is preferred, substitute scarlet *Begonia semperflorens* for the *Chamaepeuce*. At each end plant a row of large flowered *Mignonette*; the fragrance will be acceptable to persons using the seats. For these beds either of the *Eucalyptus* named may be used as "dot plants." With the exception of *Lobelia cardinalis* the plants named are used as annuals, and if *Lobelia* seed is sown in heat at once, the plants will be large enough to flower this year. As you say you have ample convenience for raising plants, it would be advisable to make several sowings of *Mignonette*, and grow on the plants in pots to replant three or four times during the season. Seeing that the flower beds are in front of groups of shrubs it will be necessary to deeply dig the beds, or the roots from the shrubs will rob the bedding plants. *Salvia patens* and *Lobelia cardinalis* require copious waterings during dry weather.

BUYING ORCHIDS: *W. J. D.* If you can spare the time to attend sales, or have a trustworthy agent to represent you there, you can often purchase the kinds you mention at the sale-rooms

to advantage. Otherwise you should ask for a quotation of prices from the Orchid nurserymen. Prices vary, but all those you mention are showy and cheap.

CORRECTION: In Mr. Baker's paper on Brambles and Blackberries the name of No. 12 on p. 84 should have been *R. vitifolius* Cham. et Schlecht., not *R. nigrobaccus*, Bailey, which is the name of No. 11, and was duplicated by a printer's error.

LARIX OCCIDENTALIS: *H. R.* We do not know from whom you could obtain seeds of this plant, but it is probable that some of the American nurserymen have them. A gentleman recently left England for the purpose of collecting seed if possible. This species is considered to have superior qualities to those of the common Larch.

LOAM FOR CYPRIPEDIUMS: *Mr. P.* You had better apply to a firm of horticultural sundriesmen.

MANURE FOR VEGETABLE GARDEN: *B. B.* It appears very probable that the soil of the garden has been over-manured with stable dung, and so has become excessively charged with humus matter, and got into a sour condition. It would be advisable to stop the dung for a few years or only to supply a small quantity. Give the soil an immediate dressing of basic slag, 7 lbs. to each pole of ground; this should be dug in so as to get well incorporated with the soil before sowing and planting begins in spring. This dressing may advantageously be followed in about a month's time by 5 lbs. of lime to each pole of ground. If you can get lime finely pulverised, but not slacked, it will be best, but if this cannot be procured, then use ordinary quicklime. This should be lightly forked or raked in. Slag is best to mix with the lower layers of soil, and lime with the surface, where it corrects the acidity and assists the micro-organisms in their work of nitrification. When too much dung has been used a process termed "denitrification" takes place, which prevents the nitrifying bacteria from working. The application of slag and lime corrects this evil, and sets the nitrate-forming organisms again at work. If you are planting Cabbages again this year use a little nitrate of soda as a top dressing around each plant when they are fully established, or a little finely sifted fowl manure would answer the purpose.

MUSHROOM SPAWN: *J. K.* There is very little sign of spawn in the sample you send, but whether it was there originally and has failed to grow we cannot tell.

NAMES OF FLOWERS, FRUITS AND PLANTS.—We are anxious to oblige correspondents as far as we consistently can, but they must bear in mind that it is no part of our duty to our subscribers to name either flowers or fruits. Such work entails considerable outlay, both of time and money, and cannot be allowed to disorganise the preparations for the weekly issue, or to encroach upon time required for the conduct of the paper. Correspondents should never send more than six plants or fruits at one time: they should be very careful to pack and label them properly, to give every information as to the county the fruits are grown in, and to send ripe, or nearly ripe, specimens which show the character of the variety. By neglecting these precautions correspondents add greatly to our labour, and run the risk of delay and incorrect determinations. *Correspondents not answered in one issue are requested to be so good as to consult the following numbers.* **FRUITS:** *T. Z.* Hanwell Sourcing—*George Brooks.* 1, Pile Russett; 2, Welford Park Non-such; 3, Lane's Prince Albert.

PLANTS: *W. O.* 1, *Cupressus Lawsoniana*; 2, *Sequoia sempervirens*, Red-wood; 3, *Juniperus virginiana*; 4, *Tsuga canadensis*, the Hemlock Spruce.—*S. S.* *Narcissus odoratus rugulosus*.—*B. H.* *Mesembryanthemum falciforme*.—*E. G. Richmond.* Both *Oncidium prætexum*.—*R. S. K.* The flowers were faded on arrival, but they are doubtless of *Zygopetalum crinitum*.—*J. P. R.* 1, *Codiaeum (Croton) pictum*; 3, *Codiaeum Weissmanni*. Apple next week.—*C. B.* *Epidendrum ciliare*.—*A. D.* 1, *Cypripedium Mons. de Curte* (Boxallii × insigne Chantinii); 2, *C. Astrea* (philippinense × Spicerianum).—*W. D.* 1, *Pteris longifolia*; 2, *P. cretica cristata*; 3, *P. tremula*; 4, *P. serrulata*; 5, *Nephrodium molle*; 6, *Davallia Mariesii*; 7, *Pteris umbrosa*.

NUTS: *W. H. R., Worksop.* The Brazil nut-like specimens are *Sapucaia* nuts, the produce of a tall, tropical South American tree, *Lecythis ollaria*. The small nut is a species of *Carya* or *Hickory* allied to the Walnut.

PEACH TREES CASTING THEIR FLOWER-BUDS: *R. H. C.* Your five-year-old, strong-growing Peach trees received a check during the summer or autumn of last year, and this has taken effect as soon as you commenced to force them. Probably the borders in which the trees are growing have been allowed to become dry (instead of being kept uniformly moist all the year through), and the foliage may have been left to become a prey to red-spider after the crop of fruit was taken. The watering of the borders should receive continued attention after the crops have been taken and up to the time the trees shed their leaves; the trees being syringed thoroughly overhead on the morning and afternoon of bright days until the foliage begins naturally to change colour. We have never known trees of the variety you mention that were planted in properly-prepared borders and subsequently properly attended to in the details we have pointed out cast their fruit-buds. You say you have kept the borders well watered, but have you ever examined them a day or two after watering to ascertain the real condition of the soil 18 or 20 inches from the surface? If you have not you are, so to speak, working in the dark. It is essential to apply sufficient water to thoroughly moisten the whole of the soil forming the border.

ROSE STEMS BORED BY GRUBS: *G. W. L.* The Rose shoots contain little colonies of the larvæ and pupæ of a small wild bee, and possibly those of the common British species, *Pemphredon lugubris*. The habits of the parent insect is to burrow into decaying wood and in Bramble stems, &c., where she forms little chambers or cells; in each of these she lays a single egg, and provisions it with plant-lice as food for the future grub. The Aphides are collected together into a ball and carried to the nest; and when a sufficient number has been collected the cell is closed and another is formed until the habitat is completely filled. If you examine the dark and rather loose material which forms a thick, wad-like barrier between some of the cells you will find that it is composed entirely of the remains of plant-lice, and here and there an almost perfect example may be detected. These insects are not known to be injurious, but may be considered as beneficial. If, however, you are desirous of preventing them making their nests in the Rose stems, you should cover the cut ends of the larger branches or stems with some form of grafting wax, taking care to push it well into the pith, as you will see that this is the point of entry.

SUCCULENTS: *R. P.* Apply to Messrs. H. Cannell & Sons, Swanley, Kent, or Mr. Franz de Laet, Contich, Belgium.

THE DOUGLAS FIR: *W. P. K.* We are not able to give a name to the varieties you send. Both appear to be like the Vancouver or Oregon forms, which for climatal reasons are best adapted to this country. From one bag of seed you may obtain many varieties. The tree has a very wide range from the moist temperate coast regions of north-western America, through the Rocky Mountains to Colorado, and even as far south as the arid regions of southern California and Mexico. It grows at the sea-level up to 10,000 feet in Colorado, and is at its best in Oregon and southern British Columbia. The species thus shows wonderful powers of adaptation. One closely allied if not identical species has lately been found in Japan. In buying seed you should, if possible, ascertain in which region it was collected. As an illustration of the extreme variability of this tree, it may be mentioned that Sargent found in Montana at a height of 6,000 feet, a plant of the Douglas Fir only 18 inches in height, but covered with cones of full average size.

VIOLETS DISEASED: *W. B.* The plants are affected with a fungoid disease. Burn the diseased plants and start afresh, selecting a fresh site for the bed and healthy stock procured from a distance.

COMMUNICATIONS RECEIVED.—*E. B.* (Apples next week: the shilling has been placed in the R.G.O.F. box.)—*F. J. G.* (next week; thanks for 2s. for R.G.O.F. box.)—*C. W.* (we quite understood)—*G. P.*—*J. R.*—*A. Voss*, Berlin—*C. W. T.*—*J. R. B.*—*D. T.*—*J. G. P.*—*A. F.*—*F. L.*—*F. P. G.*—*D. H.*—*C. E. S.*—*J. B.*—*W. D.*—*H. J. C.*—*H. R.*—*S. C.*—*T. W. B.*—*R. P. B.*—*H. W.*—*W. H. JAMAICA AND ITS FUTURE.

THE terrible calamity that has befallen Jamaica will tend to draw increased attention to the agricultural capabilities of that island. Though the information that has come through at the time of writing regarding the safety or otherwise of civilian staffs is very meagre, incidental statements in the daily Press would indicate that most of the officers are safe. An extract from a letter in the *Daily Telegraph* from the *New York Times* says that the leading members of the West Indian Commission, headed by Sir A. Swettenham and Sir Daniel Morris, "opened an Imperial Conference, at which the whole trade of the island would have been reviewed, including the sugar, rum, banana, coffee, and cocoa outputs, and a new starch made from Cassava, from which great results are expected. But over and above all these was the idea of Sir Alfred Jones, as president of the Cotton Growers' Association, of re-establishing cotton-plantations in Jamaica, and thus providing the Lancashire market with an ever-increasing supply of sea island cotton." For the moment these expectations would

appear to be deferred; but it is not safe to hazard any conjectures until more details are received. In the meantime, however, we may refer to some facts bearing on the prospects of the successful cultivation of such economic plants as those mentioned above, and which are recorded in the most recent official reports, copies of which reached the writer from Jamaica only a few days before the earthquake.

With regard to the sugar-cane, it is stated that 8 acres and 23 perches were devoted to experimental culture. Some of the varieties had been condemned and destroyed, and the land, after being prepared, was planted with other varieties and selected seedlings. The Demerara seedlings have been propagated and planted to the fullest extent. The method of sending out cane tops in perforated barrels was abandoned, and they were distributed in bags with success, and an appreciable saving was effected in the cost of packages and of freight, so that a much larger number was distributed than was thought possible at the beginning of the season, the total number of tops and cuttings sent out being 113,089.

The genuineness or purity of much of the so-called Jamaica rum sold in the United Kingdom has attracted some attention of late. In Jamaica it is reported to have occupied a prominent place in the investigations of the island-chemist, who has been busily engaged studying the micro-organisms present in distillery materials, and the conditions for the economic production of the flavouring materials upon which the quality of Jamaica rum depends. A means of increasing the flavouring power of rum by utilising waste materials has been devised, and at the request of the two Planters' Associations is being patented in the chief rum-producing countries. All rights in the patents have been assigned to the Government for the benefit of the sugar-experiment station. The commercial results of the enterprise have still to be ascertained, but it has been shown that the process is practicable, and can be operated without expert assistance. The results obtained in the experimental distillery indicate that many estates are losing at least 25 per cent. of their produce, and it is clear that great economies could be effected by a more adequate understanding of the conditions affecting the yield and quality of rum as made in Jamaica. The work of the fermentation-chemist is rapidly bringing the problems of flavour production within closer knowledge, and the further prosecution of this investigation should prove of great service to the industry. One result of these researches is stated to have raised the value of the rum from 3s. 6d. to 7s. 6d. per gallon.

In the matter of coffee, planters in Jamaica have been advised to extend the area of its cultivation in consequence of its increased consumption and decreasing production. The report says: "Coffee planted now cannot come in for four or five years, but by that time the increased consumption which has been promoted by the long prevalence of low prices, added to the possible, if not probable, diminution of supplies from South America, may combine to make the crop once more a very profitable one. At any rate it is not likely to be under greater disadvantage than

at present, and it is not subject to great loss by hurricanes." As an illustration of the increasing trade in coffee with Jamaica, the total exports in 1904-5, ending March 31, amounted to 50,724 cwts., against 83,920 cwts. in 1905-6, 9,749 cwts. reaching the United Kingdom in the former year and 12,085 cwts. in the latter. And again with cocoa, the total exports in the former year were 22,237 cwts., and in the latter 32,587 cwts., the quantity sent to the United Kingdom last year being rather more than double that of the preceding year.

With regard to Cassava starch, "it has been shown that the plant can be grown without irrigation in the plain of Liguanea, in Jamaica, to give a yield of starch greater than has ever been recorded of any starch-producing plant. It gives this large yield upon a soil and with a rainfall that would not give good crops of sugar cane without irrigation; and large areas of land at present producing little or nothing could be profitably used for the growth of Cassava for starch-manufacture. Already 16,641 cuttings have been distributed to growers in various parts of the island, and the demand has been so great that a few stock-plots have been established to supply cuttings only.

Jamaica cigars have already appeared more than once at the exhibitions of Colonial produce at the Royal Horticultural Society and at the Crystal Palace, and have been reported as of excellent, though not always of uniform quality. It has been, however, stated "that with larger stocks of tobacco which will be formed as the trade increases, and when a larger acreage has been put under cultivation, the quality will gradually become uniform."

It is sad to be obliged to think that these improved prospects in the future of Jamaica which were officially put forth only a few weeks back are likely at any moment to be officially reversed. *John R. Jackson, Claremont, Lymington, Devon.*

NEW OR NOTEWORTHY PLANTS.

PLAGIOSPERMUM SINENSE.*

THIS is a shrub from North China belonging to the family Celastraceæ, or, as seems more probable, to the Rosaceæ. It was originally described by Oliver, as cited in the footnote, but it has not as yet made its appearance in garden-catalogues so far as we can tell. Our specimen was kindly forwarded by Mr. Smith, of Newry, whose nurseries are remarkable as the home of many new and interesting plants. The shrub has slender, spiny branches, covered with a smooth, greyish bark, which reminds one of that of *Lycium sinense* in general appearance, though, of course, the plant is widely different in floral characteristics, being more like those of a *Cotoneaster*, except in the ovary. Leaves tufted, glabrous, linear, lanceolate or oblanceolate, tapering to a short stalk, and surrounding a short, straight axillary spine. Each leaf is about 1 inch long, $\frac{1}{2}$ inch broad (3 cm. by 6 to 7 mm.). Stipules small, deciduous, brown, covered with reddish hairs. The flowers are about 12 millimetres wide, with a vase-shaped calyx, with five lobes and five yellow petals springing from the

**PLAGIOSPERMUM SINENSE*, Oliver, in *Hooker Icon. Plant.*, vol. vi. (1896), tab. 1526. Forbes and Hemsley Enumeration, *Journ. Linn. Soc.*, xxxvi. (1906), p. 502.

throat. The stamens are 10, the ovary solitary oblique, at the bottom of the flower-tube, with a short style and two ovules. The principal difference between the specimen submitted to us and that described by Oliver is that in our specimen the flowers are all but sessile, whilst in Oliver's description, as in his figure, the flowers are raised on pedicels, 10 to 15 millimetres long. We have not seen the fruit. From its habitat in North China and near Mukden, it may be considered hardy in this country, and flowering at this season it is welcome. *M. T. M.*

ORCHID NOTES AND GLEANINGS.

CYPRIPEDIUM MORGANIÆ X.

In our issue for August 21, 1886, we reproduced a full-page illustration of this hybrid *Cypripedium*, the result of *C. superbiens* x *C. Stonei*. Fig. 29 shows a plant that was exhibited at a recent meeting of the Scottish Horticultural Association by Mr. George Wood, gardener to James Buchanan, Esq., Oswald House, Oswald Road, Edinburgh, a photograph of which was sent us by Mr. A. D. Richardson. The broad petals, which much resemble those of *C. Stonei* platytaenium, are white, slightly tinged with sulphur colour, and profusely blotched with purplish brown. The dorsal sepal is white, tinged with red, and the lip white, tinged and veined with rose colour. The foliage is broad and very slightly tessellate.

CYPRIPEDIUM MRS. SUTTON WILLOUGHBY (CHARLESWORTHII X CHAMBERLAINIANUM).

An inflorescence and a leaf of a very delicately-tinted hybrid of the above parentage is sent by Sir Charles W. Strickland, Bart., Hildenley, Malton, Yorks. (gr. Mr. W. Smith). The leaf is broad and dark green; the flower stalk purple and downy, and giving evidence of producing several flowers in succession. The ovary is sheathed by a broad, green, purple-spotted bract. The flower has the dorsal sepal circular in form, reddish rose on the lower two-thirds, and white with a slight green tint showing from the back, on the upper third. The horizontally-extended petals are tinged and veined with purple; and the lip light rose with a yellow upper margin. The staminode is light purple with a yellow-raised centre. The lower sepals are pale green.

LYCASTE SKINNERI.

From the Royal Botanic Gardens, Glasnevin, Dublin, Mr. F. W. Moore, the Curator, sends a three-flowered inflorescence of a large and remarkably fine form of *Lycaste Skinneri*, all the blooms being well developed and fully open, the upper part having the appearance of a raceme with the flowers all facing the same way. Mr. Moore remarks of the plant: "This particular variety always has twin-flowers, and each year one or two of the stalks has three." The character seems to be fixed in this variety, and on removing the bract at the base of the third flower a rudimentary bud is revealed, showing that a fourth flower is possible. It is a pretty, light-coloured variety, with remarkably broad sepals and petals. *J. O'B.*

VEGETABLES.

WINTER AND SPRING CARROTS.

MANY persons prefer a small or medium-sized Carrot at all seasons of the year, and there is no reason why young, fresh roots should not be obtainable at all times. Of late years I have found it a much better plan to sow half a dozen times from February to August, instead of one or two large sowings in the early spring. Of course, I am only writing from a private grower's view, and I know that a market grower must have size in his roots, also that young Carrots soon shrivel, and when long out of the ground do not keep in a pre-

sentable condition, but in the case of a private garden I strongly advise their being sown at intervals, harvesting them when still young. Some persons may object to this mode of culture, and may think that more seed is required, but such is not the case, as frequently the seeds are sown too thickly, and much labour is entailed in thinning the seedlings and in keeping the rows clean. There may also be the objection that in some exposed gardens the young roots would not winter in their growing quarters, but in this I have found no difficulty; indeed, the Carrot is quite hardy. I admit the tops suffer a little in severe weather, but not so the roots, and it is an easy matter to lift some and to store

heavy clay soil this mode of culture may be found somewhat difficult of success, but the difficulty may be overcome by preparing a small piece of land, and dressing it liberally with such materials as wood ashes, road scrapings from limestone roads, old mortar rubble, or old potting soil of any kind. I should add, that for winter supply it is well to change the quarter, if possible, each season. It is also necessary to dress the land thoroughly before sowing the winter supply with soot and lime to destroy insect pests which attack these plants. Soot and lime used freely will also furnish the plants with food, and be better for this purpose than fresh animal manures. In poor land I

FIG. 29.—A WELL-GROWN PLANT OF CYPRIPEDIUM MORGANIÆ X.

them in sand, or, better, to cover some with litter or Bracken for use during severe weather. The best kinds for early sowing are Early Nantes and Early Scarlet Horn. For May and June such kinds as Sutton's Early Gem or Veitch's Scarlet Model. These two last-named are excellent varieties, and are equally good for later sowings, but for the latest supply, that is from January to May, I prefer the smaller roots advised for the earliest or February sowing, as these stand the winter well, and their roots are quite large enough for most purposes. For the earliest crop, warm sheltered borders are advisable, but for the other sowings an open quarter is the most suitable position, as it is best to grow the plants as hardy as is possible. In

have used Guano, when preparing the soil, with good results. In some gardens there is a difficulty in producing Carrots free from disease, and in such cases I advise a trial on the plan described above. *G. Wythes.*

FRUIT REGISTER.

LATE PEARS.

WITH regard to Mr. Markham's remarks on p. 37 on late dessert Pears, I may say that with me Bergamotte d'Esperen is a first-rate late Pear, and by growing it on walls of different aspects, and occasionally placing a few fruits according to the demand in a higher temperature than that of the fruit room, ripe fruits may be had from January until April. The flavour is very good.

Forelle is an excellent variety, and, ripening at about Christmas time, its handsome appearance adds to its value. I find it succeeds best on a west wall, and if the roots are afforded plenty of water and stimulants during the growing season, the fruit attains a good size, otherwise it is rather small.

facing to the south, the fruits will not always ripen sufficiently for dessert. There are some double-grafted trees of this variety growing in these gardens, which produce large, sweet fruits of agreeable flavour. I shall not discontinue growing it yet. Among the varieties Mr. Markham says he is planting this season is *Lé Lectier*. I planted this variety here five years ago, and it has succeeded very well. It is a vigorous grower, a good bearer, producing fruits of large size, has melting flesh, and is rich in flavour.

During the last six years I have planted a good many Pear trees against walls in these gardens, which, with few exceptions, have done very well. It is in reference to these exceptions that I wish to make enquiry. They are horizontally-trained, and growing on the Pear stock. Up to the middle of June last year, they grew

depth, 4 feet in width, and 6 feet long, and plenty of drainage provided. I am quite sure there is no stagnant moisture in the soil. Will some of our fruit-growers please give their opinion on the matter? &c.

Mr. Markham says it would be interesting if growers would record their experience as to the best varieties of Pears for keeping up a good supply during the first three months in the year. When one considers that the quality of Pears is greatly influenced by soils and sites, it makes the task of giving a selection more difficult. However, so far as these gardens are concerned, I plump for the following:—*Lé Lectier*, *Nouvelle Fulvie*, *Olivier de Serres*, *Josephine de Malines*, and *Duchesse de Bordeaux*. *W. J. Snell, Gardener to Lord Clifden, Wimpole Hall, Royston.*

FIG. 30.—A BORDER OF "SUCCULENTS" IN THE PUBLIC PARK AT GREENWICH.

(See also illustration in last week's issue.)

My experience with *Beurré Rance* as a dessert Pear is similar to Mr. Markham's, but I find the fruits useful for kitchen purposes. *J. Murray, Sopley.*

MR. H. MARKHAM (see p. 37) speaks highly of the variety *Nouvelle Fulvie*. I can endorse all he says of this grand variety, having grown it here for six years. The tree is hardy and grows well, is a good bearer, and the fruits are of large size, juicy, and possess rich flavour. *Passe Crasanne* growing against a south wall here is not satisfactory. I consider it is a very poor doer, as, in spite of mulching, watering, and feeding, it makes only a small amount of growth. It bears well, and the fruits are of splendid quality and flavour. My experience with *Beurré Rance* is that unless it is grown on a wall

as well as could be desired, and then, without any apparent reason, the leaves became pale and thin (showing, I believe, an absence of chlorophyll), and the points of the shoots—more especially the extension shoots—gradually turned brown and died back to within a few eyes of the point at which they were pruned in the previous year. Knowing, as I do, the conditions under which they were planted, it is difficult for me to assign any reason for the trees behaving in this way. Perhaps I ought to explain that they were planted in equal parts of turfy loam, and the top spit from the kitchen garden, the latter being rich in humus, to which were added some burnt earth and old mortar rubble. There are plenty of surface roots. Holes were made to the extent of 3 feet in

EARLY RIVERS CHERRY.

THIS variety is a valuable addition to dessert Cherries, and is also an excellent variety for market purposes, as its fruits ripen early, thus ensuring good prices. The tree is of robust growth, and is a prolific and constant bearer, scarcely ever missing a season without cropping. It is suitable for pot culture, and for training against walls. The growths have a somewhat pendulous habit, and for that reason standard trees should be pruned hard back for several seasons. The fruits are of a deep black colour, large, very juicy and of excellent flavour. They ripen out of doors during July, and very early in June under glass. They are capable of hanging for a considerable time when ripe. *T. W. Birkinshaw.*

BLUE HYDRANGEAS.

Has the real cause of some Hydrangeas producing blue flowers ever been satisfactorily cleared up? Various theories have been propounded, the iron filings of our German friends (quoted in vol. XL on p. 443) among them. That they may have been able to produce blue flowers by growing the plants in soil impregnated with iron and watered with alum water is quite possible. But does this treatment always succeed, and do Hydrangeas produce blue flowers without iron? To this latter query I say most decidedly yes. I enclose herewith a photograph of a Hydrangea growing in front of a cottage in central Essex. The photograph was taken in August, 1905, and the plant was a mass of bloom. But here was a riddle: the plant bore both blue and pink flowers, intermixed all over the bush in all stages of development. I closely questioned the tenant of the cottage, and found that this was the usual habit of the plant. But now comes riddle No. 2. In the adjoining garden is a smaller plant, an offset from plant No. 1; it was in full bloom, and showed the extra vigour of a younger plant. The trusses of bloom, too, were much finer, but they were all pink. Now what have we at work here, and where does the iron tonic come in? How is it that one truss of bloom gets it and another does not, and why has plant No. 2 reverted entirely to the pink habit when only a few feet divide the two plants? The original plant and I are old friends. I admired it in days gone by, long before the colour theory interested me? I traced its history for much more than over half a century, at the time that I took the photograph. The aspect is about south-west, and the plant seems to receive no attention whatever beyond an occasional cutting back to keep it within bounds, and the surrounding ground is simply a grass plot. I was completely puzzled at the time. All the theories hitherto advanced were wrong, as far as I could judge, for here was a plant that set them all at defiance. Perhaps some of your readers can solve the problem. *James Brown, Alexandra Park, Glasgow, N.B.*

[The photograph is unsuitable for reproduction. Is it known whether the colouring matter of this plant is solid or liquid?—Ed.]

NOVEMBER AND DECEMBER IN MY FLORIDA GARDEN.

(Continued from page 45.)

SHRUBS.

As a rule, the evergreen Japanese shrubs, if well cultivated and manured, thrive wonderfully well in our poor sandy soil. Some species, however, defied all my attention and care. *Damcanthus indicus*, *Aralia chinensis* (*A. japonica*), and others soon died; while *Photinia serrulata*, *Osmanthus aqifolium*, *Michelia compressa*, and most of the deciduous *Magnolias*—which, however, flower profusely in November and December—have a straggling, thin growth. *Ilex latifolia*, *Othra japonica*, and *Viburnum odoratissimum* grow moderately well; while *Gardenia florida*, *Michelia fuscata*, *Raphiolepis indica*, *Pittosporum tobira*, *Cleyera japonica*, *Ternstræmia japonica*, *Illicium anisatum*, *Cinnamomum camphora*, *Cinnamomum cassia*, *Aralia papyrifera*, *Hydrangea Hortensia*, and several of the evergreen Oaks belong to the most exquisite decorative evergreens of my garden. Among those in full bloom in November and December *Daphne indica* must be mentioned first. It is a shade-loving shrub of slow growth, but the perfume exhaled by the densely-packed flat flower corymbs is so strong, so delicious and aromatic that it should find a place in all collections where choice evergreen shrubs are desired.

CAMELIAS.

The queen among autumn-flowering Japanese evergreen shrubs is undoubtedly the *Camellia*, or the "*Japonica*," as it is called by most people in the south. It grows to perfec-

tion in Florida. Among the many garden forms of *Camellia japonica* in my collection, the first to flower is the common double white, which opens its first buds early in November. At Christmas many of the varieties are "in all their glory," and the sight of these noble and refined flowers against a background of *Magnolia grandiflora*, huge bushes of *Michelia fuscata* and Palms never fades from memory. At this time *Camellia sasanqua* is still more showy, and the bushes are a sheet of colour, which is never the case with the former. The foliage can scarcely be seen beneath the blossoms. The double forms are as floriferous as the single ones, and they are just as beautiful as the best varieties of *C. japonica*, though much smaller. The single rose-coloured form reminds one strongly of some of our wild Roses. The foliage of this species is small, deep green, and very glossy. The flowers have been described as fragrant, but I find the odour somewhat musty.

ELÆAGNUS.

The different species of silver shrubs or Oleasters are veritable jewels among Japanese evergreens, particularly *Elæagnus reflexa*, which, by means of blunt, spine-like, hooked or reflexed branches, scrambles high into the Oaks, forming grand masses of tangled green. It is a pleasure to walk underneath this canopy of dense, dark green foliage, particularly when the whole mass is in flower, or when the berries are ripe. In October and November the small, inconspicuous, greyish-white flowers appear in incredible numbers, filling the air with a most delicious and peculiar clove-like perfume. The plants swarm with insects during their blooming time. This is the most rampant grower of all the species, and it attains a height of about 30 feet. The annual greyish-brown shoots are in the first year devoid of foliage, but they are provided with reflexed hooks. They are sometimes 20 to 25 feet in length, and they climb in all directions. *Elæagnus Simoni* is of still denser growth, but it is not such a strong grower as the last named, although the foliage is larger and more glossy. It forms masses of tangled growth of a rounded form, 15 feet in height, and from 10 to 20 feet in diameter. It blooms most abundantly in November, the fragrance of the flowers being quite strong and similar to that of the former species. The elongated, orange-red berries are covered with brown dots, and they are produced in such abundance that all the branches are densely covered with them. They are very juicy, and can be used for the same purposes as currants. The first fruits ripen early in January, and the fruiting season is prolonged until the middle of March. This species is also provided with blunt hooks, which enable the shoots to form a dense mass of inextricable growth. The most valuable and beautiful of all the silver shrubs is *Elæagnus macrophylla*. The foliage is large, of a deep glossy green shade, and, as in the other species, with a beautiful silvery-white under surface. The growth is delicate, but very dense, and wherever seen, a well-grown specimen of this noble species has a very elegant appearance. It finally assumes large proportions, fully-developed bushes being 6 to 10 feet in height, and as much in diameter. It flowers profusely at this season, and pervades the air with a delicate Carnation-like odour. One flower is scarcely noticeable, but masses of them produce a delicious fragrance. The colour of the small flowers is dull white, and the fruit is shaded a light greyish white. Variegated forms of this plant are very pretty and grow equally as well as the green-leaved kinds, but they are dwarfer in habit and need a little more attention. *E. pungens* *Frederici variegata*, *E. pungens maculata*, and *E. Simonii tricolor* are all very beautiful subjects, partly provided with golden-yellow and partly with white variegated foliage. All the Oleasters simply revel in the driest, sandy soil, and in the fullest sunshine. They will not thrive in moist spots or on heavy ground. On account of their density they form favourite nesting sites for Cardinal Red birds, mocking birds, ground doves, and brown thrashers.

Another very sweet-scented Japanese shrub now in full bloom is the Sweet Olive (*Osmanthus fragrans*), a very deliciously perfumed plant, but a very poor and straggling grower, and one that will not succeed on high lime land. A specimen planted with several *Michelia fuscata* about 10 years ago has only grown about a foot high, while the

Michelias have reached a height of more than 8 or 10 feet.

Cycads are expensive plants, and for this reason I have not been able to plant them on a large scale, except *Cycas revoluta* and our native *Zamia floridana* and *Z. pumila*. The first named is now in fruit, the large seeds being covered with a bright orange-scarlet coloured material. These plants grow freely, and form glorious companions to our Palms, *Magnolias* and other evergreens. Our native *Zamias* are very showy objects when in fruit, large clumps producing numerous deep-brownish cones, which show their bright coral-red seeds to much advantage. *Zamia mexicana* grow finely here, and *Z. furfuracea* rivals it only in elegance, but not in size. *Cycas siamensis* and *C. circinalis* make a very rapid growth, and are always objects of grace and elegance. I protect the crowns of these four last-named Cycads by bunches of Spanish Moss, or by banking them with dry sand. In very cold weather they lose their foliage, but they always renew it in the following season. *Dioon edule* is as hardy as the common Cycas. I have a fine large specimen about 60 years old, with a magnificent crown of foliage.

Speaking of ornamental fruits, the glowing red berries of the Holly (*Ilex opaca*), of the Dahoon (*I. cassine*), and the coral *Smilax* (*Smilax Walteri*), all natives, add beauty and variety to our gardens. Another *Smilax* (*S. beyrichii*), with very fragrant flowers, is in spring covered with its blue-black berries. In the woods this forms a fine climber, but in gardens it spreads very much, and its disposition to climb over the choicest trees and shrubs is scarcely controllable. The immense clusters of black berries, each the size of a small pea, hanging from among the leaf-crowns of the Palmettos (*Sabal palmetto*, *S. blackburniana*, and *S. mauritiformis*) are very prominent. The native Wild Olive (*Osmanthus americanus*), a fine, broad-leaved evergreen ornamental tree of low dense growth, provided with branches from the ground up, is adorned with numerous bluish-black fruits, the size and shape of an Olive. The Wax Myrtle (*Myrica cerifera*) is also in fruit. The bluish-white berries growing densely along the branches are thickly covered with a powdery, wax-like substance, which was formerly extensively used in the manufacture of candles. The large rounded bushes, never more than about 15 feet high and often 7 feet in diameter, are of a dense habit, and the abundant, small, deep-green foliage has a decided brownish cast. This species is one of our finest ornamental evergreens, and the foliage has the additional charm of possessing a fine aroma. These Wax Myrtles are swarming with Myrtle Warblers (*Dendroica coronata*) and kindred species—northern migrants and winter sojourners—which are extremely fond of the berries. Of the exotic tropical shrubs, only the Golden Dewdrop (*Duranta Plumieri*), a half-climbing, thorny plant, is in fruit, the abundant golden-yellow berries being very ornamental.

PALMS.

Palms in the open air are always a revelation to me. There is nothing more enchanting, more imposing, more noble than well-developed specimens of Palms in our Florida gardens. They are the veritable "princes of the vegetable kingdom," but they are capricious in their requirements, and need a good deal of attention, and their development, even under the most favourable conditions, is extremely slow. Only a very limited number thrive here, and our gardens are, in regard to variety, much poorer than those of California or the Riviera. This deficiency in species is mostly due to our poor sandy soil, and to our occasional cold weather. *Washingtonia filifera*, the California Fan Palm, grows well in the flat woods, where the clay is near to the surface. The beautiful *Erythra armata* and *E. edulis*, both from California, dislike the humidity of our atmosphere, as well as the sandy soil. All the Australian species are a failure, for they are not able to stand our mid-summer's sun or our winter's cold. *Jubæa spectabilis*, from Chili, remains healthy for many years, but it scarcely makes any progress in its growth. *Livistona sinensis* and *L. australis* grow well in rich, moist soil in shady positions. All the Palms that thrive here are at their best late in the fall of the year, after they have finished their annual growth, forming in com-

pany with Bamboos a magnificent sight wherever they have been planted. *Trachycarpus excelsus*, *Chamærops humilis*, and *Acrocomia Totai* grow freely in rich soil. My specimens, about a dozen years old, are very fine. Among all the Palms, however, the different species of *Cocos* are the most elegant, graceful and conspicuous; while such species as *Cocos australis*, *C. Datil*, *C. eriospatha*, *C. Romanzoffiana*, and an unnamed species from Entre Rios, in Argentina—the stateliest and most massive of all—ripen their fruit in midsummer. Other species, like *C. Blumenavia*, *C. Gærtneri*, *C. Bonneti*, *C. Yatai*, &c., are constantly bursting their massive club-like flower spathes, and ripen their strangely aromatic fruit continually. Spores of Ferns have found their way to the spaces between the old leaf-stalks and the trunk, with the result that beautiful clumps of *Polypodium aureum* and *P. incanum* are decorating these Palm-trunks in a most charming manner. Some fine specimens of *Cereus grandiflora*, *C. nycticalus*, *C. Martini*, *C. Bonplandii*, and *C. triangularis* clamber up into the crowns, whilst masses of *Phyllocactus crenatus* are quite a feature along the massive trunks. The fruit, which varies in size from that of a Pea or a Grape to that of a Plum, reminds one in its fragrance of the Pineapple. It is greatly relished by children, and the chickens fly up in the crowns and eagerly feed on it. Quite as successful and much more massive in growth are such Date Palms as *Phoenix canariensis*, *P. sylvestris*, and a hybrid between the two. In rich soil these plants reach an enormous size in the course of a dozen years, and form trunks as thick as water-barrels. They bloom in November and December. The common Date (*P. dactylifera*) also flowers at this time of the year, but it is far inferior to the three above named, its foliage being scant and stiff, and its growth disappointingly slow. *P. rupicola* and *P. reclinata* form slender trunks, with glorious crowns of foliage, while *P. spinosa* and *P. senegalensis* form dense, many-stemmed thickets of great beauty. This latter class of Date Palms is in fruit just now. The bunches of fruits, which are rather small and smooth, are quite showy, being displayed on bright yellow, panicked stems. The fruit itself is of a dull brownish colour. All the Sabals do well here, and all are now in full fruit. *Sabal mauritiformis* from Jamaica and Trinidad is the most imposing species, but the bluish-green *S. Blackburniana* from Bermuda, *S. mexicana* from Mexico, and our indigenous *S. Palmetto* are scarcely less majestic. Large groups of the latter form glorious pictures in many gardens, and they are still more glorious along the St. Johns, the Ocklawaha, the Tomoka, and other Florida rivers, where they form ideal sceneries of wild-wood, plant life. The dwarf *Palmetto* (*Serenoa serrulata*) grows in big clumps everywhere in the woods. It flowers in spring and ripens its juicy, unpleasantly-sweet, yellowish-brown fruits late in the fall. *Rhapidophyllum hystrix*, the Blue *Palmetto*, at present in flower, is one of our most beautiful native dwarf Palms.

From the flower-embowered verandah we see the silvery water of Lake Audubon gleam through vistas of Magnolias, Palmettos, Bamboos, Wax Myrtles, and Laurel-Cherries (*Prunus carolinensis*). Around the lake the soil consists of alluvium and rich vegetable mould, exhibiting the most exuberant fertility after it has been thoroughly worked for several years, or until its sourness has been neutralised. In this moist black soil, *Crinums* grow to a gigantic size, and Cannas can only be grown successfully here, though the common *Canna caterpillar*, evidently confined to Florida, does much harm. This is the right kind of soil for the *Scitaminaceæ*, while the different species of *Curcuma*, *Kämpferia*, *Maranta*, *Musa*, *Strelitzia*, *Heliconia Bihai*, *Ellettaria Cardamomum*, and many others may be arranged in strikingly beautiful beds. *Alpinia nutans* assumes in this rich soil gigantic proportions, growing 10 feet high, and consisting of hundreds of shoots, which furnish gorgeous flower-spikes the following year. The flowers are very fragrant, very characteristic, very elegant, and brilliantly-coloured, being orange, yellow, and white. The foliage also is very fine and strongly aromatic. This is one of the most precious tropical ornaments of our gardens. It blooms most profusely in October and November. Its congener, *Alpinia mutica*, commonly known here as the Ginger

plant, has very showy white flowers, with a large, bright yellow lip, veined with crimson.

The Butterfly Lily (*Hedychium coronarium*), with intensely fragrant, pure white flowers, and the Garland Flower (*H. Gardnerianum*), with large spikes of yellow and red blossoms, and the sulphur-yellow *H. flavum* attain a very large size in this moist spot. They grow from 4 to 8 feet high, and form large clumps in a single season. They are late bloomers, and are at their best by the beginning of November. The showy *Musa coccinea*, never growing taller than 5 or 6 feet, forms a very fine companion plant to the above-named species. It is scarcely ever out of flower, and is always conspicuous. The larger-growing Bananas, particularly the Cavendish, Hart's Choice, and the Orinoco, grow most vigorously near the lake, and produce ripe fruit in abundance if the stalks have not been cut down by frost during the preceding winter. *H. Nehrling*, Florida.

(To be continued.)

NOTICES OF BOOKS.

FLORE DE FRANCE.

THE last part, completing the third volume of this work, has been issued. It has occupied six years in preparation, and is the work of a provincial abbé in a rather remote district of France. The Abbé Coste has endeavoured to produce a book which shall be as serviceable as the well-known *Flora* of Grenier and Godron (1856), now superseded. A description and figure of the species to the number of 4,854 are given, with indications of localities and general distribution. As many of the species are common in western Europe generally, and many Mediterranean and Alpine species are in cultivation, this book will be an acceptable addition to the library of the plant-lover. It will remind the reader of the illustrated edition of *Bentham's Handbook*, but is, of course, on a larger scale. It has a full index. The publisher is M. Klincksieck, 8, Rue Corneille, Paris.

RAMBLES ON THE RIVIERA.

WE are frequently asked to recommend a book which, without being too technical, is sufficiently accurate to enable visitors to the lovely shores of the Mediterranean to name the plants they are likely to meet with, and to make them acquainted with the many points of interest they present. Just such a book is Dr. Strasburger's *Rambles on the Riviera*.* The eminent Professor of Bonn has made numerous visits to Liguria, and has explored the country from the Gulf of Genoa to Cannes and Nice. He is charmed with all he sees, and his enthusiasm will infect the reader. A better companion than Prof. Strasburger cannot be found. He enjoys everything, and while there is not much that he does not know, he never obtrudes his knowledge. No one, reading this delightful book, would imagine that it was written by one of the foremost investigators into certain very abstruse departments of botany of extreme importance, but hardly to be comprehended by the profane. He chats pleasantly about any or everything that turns up in his rambles, and proves himself a charming companion. An account is given of Sir Thomas Hanbury's garden at La Mortola—and the volume is dedicated to that generous protector of the sciences. The book is well printed on art paper, and is copiously illustrated with coloured illustrations of the most noteworthy plants. These illustrations are from drawings by Miss Louise Reusch, and are very faithful, but they are scattered through the volume, so that they are often placed, of necessity, away from the text that relates to them. Moreover, they are let in to the type, so that there is much and sometimes troublesome "overrunning." These flaws, if flaws they be, do not materially detract from the value of the work, particularly as on p. xix. is an alphabetical list of all plants figured with references to the pages on which they occur. The changes that have taken place of late years on the Riviera have not all been for the better, and the advent of motor-cars has detracted sadly from the pleasure of the visitor, and even endangers his life. Yet, even on the French Riviera, there are plenty of places where, "without let or hindrance, one may devote one-

self with earnestness to the ennobling study of nature." Many parts of the Riviera are now devoted to the culture of bulbs, Anemones, Roses and other flowers destined for the markets of the great cities of Europe, so that they form one vast flower-garden. Oranges, Lemons, and Olives abound—not the stunted Olive bushes one sees in Provence, but gnarled monarchs vying in picturesque effect with our Oaks.

The Palms and Agaves which form such adjuncts to the scenery are not of native origin, but have been introduced. Let those who say we should rely exclusively on native productions make a visit to the extreme eastern Riviera, where few introductions have been made, and they will acknowledge how greatly the picturesque effect has been enhanced by the noble Palms, Agaves and other plants which have been introduced by plant-lovers into the Western Riviera. The book has an excellent table of contents, and a copious index, so that we end as we began by heartily commending it to the visitors to this lovely coast.

The Week's Work.

FRUITS UNDER GLASS.

By ALEXANDER KIRK, Gardener to J. THOMPSON PATON, Esq., Norwood, Alloa, Clackmannanshire.

Pines.—The plants that were selected last month for fruiting early will now require a steady bottom heat of 80° to 85°, and the atmospheric temperature of the pit should be kept at about 65° to 75°, rising with sun-heat to 80°. Damp the paths once or twice daily, and admit a little air when the weather is favourable. Examine the pots in the plunged material, and see that the bed is not too hot, as freshly made-up beds with leaves, moss litter, or tan-bark often produce a violent heat, which is dangerous, although a little excitement at the roots at this stage is advisable. Succession plants should be kept in an atmospheric temperature of 60°, and a steady bottom-heat of 65° will be sufficient. Be careful not to over-water the plants, but keep them on the dry side until they are wanted for forming a succession supply. All the young, strong suckers which can now be obtained from plants which have fruited during autumn and winter should be carefully detached from the old stools. Pot them in turfy-loam, using 6-inch pots. Plunge the pots in a bottom-heat of 70°, where they will soon make roots, and should be useful next winter.

Melons.—Seeds should now be sown if ripe fruits will be required in May. Sow the seeds in thumb-pots filled with loam and leaf mould to within 1 inch of the top; place two or three seeds in each pot, and cover the seeds with similar soil. Plunge the pots in a bottom-heat of 75° in a pit. Apply a little tepid water to each, and place panes of glass over them. In a few days the young Melon plants will appear above the surface of the soil, and it will be necessary to remove all but one plant in each pot. As soon as the rough leaves have developed and the plants are sufficiently large to pot on, shift them into 5-inch pots, using turfy-loam and leaf mould, which have been well mixed together and warmed through by keeping in the pit for a few days. Plunge them again, when potted, in the same degree of bottom-heat. Immediately new roots have been made, apply a stake to each plant, and remove the plants to a shelf near to the glass in an atmospheric temperature of 65° at night, and 75° during the day. Admit air daily when the weather is fine, and spray the plants over with tepid water, keeping the house moist by damping the paths daily with water.

THE KITCHEN GARDEN.

By WILLIAM HONESS, Gardener to C. COMBE, Esq., Cobham Park, Surrey.

Early Pear raised from seeds that were sown in November on warm borders in front of vineries, or in other favourable positions, will have made by this time sufficient growth to require a little soil drawing up to them. Short sticks also should be applied to such varieties as Early Giant, which has so far withstood the winter well in these gardens, and is making fair progress. Dwarfier varieties, such as Sutton's Seedling, Green Gem, and Little Marvel, will not require stakes, but if some Yew or Spruce branches, 2 feet high, are placed at a

* Translated from the German by O. and R. Comerford Casey. Coloured plates, p. 444. London: T. Fisher Unwin.

distance of about 15 inches from the rows, on the east or most exposed side, they will be found to afford appreciable shelter from both wind and frost, at the same time permitting all the light and sun to reach the plants. As soon as the ground becomes sufficiently dry, and is found to be in good working order (but on no account whilst the ground is wet and sticky), another sowing of Early Giant and Duchess of York, &c., should be made in a good situation, and if a sowing of Duke of Albany or Superlative be made in 48-size (5-inch) pots, and these are placed in a cold house, such as a late vinery or Peach house, the Pea plants will be in good condition for planting out in trenches towards the end of March. If after planting out they are given a little protection from winds, they will well repay the extra labour bestowed.

Onions.—The sowing of Onion seeds in heat early in the year is becoming the general rule throughout the country, not only as was previously the case for the culture of bulbs for exhibition purposes, but also for bulbs for home consumption. Much finer bulbs can be thus grown, and the crops are cleaner, for it is generally admitted, where this practice is adopted, that the Onion maggot is conspicuous by its absence. Seed should now be sown in thumb pots, or in boxes, and these may be placed in an atmospheric temperature of 55°. Ailsa Craig and Magnum Bonum are useful varieties for this sowing, although there are several other favourite and up-to-date varieties that are also well adapted for the same purpose. As soon as germination has taken place, let the plants be placed as near to the glass as possible, keeping them there throughout the period they have to remain indoors, gradually hardening them off as growth advances in order to have them fit for transplanting in the open garden early in April.

Lettuces.—Small sowings of the early varieties of Cabbage Lettuce, such as Earliest of All, Commodore Nutt, and Tom Thumb, and of the approved sorts of Cos, should be made frequently in a gentle heat, and if the seedlings are pricked out as soon as they are large enough to handle into good, rich soil, the desired result of a quick return will be likely to follow.

Potatoes.—Keep up a good supply of tubers which have started into growth, and are therefore ready for planting, in order that they may be planted where those that are being lifted for present supplies have grown, and for planting in additional frames or in pots. If "started" tubers are used for planting, not only is much time saved, but a more even crop will be the result.

THE FLOWER GARDEN.

By A. C. BARTLETT, Gardener to Mrs. Ford, Pencarrow, Cornwall.

Ground-work.—If no spring-bedding is done, all the flower beds should now be thoroughly dug. Have plenty of planks at hand for wheeling upon from the walks to the beds. The nature of the manurial dressing will depend on the type of plant allotted to each bed. While in mixed beds it must be decided by the type which will predominate, it will be found best, as a rule, to richly dress the central portion of the bed and gradually diminish the quantity towards the outside. Such strong feeders as Lobelia cardinalis, Dahlias, and those plants in which luxuriance of growth is desired, such as Ricinus, Eucalyptus, and Cannas, should be afforded a good supply of well-rotted farmyard manure. And at the other extreme, with such plants as Pelargonium, Heliotrope, and Begonia semperflorens, where abundance of flower is the chief consideration, a dressing composed chiefly of leaf-mould will be found best. For most bedding plants a good sprinkling of bone-meal worked into the top-spit of soil will be found beneficial, but I am not in favour of applying artificial manures until the plants have established themselves. A watchful eye must be kept on the men while the digging is in progress, as at times there is a tendency to hurry over this work, and the points and corners of the beds suffer. It is difficult to persuade them that the flower garden should be as deeply worked as the kitchen garden.

Carnations.—Beds should now be prepared for receiving the plants which are wintering in frames. The outdoor plants should also receive attention, removing decaying leaves and weeding the beds, also stirring the surface-soil. A

dusting of soot around the plants will promote good colour in the leaves and destroy slugs.

Hollyhocks.—In most gardens the ravages of the Hollyhock disease prevent any attempt being made to grow this noble plant as a perennial, but if seed is sown now in moderate heat, plants can be raised which will flower this year and escape disfigurement to any great extent. Those plants which were raised last year and are wintering in light, airy houses should for a time be still kept on the dry side and frequently examined for any signs of disease. As a preventive measure they should be frequently dusted with flowers of sulphur.

Lily of the Valley.—The beds should receive a top-dressing of well-decayed manure; this should be broken up rather small, or it will impede the growths when the plants commence to come through the surface. From the present time until growth commences out of doors, home-grown crowns will force just as well as imported crowns, and have the advantage of being more fragrant. If it is desired to utilise the home stock, a breadth should be lifted and sorted, retaining the crowns of flowering size for forcing, and with the remainder either make a fresh bed or plant them in such places as the wild garden or at the edge of a wood.

Montbretias.—The older varieties quickly become congested, and it is necessary to lift the corms, at least, every other year. After enriching the soil, replant the largest corms [in a fresh position if another favourable one is available].

PUBLIC PARKS AND GARDENS.

By W. W. PATTIGREW, Superintendent of the Parks and Open Spaces in the City of Cardiff.

Control of Games (continued).—When games are under the direct control of the Parks Department it is necessary to have definite play-pitches marked out and distinctively numbered in each recreation ground where play is allowed. In the case of football and hockey the side boundaries of these pitches need not be more than a few yards apart, but with cricket and baseball, for the sake of safety, the distance from pitch to pitch should never be less than 70 yards.

Notice from Clubs.—It is also essential for the Department to know for a good while beforehand of all the matches for which the grounds are likely to be required from time to time. To secure this information and prevent any misunderstanding we find it useful before the beginning of each game season to have notices posted up in our recreation grounds inviting club secretaries to send us as early as possible a list of their season's fixtures, with an intimation as to which park they would prefer to play in. As these fixture-lists come to hand the dates required by the various clubs, with the different grounds preferred, are entered upon a sheet of double foolscap paper specially drawn up for the purpose. A perusal of this document will indicate in a few moments the number of pitches required in each park on any given date.

Permits are issued to the different secretaries once a month for the use of a pitch for each match (if possible) shown on their fixture card. Each permit has the name of the park where the match is to be played distinctly printed on it, with the date, number of pitch to be used, and the time at which the game starts. Before any play is allowed or apparatus erected, this permit has to be handed over to the man in charge of the ground. To prevent mistakes, this official, each day matches are to be played, receives from the office a form upon which are shown the names of all the clubs playing, the number of the pitches allocated to each, and the time at which play begins. This form is returned to the office with what remarks the keeper may think necessary to insert about any game played, or the conduct of players. If the park keeper is of opinion that the ground is too wet for play, he puts up notices to that effect at all the entrances to the ground in question, and sees that play of no description takes place till it is dry again.

Changes in Programme.—As it would be a matter of impossibility to have fixtures completed at the beginning of the season, it is quite out of the question to allocate pitches all at one time. Clubs have to alter and add to their engagements as the season goes on, as they sometimes find they have to abandon one match and take on another. They keep us informed of the changes, and we act as best we can to meet their requirements, hence our practice of sending out permits at the beginning of each month instead of only at the beginning of the

season. It very often happens that there are more applications for permits for a certain date than there are pitches to dispose of, and it then becomes necessary to discriminate between the various applicants. To avoid friction we always endeavour to distribute permits as evenly as possible among all clubs, and in such a way that no club has a pitch allocated to it oftener than another.

Casual players.—It must not be concluded from the foregoing statement that we only allow organised games to be played in our parks. So long as goal posts are not used, and the ground is in a fit condition, and not about to be taken up for a match, footballers and hockey players can practice as much as they please. With cricket, however, it is different. Instead of allowing indiscriminate play the Parks Department supplies and erects, free of charge, a number of full-sized practice nets in the quietest parts of the grounds, and restricts all cricket practice to these nets. Each division within a net is numbered in the same way as ordinary pitches, and clubs have one of these allocated to them for so many nights a week for practice. Children using soft balls can amuse themselves as much as they please away from the practice ground, but, of course, are not allowed to play over the match pitches, nor during the time a match is in progress. As might have been expected, when we first took full control of the games played in our recreation grounds we had many difficulties to contend against. These have, however, been overcome, and all local "sportsmen" now recognise that it was an exceedingly good thing for sport when the Parks Committee took the step it did. So as to mislead no one who may be desirous of following this example, I may mention, just to show some of the work it entails, that during the 12 months ending September 30, 1906, we issued no fewer than 1,878 game permits, besides a great number of letters and circulars in connection with the playing of games.

THE HARDY FRUIT GARDEN.

By J. MAYNE, Gardener to the Hon. MARK ROLLE, Bickton, East Devon.

Peach and Nectarine trees.—The pruning, cleansing, and re-training of these must now be undertaken, and the opportunity is thus presented of dispensing with any aged or exhausted branch, so that clean young growths from near the base of the tree may have the necessary space for their development, without which it is impossible to maintain a tree with good fruit-bearing wood. The cutting out of shoots in autumn that have borne fruits is good practice, and where this was done there will remain little pruning to do now, except in such cases as mentioned above.

Cleansing the trees.—Scale insects are often troublesome on out-of-door Peaches; these are best removed with an ordinary pot label, especially the large brown scales which usually infest the old wood. In bad cases it is best to go over the whole tree with the label, dislodging as many scales as possible previous to washing. For washing the trees dissolve 12 ounces of soft soap in 4 gallons of warm water, and add a handful of flowers of sulphur and half a pint of quassia extract, thoroughly mixing all together. Keep the mixture constantly stirred during its application to the trees. A sponge, or a painter's soft brush, are useful for rubbing the wood, drawing it towards the points of the young growths, so as to avoid bruising or even displacing the blossom-buds. Should any shoots get broken, prune them back to a wood-bud, which is easily discernible by being more pointed than a blossom-bud. Let the walls be put into good condition by "pointing" the brick or stone-work, and afterwards applying a coat of limewash or colouring. It may not be necessary to do this every year, unless the trees suffered badly from aphid or red spider.

Training.—Spread out the main branches so as to induce a proportionate distribution of the sap over the whole tree. Between these, the bearing-wood should be laid in at from 4 inches to 6 inches asunder. It must be borne in mind that a young shoot will have to be trained in from the base of each present shoot for fruiting in 1908. Whether shreds and nails are used, or the shoots are to be tied to wires, take care to allow ample space in shred or tie for the development of each shoot.

The borders.—Having trained the trees, rake over the surface of the border to remove rubbish,

&c., and if a top-dressing is considered to be necessary, prick up with the garden fork three inches of the old soil, wheeling this away and replenishing with good loam, adding one barrowful of crushed mortar rubble and one of wood ashes respectively to every dozen barrow-loads of loam. If no top-dressing is to be applied, then scatter a thin layer of wood-ashes and bone meal over the surface, pointing this in with the fork as soon as the soil is dry enough for it to be done.

Apricots.—Some gardeners postpone the pruning and training of Apricot trees until the present time, but the sooner it is finished now the better, as the Apricot is the first fruit tree to open its blossoms. "Spurs" should be pruned beyond where they were stopped in summer; short, stubby growths and extension shoots may be left as they are when extension shoots have not made more than 18 inches of growth in the past year. If they have made more than this, then shorten them one-third their length. Apricot trees being so liable to "gumming," it is very important to see that neither wire nor nail

moss, which should be cut up roughly. Keep the plant about on a level with the rim of the pot, with the base of the bulbs just touching the moss, so that the young growths will be free from anything that may cause them to decay. *M. candida* and its variety *grandiflora*—being at rest—should not be repotted until growth recommences. The same remarks apply also to the white-lipped *M. cuneata*, whose flower spikes are now well advanced. The varieties with creeping rhizomes as *M. spectabilis*, *M. Moreliana*, *M. Lubbersiana*, &c., may be grown in shallow, but rather wide, pans as they extend rapidly in every direction. Old plants which may have lost a number of old pseudo-bulbs, and have become ragged in appearance may be divided, all useless pseudo-bulbs cut away and the growing pieces made up anew. Those pieces with but few roots must be fastened down to the compost, as they will not succeed if they are in the least degree loose. All these *Miltonias* grow well in a cool and shady part of the intermediate house. The rare *M. Schroderiana* grows well in the same degree of heat, but requires rather more light. Afford just sufficient water to these

compost about the roots moderately firm, and insert a few large crocks here and there so that water may pass rapidly away. Very little water is needed at the root until the plants start to grow afresh, when the amount of moisture, heat, and ventilation may be gradually increased.

L. Gouldiana, *L. anceps* and its varieties.—It is advisable to keep these plants in the coolest part of the Cattleya house, or if a Mexican house is set apart for them, the atmospheric temperature should be about 55°. Everything that is possible should be done to prevent the new growths from starting prematurely; the later they commence to grow the better the chances are of their blooming satisfactorily. The plants of *L. autumnalis* and *L. albida* should be suspended in the driest part of the *Odontoglossum* house.

PLANTS UNDER GLASS.

By J. G. WESTON, Gardener to H. J. KING, Esq., Eastwell Park, Kent.

Coleus.—A batch of cuttings may now be inserted, either for providing plants to be used in a small state, or for growing into specimen plants.

Acer Negundo variegatum.—Tall specimens of this ornamental-leaved plant, if forced early into growth, give a pleasing effect when placed amongst Palms and similar plants. The Maples need to be removed from the plant house in the summer time, but they can then be replaced by ornamental-leaved Abutilons, such as *A. Sellowianum variegatum*, &c. In large and lofty structures, where small plants appear insignificant, a pleasing effect can be made with plants of *Begonia Rex*, arranged in the form of mounds, carpeted with *Selaginella*, *Tradescantia*, or any other suitable plant.

Eucharis grandiflora (amazonica).—The present is a good time to overhaul these plants, thoroughly cleansing them of insect pests by sponging or spraying. Repot any that require it, but bear in mind that the *Eucharis* generally flowers best when the pot or pan is filled with roots. Healthy plants growing in large pots may be afforded a rich top-dressing, potting only those required for making larger specimens, or that are at present in small pots and require repotting. If any of the plants are in an unhealthy condition, the bulbs should be thoroughly washed out, leaving none of the old, sour soil on the roots. This done, the bulbs should be sorted into sizes, the larger, or flowering bulbs to be potted in large pots of a size considered most suitable in the particular garden, and putting sufficient bulbs in each pot to make a well-furnished specimen. The smaller bulbs should be placed several together in 4½ or 6-inch pots, to be afterwards potted on. The soil for *Eucharis* should consist mainly of sweet, fibrous loam, with all the fine soil shaken from it, but with additions of sand and charcoal. After potting, they should be put into a damp atmosphere of stove temperature, and if a little bottom heat can be afforded them so much the better. As the roots will require very little water at first, great care should be taken that too much is not given, as over-watering is probably the main reason why so many *Eucharis* plants get into an unhealthy condition. For established plants weak soot water is a capital stimulant. I have never practised resting *Eucharis* in cool conditions, as is sometimes recommended, but have always kept the plants in a growing condition. I enclose a photograph of some plants (see fig. 31), which have been grown for nearly eight years in the same stove. Shading from hot sunshine is very necessary, and I have seen *Eucharis* doing very well under the shade of Palms, *Stephanotis*, &c. The finest *Eucharis* I ever saw were grown by a market-grower. The roof glass was shaded with a thick coat of whitewash, the plants were never rested, but several long houses were filled solely with *Eucharis* in the most robust health, and blooming abundantly.

Hymenocallis.—These plants, often seen in gardens under the name *Pancratium*, succeed under similar conditions, with regard to heat and moisture, though requiring perhaps more liberal treatment than *Eucharis*. *H. ovata*, syn. *Pancratium fragrans* is the most popular variety; and *H. macrostephana*, not met with so often, is a beautiful flower that should be included in a collection of these plants.

FIG. 31.—EUCHARIS GRANDIFLORA AS CULTIVATED BY MR. J. G. WESTON IN VISCOUNT DUNCANNON'S GARDEN, BESSBOROUGH, IRELAND.

presses unduly on the branches. Syringe the trees with quassia extract, and give the same attention to the borders as recommended above for Peach borders. The borders containing either Apricot or Peach roots should extend quite 4 feet from the base of the wall.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir TREVOR LAWRENCE, Bart., Burford, Surrey.

Miltonias.—The Brazilian section should now be examined to see if any of the plants require fresh material or additional root-room, this being the proper season to repot them. All the strong-growing varieties as *M. Clowesii*, *M. Russelliana*, *M. Lamarckiana*, *M. Binotii*, *M. Veitchii*, *M. Regnelli*, &c., are best grown in pots which should be well drained with Fern rhizomes. Let the compost consist of American root-fibre (*Osmunda regalis*), pulling this apart into lumps which may be placed firmly among the roots of the plant, covering the surface with a thin layer of sphagnum-

reotted plants to keep the surface moss in a growing condition, but when they commence to flower they should be kept more than ordinarily moist. See that the young roots now pushing from the newest growths are not injured by insect pests.

Laelias.—The majority of the American *Laelias*, as *L. autumnalis*, *L. albida*, *L. Gouldiana*, and those of the *L. anceps* type, will have finished blooming for the season, and before the leading bulbs commence to make new roots the plants may, if necessary, be repotted. It is advisable to avoid all needless disturbance of the old roots, as the plants often fail to bloom satisfactorily the next season. When repotting old-established plants it is not essential to retain more than two or three pseudo-bulbs to one piece which can easily be potted separately or re-made up into compact specimens. For these plants shallow pans or pots may be employed, good drainage is essential, and for a compost two thirds of the best fibrous peat and one third sphagnum-moss may be used, adding a moderate quantity of small crocks and coarse silver sand. Make the

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

Illustrations.—The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY, FEBRUARY 2—
Soc. Franç. d'Hort. de Londres meet.
German Gard. Soc. meet.

TUESDAY, FEBRUARY 5—
Scottish Hort. Assoc. meet.
Nat. Amateur Gard. Assoc. meet.

THURSDAY, FEBRUARY 7—
Linnean Soc. meet.
Manchester and North of England Orchid Soc. meet.

FRIDAY, FEBRUARY 8—
Roy. Gard. Orphan Fund Ann. Meeting and election of candidates, at Simpson's Restaurant, Strand, London, W.C. Friendly dinner in evening.
Roy. Scottish Arbor. Soc. Annual Meeting.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—39° 4'.

ACTUAL TEMPERATURES:—
LONDON.—Wednesday, January 30 (6 P.M.): Max. 42°; Min. 35°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday January 31 (10 A.M.): Bar., 30° 0'; Temp., 36°; Weather—Hard frost.

PROVINCES.—Wednesday, January 30 (6 P.M.): Max. 40° Yarmouth; Min. 35°; Peebles.

SALES FOR THE ENSUING WEEK.

MONDAY AND FRIDAY—
Hardy Border Plants and Bulbs, Roses, Azaleas, Fruit Trees, &c., at 67 & 69, Cheapside, E.C., by Protheroe & Morris, at 12.

TUESDAY—
Clearance Sale of 14 Greenhouses, Piping, Brickwork, &c., at Ashburnham Park Nurseries, 400, King's Road, Chelsea, by Protheroe & Morris, at 12.

WEDNESDAY—
Hardy Border Plants and Bulbs, Lilliums, Azaleas, Rhododendrons, Palms and Plants, at 12; Roses and Fruit Trees at 1.30 and 4; at 67 & 69, Cheapside, E.C., by Protheroe & Morris.
Roses, Plants, Lilies, &c., at Stevens' Rooms, 38, King Street, Covent Garden, at 12.30.

FRIDAY—
Imported and Established Orchids in variety, Orchids in flower and bud, at 67 & 69, Cheapside, E.C., by Protheroe & Morris, at 12.45.

The annual meeting of this excellent society was held at "Simpson's" on January 24, after our issue had gone to press, so that we were unable to chronicle the results of the election. We are now able to mention the names of the successful candidates, and to assert once more that the Society is excellently managed, and, so far as its means allow, doing its work very efficiently. It might do more were it better supported, especially by the gardeners themselves. We trust that in future many more owners of gardens will follow the example of Lady Ilchester and of Earl Beauchamp by throwing open their gardens once a year on payment of a small sum, for the benefit of the institution. The society has, within our recollection, not only made great progress, but it has loosened the shackles which encumbered it and prevented it from accomplishing all the good it was intended to do. Even now it seems anomalous that men who have subscribed for several years, whose claims are beyond dis-

pute, or that the widows of such men, should not be placed by the committee at the first opportunity on the pension list (subject to the approval of the members), but without the formality of obtaining the suffrages of the voters.

All the cases are deserving, but those who have done their best when they had the opportunity to help their fellows should be the first to receive aid when they stand in need of help themselves. Of late years the committee has done something in this direction by crediting such candidates with a number of votes in proportion to the amount subscribed or the special necessities of the case. This is a step in the right direction, but anyone who looks down the list and refers to our report of the proceedings will see at once that there are certain candidates whose claims are so substantial that (assuming that other circumstances permitted) they should have been placed on the list at once without having to trouble their friends, or still more important, without having to wait years before securing the benefits of the institution.

The Victorian Era Fund and the Samaritan Fund render great assistance in these circumstances, and we trust most earnestly that these excellent funds will be largely increased in the future.

It is hardly becoming to report at full length the proceedings at the "friendly supper" which follows the work of the day, because it is understood that this is a private rather than a business meeting, and no one who knows the circumstances will begrudge the members their recreation after the labours of the day. We may, however, comment without impropriety on some remarks made by the chairman as to the necessity of raising the position of some gardeners by a better education, and by a higher general rate of remuneration. It is to be hoped that there are not many "gardeners" to whom the disparaging remarks made by the chairman can apply, but there are some few, no doubt, and these are the very men whose names we should not expect to find among the subscribers to the Gardeners' Benevolent, or to the Orphan Fund.

The British Gardeners' Association, which now numbers 1,000 members, was formed with a view of affording some guarantee of character and competence, and thus of eliminating the incompetent and the undesirable who practise under the name of gardener. It is endeavouring to raise the social standard of the members of the craft by co-operation and other legitimate means. The success or the inefficiency of the charitable institutions are, of course, inseparably bound up with the financial position of the gardeners. As they become raised in the social scale, and as their remuneration is increased in proportion to their responsibilities, so shall we hear less of questionable commissions, and more and more of that self-respect which will cause the gardeners to depend more and more on their own exertions and less and less on the benevolence of outsiders. Larger support will be given to the gardening charities, and more and more power for good will accrue to the British Gardeners' Association.

We may here add that the 68th Annual Dinner of the Gardeners' Benevolent will be held on Wednesday, June 26, at the Whitehall Rooms, Hotel Metropole, when the Hon. Walter Rothschild, M.P., will preside.

OUR SUPPLEMENTARY ILLUSTRATION.—The name under Mr. SMITH's engraving of *Rudbeckia Heliopsis* x was printed as *Rudbeckia Heliopsisidis* under the impression that that was the correct name of the plant figured. We learn, however, that this is erroneous, and that the proper spelling is *Rudbeckia Heliopsis* x. It is unfortunate that two names so closely similar should have been given to two different plants. The following communication from Mr. GUMBLETON, to whom we were indebted for the specimen, gives the history of the plant and shows it to be a hybrid between the old *Rudbeckia* or *Echinacea purpurea* and *Helianthus multiflorus*. If this be really the origin of the plant the case is one of great interest:—

"I received a plant of this hardy Composite (the Red Sunflower) towards the end of 1905 from its raisers in Germany, Herren KOHLER & RUDELL, of Windischleuba, Altenburg, who assert that it is a hybrid resulting from the cross fertilisation of *Helianthus multiflorus* with *Echinacea purpurea*, and they have named it the Red Sunflower. It bloomed freely in my garden during last summer, producing about 30 flowers. I was somewhat disappointed with the colour, which could hardly be called red, but the large number of flowers, most of which opened simultaneously, made it a very showy object in the garden. I had previously tried to raise it from seed, but could not get them to germinate." W. E. Gumbleton.

NATIONAL CHRYSANTHEMUM SOCIETY.—The secretary informs us that the annual general meeting of the members of this society will take place at CARR's Restaurant, 264, Strand, W.C., on Monday next, February 4, at 7 o'clock in the evening. CHARLES E. SHEA, Esq., president, will preside. Agenda: To receive the executive committee's annual report and accounts for the year 1906; to elect officers for the year ensuing; to consider, and, if approved, to adopt, the new rules of the society as per draft circulated among the members; to transact such other business as pertains to the annual general meeting.

GEO. MONRO, LTD., CONCERT.—The committee informs us that the 11th annual concert will be held on Thursday, February 21, at the Queen's Hall, Langham Place. GEO. MONRO, Esq., will preside. From the cash statement of the results of the concert held on February 22, 1906, we learn that the following donations were given to charities: Ten guineas were given to the Gardeners' Royal Benevolent Institution, six guineas each to the Wholesale Fruit and Potato Trades Benevolent Society, and to the Surgical Aid Society, five guineas to the Charing Cross Hospital, three guineas each to the Royal Ophthalmic Hospital, and to the Covent Garden Lifeboat, and two guineas to the GEO. MONRO, Ltd., Pension Fund, and the GEO. MONRO, Ltd., Outing Fund, total £88 17s. The total gross receipts from the concert were about £200, and the expenses £160.

PRESENTATION TO A GARDENER.—Mr. W. McCOLL, bailiff and head gardener to Sir MARK COLLET, Bart., was presented with a clock by his fellow employees, at St. Clere, on Wednesday, January 16, on his leaving St. Clere to enter the services of Mr. J. CLIFFORD CORY, at Llantarnam Abbey, Monmouthshire.

LINNEAN SOCIETY.—The next general meeting will be held at 8 p.m. on Thursday, February 7, 1907. Papers:—1, Dr. OTTO STAFF, F.L.S., "New Plants from Malaya"; 2, Mr. F. CHAPMAN, A.L.S., "Tertiary Foraminifera of Victoria—The Balcombian Deposits of Fort Philip." Exhibitions.—1, Messrs. H. & J. GROVES, F.L.S., Specimens of *Chara ornithopoda*; 2, Rev. JOHN GERARD, S.J., F.L.S., Some Observations of Climbing Plants (with lantern slides); 3, Mr. W. ROSE SMITH, Herbarium formed by A. Ruperti, 1638-1700.

THE RED-SUNFLOWER, *RUDBECKIA HELIOPSIDIS*, FROM THE COLLECTION
OF W. E. GUMBLETON, ESQ.

THE PREVENTION OF CORRUPTION ACT.—We have received from two separate sources a copy of the following circular, sent to gardeners and emanating from a well-known German seed firm:—"Herewith I have the pleasure of presenting you my new general seed catalogue which I recommend to your kind notice. As the direct demand for my Erfurt seeds in consequence of their excellent quality is increasing from year to year in England, I take the liberty in offering a bonus of 10 per cent for all orders kindly entrusted to me, and 20 per cent, if amount of invoice exceeds £5. All my seeds uphold the standard of superiority, and must not be confounded with the average quality in the trade which are very profitable for the dealers, but are disappointing to the sower. Thanking you in anticipation for your kind orders. It is necessary to caution all agents and gardeners that the receipt of such 'bonuses,' if not made known to the principals, will be attended with great risk of severe penalties."

BRITISH GARDENERS IN THE UNITED STATES.—We lately published, by the courtesy of Mr. WALLACE, a list of horticulturists who had migrated from the mother country to the United States and achieved eminence in their new abode. We have often regretted that we hear so comparatively little of the doings of those who have left our shores, and that, whilst we are familiar with the doings of the few at the top of the tree, we hear relatively little of those perhaps equally good men, but not so well known to the horticultural public. Amongst others we note the following:—**ALFRED LOVELESS**, President of the Chrysanthemum Society of America; born September 26, 1866, at Langford, Somerset, went to the United States in 1889. **JOHN K. M. L. FARQUAR**, born at Fyvie, Scotland, on July 23, 1858. He was an old Chiswick student, and is now one of the directors of the Society of American Florists and "Ornamental Horticulturists" (sic).

DR. HERBERT WEBBER, who visited this country at the time of the first Hybridisation Conference, and has for some years been connected with the Government Bureau of Plant Industry at Washington, has accepted a professorship in the Cornell University. His duties will have special reference to experimental work in connection with horticulture and agriculture.

NO MORE "POD-BURSTERS."—To obviate the unsightliness of the split calyx, Messrs. MAXFIELD & DIMOND, of Warren, R.I., have, says the *American Florist*, invented a sheath which is slipped over the bud and prevents the splitting of the sepals. Our contemporary adds that it has examined this artificial calyx, and "considers it the simplest and most feasible device of this character that we have seen."

THE AMEER OF AFGHANISTAN.—The AMEER OF AFGHANISTAN is a great gardener, and under direct orders his agents lately in England have placed extensive orders for the complete equipment of his garden according to the most up-to-date ideas, from an improved spade to the choicest of products. Messrs. CARTER, the King's seedsmen, of High Holborn, have received instructions to make a large shipment in this direction, the Ameer himself having marked down in their books many of the specialities that he is anxious to have tested in the Palace gardens at Kabul, previous experiments having proved so successful. Special parcels have also been made up for distribution among the Court officials at Kabul. At present the Royal gardens are arranged according to Western ideas, and the surroundings have become quite picturesque owing to the plantings of trees made some years ago by the English gardener sent out by Messrs. CARTER & Co.

RESEARCH.—The following remarks by Mr. HALL, the director of the Rothamsted experimental station, at the Society of Arts, apply in their degree as much to horticulture as to agriculture and are specially applicable now that a start is being made at Wisley.

"What provision is this country making for adding to the stock of knowledge at the service of the farmer? A start has indeed been made in the direction of education, but the necessary preliminary to education is research. The teacher can only hand on what is already known, and there is much yet unknown about the growth of our commonest crops and the action of our standard fertilisers. Only by continued investigation and experiment can a knowledge be obtained of the conditions necessary to make the maximum profit out of our land, our crops, and our stock. What provision then is the country making for research in agricultural matters? Well, I can only tell you that the grants of our Board of Agriculture for agricultural research during the past year amounted to £425, while the corresponding grant in the United States of America (salaries and administration expenses being excluded in either case) was more than £200,000. Looking at the various yields of the various countries of the world we find that Great Britain is the most intensively farmed country; it contains the biggest crops per acre, it has to spend the most to obtain them. Furthermore, the bigger the crop the greater are the risks of disease and blight, and the greater are the difficulties in securing high quality. Here then in Great Britain exists the greatest need for knowledge and investigation; nor can we always beg knowledge from wiser countries, for many of our problems are special and brought about by the very conditions of high farming which prevail here. England was the first country to start an experimental station, yet Rothamsted still remains the only institution solely devoted to agricultural research in the British Isles, if we except the farm of the Royal Agricultural Society at Woburn. The income of the Rothamsted station, derived from private benefaction, is about £2,600 a year; in the United States each of the 53 States possesses a station receiving £3,000 a year from the Federal Government, in addition to what the State itself may contribute, while there is also the great Central Department of Agriculture, of which I have already spoken. Yet Rothamsted cannot obtain a grant from the Board of Agriculture to extend its operations; the country is too poor, agriculture too unimportant an industry."

CHRYSANTHEMUMS AND HOW TO GROW THEM FOR EXHIBITION.—When a book reaches a fourth edition, pretty good evidence is afforded that the publication has justified its existence. This is the case with the little work above mentioned which is published at the cost of 1s. by Messrs. Collingridge, 148, Aldersgate Street, E.C. The title explains the limitations the author, Mr. J. B. WROE, has imposed upon himself, and the preface explains the author's views at fuller length. We have then an excellent practical treatise on the culture of the plant for exhibition purposes. The multifarious details, the times at which they should be carried out, are all explained fully and stress is laid upon the kinds that do well in the south but not so well in the north, and *vice versa*. Lists of appropriate varieties are provided, as well as copious tables, a few illustrations and an index. We could have wished a fuller account of the important subject of bud-variation as illustrated by the several "breaks" and the process of "taking" the buds, but the limitations of the book afford us no right to complain of a book intended for exhibitors only. We can only hope that someone with sufficient competence and skill will undertake the study of bud-development as shown in the Chrysanthemum, as we are sure that the results would not only be of scientific interest, but would eventually facilitate the labours of the growers.

SAN FRANCISCO.—The florist's business is recovering after the earthquake and fire. All the old firms have, says the *American Florist*, resumed business, and several new ones have appeared, amongst them four Japanese establishments.

FIRE AT A WOKING NURSERY.—Damage to the extent of between £350 and £400 was done by a fire at the Goldsworth Nursery of Mr. W. C. SLOCOCK, in the early hours of Sunday last. The outbreak was first observed about one a.m., by a lady, from a bedroom window of The Beacon, which overlooks the nursery, and her husband immediately ran to arouse Mr. SLOCOCK, who telephoned for the Woking Fire Brigade. A large quantity of nursery stock, comprising some 55,000 plants, chiefly fruit trees, packed ready for dispatch, was either destroyed or damaged, together with a waggon, tip cart, spring cart, and many bales of peat moss. The origin of the fire is unknown, Mr. SLOCOCK's loss is partly covered by insurance.

A TREE'S HISTORY.—One of the giant trees of California [Wellingtonia], whose pictures adorn a good many advertisement boards, was cut down some time ago, and on examination revealed a most instructive history of the forest fires, which had swept the region where for more than 2,000 years the trees had existed. The effects of fires occurring centuries ago are registered in the trunks of trees, and the record is completely concealed by subsequent healthy growth. The tree had an enormous burn on one side, 30 feet in height and occupying 18 feet in its circumference. This burn was due to a fire which occurred in 1797, and the tree had therefore occupied more than a century in its efforts to repair this injury, its method being ingrowth of new tissues from the margin of the great black wound. The tree began its existence in about 271 B.C., and in 245 A.D. occurred a burning on the trunk 3 feet wide. This fire took place therefore in its 517th year. A hundred and five years were occupied in covering this wound with new tissues. For 1,196 years no further injuries were registered. In 1141 A.D., at 1,172 years of age, the tree was burned a second time in two long grooves. Each had its own system of repair. In 1580 A.D., at 1,851 years of age, occurred another fire, causing a burn on the trunk 2 feet wide, which took 56 years to cover with new tissues. Two hundred and seventeen years of growth followed the burn. In 1797 A.D. occurred the tremendous fire which burned the great scar of 18 feet wide. In the hundred odd years which have since gone by, the tree had been repairing the burn, and had reduced the exposed area by about 4 feet of width.

MR. HOLMES' COLLECTION OF ALGÆ.—Through the generosity of Mr. W. A. CADBURY, the large collection of Algæ made during the last 30 years by Mr. E. M. HOLMES, F.L.S., Curator of the Pharmaceutical Society's Museums, has been acquired for the botanical department of the University of Birmingham. The collection includes about 13,000 specimens, and has the reputation of being, apart from the national collections at the British Museum and Kew, the best collection of Algæ in the country. The collection has been made by Mr. HOLMES in his holidays during the last 30 years. It is, as we learn from the *Pharmaceutical Journal*, essentially a collection of authentic specimens carefully selected and mounted so as to show the character of the branching; each variety and each form of fructification in any species receiving a separate sheet to itself and every variety of a species obtainable being represented. When Mr. HOLMES began the study of marine Algæ only 400 British species were known, but the number of British species has now been raised to 750. Mr. HOLMES' collection of British Lichens, probably one of the best as regards rarity and beauty of specimens ever made, is now in the possession of the Nottingham University College Museum, and his collection of Mosses, largely representing those of Devon and Cornwall, passed some years ago into the possession of Cambridge University.

EVESHAM GROWERS AND FRUIT-PESTS.—Some representative fruit-growers and market-gardeners of the Evesham district met at the Town Hall, Evesham, on January 23, under the presidency of the Mayor (Mr. W. A. FISHER), to consider a proposal to revive the old Evesham Fruit-Pests Committee. Mr. T. E. DOEG, a member of the old committee, referred to the good work done by that committee which was organised in 1890. It was then quite a common occurrence to see large areas of Plum trees as bare of leaves at midsummer as in the winter, owing to the unchecked plague of the winter-moth caterpillars, for grease-banding had not then been properly and systematically carried out, and no other means had ever been adopted to protect the trees against other pests. It was through the old committee that systematic grease-binding in the winter months was generally adopted in the districts with the auxiliary use of spraying in spring or early summer. With the advantage of improved methods a committee might carry on investigations which could not fail to prove of immense value to the fruit-growing industry. Mr. W. MASTERS said he believed the future of fruit-growing was very largely dependent upon work such as was proposed. It was not only a question of preserving the crops, but they had to consider the quality of the fruit which pests so much affected. Mr. H. BASTIN POLLARD suggested the consideration of frosts, bullfinches, silver leaf, and the borer as subjects [of investigation] for the committee. Mr. G. F. HOOPER said that it might be advisable for the county authority to assist them to retain Mr. THEOBALD or Mr. COLLINGE as experts, so that they might have the highest professional opinion. Other suggestions were offered, and ultimately a committee of 14 was elected, and it is understood they would consider the question of rules, officers, and the constitution of the new body generally.

ACACIA (MIMOSA) FOR THE ENGLISH MARKETS.—Large quantities of Acacia sprays at this season find their way to our markets and florists' shops. These come chiefly from the South of France, whence, in 1903-1904, 500,281 packages were despatched between December and April. On an average, says the *Revue Horticole*, the small growers along the French Riviera obtain for their flowers generally an annual revenue of about 4,000,000 francs (£160,000). The species principally cultivated, under the misleading name of Mimosa, are *Acacia floribunda*, which comes into the market from November to February, and *A. dealbata*, which comes in a little later. Nice, Cannes, Hyères, and Venice are the principal stations whence quick flower-trains are despatched, *via* Boulogne, to London. At first the growers depended on specimens growing in the open air, of which so many may be seen in the public gardens at Nice and elsewhere. Now, a common practice is to cut the flowering branches before the flowers expand, place them in jars of water in a dark place, and exposed to a temperature of 28° to 30° C., (84° to 86° F.). At the end of 24 or 36 hours the flowers are sufficiently expanded. In other cases forcing is carried on in low pits warmed and shaded. Care has to be exercised in choosing the branches for forcing, those in the centre of the tree away from the sun are the best for early work. If when the buds are squeezed in the hand they readily fall to pieces, they are in a fit state to be forced. Those which are not thus disintegrated must be forced at a later date. Forcing is generally begun at the beginning of January. The trees are propagated by offsets from the roots, especially from those species which are known to flower early. In order to promote the production of these offsets the lateral roots are twisted or sliced longitudinally, and a small narrow portion of the bark removed. The price obtained in the London market varies, according to the season,

from 2.50 to 7.50 francs, and even 12.50 francs per package weighing 5 kilos. (11 to 12 lb.). The package is sold with the flowers. It is said that the London dealers forward the packing material to the growers and deduct the cost from the produce of the sales. The salesmen charge a commission of 10 per cent. plus the cost of transport from Boulogne to London. The freight from Nice to Boulogne is paid by the growers. Packages leaving Nice on Monday at 1 p.m. arrive in Covent Garden at about 5 a.m. on Wednesdays, *i.e.*, in less than 40 hours. There is no Customs duty to be paid here on these packages.

GERMAN HORTICULTURAL EXHIBITIONS.—**MANNHEIM** is preparing an extensive horticultural exhibition this year from May 1 to October 20. The town of Mannheim is situated on the Rhine where the Neckar falls into that river, and is only half an hour from Heidelberg, known for its old castle, and an hour's drive from Darmstadt, a well-known place for modern art and horticulture. Mannheim is on the direct route from Mayence and Frankfurt to Baden, Karlsruhe and Switzerland. Very considerable funds are guaranteed, and the town of Mannheim is preparing an exhibition combining art and horticulture. There will be not only a permanent show, lasting all the summer in the grounds, but nearly every week there will be special shows of Orchids, flowers, fruits, and other products of the season. Art and horticulture will be united in laying out a number of gardens in different styles. A large water-garden will serve to display all kinds of *Nymphæas*, many up to this time not known to horticulture and botany. Many houses will be filled with Palms, Victoria regia and *V. Cruziana*, Orchids, *Nelumbiums*, &c. The large hall, the Rosengarten, besides other large halls, are prepared to open their doors to the horticultural products of the whole country. From May 7 to 9 the first international Orchid exhibition will be opened. Roses will be specially well shown at Mannheim, besides very many not specially mentioned.

DRESDEN.—A large international horticultural exhibition will also be held at Dresden from May 4 to May 12, so that it will be possible for the visitor to Germany to see both these exhibitions in one journey.

THE ROYAL AND IMPERIAL HORTICULTURAL SOCIETY OF VIENNA.—The project of instituting a permanent exhibition of plants in the society's buildings, which are conveniently situated on the "Ring" in the centre of the city, has for some time been under discussion, and it came before a general meeting of the gardeners of the vicinity and members of the trade in November in a concrete form, the following proposals being made by the landscape gardener, Herr JOHANN ZOPF:—(1) That for the purpose of a permanent exhibition the glasshouses (cold and warm) and pits and frames, as well as a portion of the reserve garden, should be set aside by the society. (2) All plants brought before the members, on the *Sprechabenden* (evenings for discussions and speeches), also inclusive of novelties of special interest, would be on view in these glasshouses free of charge. (3) In recognition of deserving novelties of the exhibitor's own raising, first, second, and third-class certificates would be awarded by the committees concerned, these certificates being awarded on the occasion of the annual distribution of prizes. (4) The cost of carriage to the society's premises to be defrayed by the sender, and that of their return, if outside of Vienna, to be paid by the society. Seeing that the society's glasshouses, offices, &c., are situated in the heart of the town, and readily reached from all points, it is expected that horticulturists will visit these permanent exhibitions in considerable numbers, their attention being directed to

them by the trade journals. At the present, everything is vague and indefinite, and it is yet too soon to prophesy.

INCREASED PRIZES FOR VEGETABLES AT THE SHREWSBURY EXHIBITION.—Growers and exhibitors of vegetables will learn with exceeding interest that the committee of the Shropshire Horticultural Society has agreed to put these products on a higher plane this year in relation to prizes than they have hitherto occupied. At Shrewsbury, plants, flowers, and fruit have long been encouraged by magnificent prizes; now vegetables are to be similarly honoured. The Society's class for 12 kinds, for which the prizes hitherto have been £4, £3, and £2, will now have prizes of the value of £10, £7, £4, and £2. The Shropshire county class will also have its prizes increased in value. But to prevent any diminution of competition in the trade-classes for vegetables, hitherto the chief classes in this section of the exhibitions at Shrewsbury, not only will each one be for nine kinds to make all equal, but a special prize of 10 guineas will be given for the best collection in these trade classes. This is certainly most liberal encouragement.

Publications Received.—*Annual Report of the New Zealand Department of Agriculture.* This, the 13th annual report (for 1906), is a bulky tome of which Mr. T. W. Kirk is editor, and he is also responsible for the divisions of biology, horticulture and publications. A wonderful amount of work is carefully chronicled. The book now contains many illustrations.—*The Agricultural Gazette of New South Wales.* December, 1906. Contents: Typical varieties of wheat grown in N.S.W., F. E. Guthrie; Rhodes Grass, J. H. Maiden; Water Hyacinth in N.S.W., &c.—*Le Moniteur du Jardinier*, 20th January. University of Illinois Agricultural Experiment Station. Urbana, November, 1906. Circular No. 105.—*The Duty of Chemistry to Agriculture*, by Cyril G. Hopkins.

FORESTRY.

FORESTRY AT THE UNIVERSITY OF OXFORD.

THE latest addition to the University, the forestry branch, is developing rapidly, as the following data will show. There are now 56 students of forestry at Oxford, namely:—First-year students, 27; second-year students, 16; third-year students (on practical work), 13. Of these students, 43 will go to India, two to an Indian native state, eight to the Colonies; two are private students for the diploma (both having already taken their degree), and one is an Alsatian. During the year 1907 18 additional probationers will be appointed, by nomination, on the recommendation of a selection committee. Candidates must, on July 1, 1907, be over 18 and under 22 years of age. They must send in their applications not later than July 1, 1907. Full particulars can be obtained from the secretary, Judicial and Public Department, India Office, London, S.W. The Professor of Forestry, Dr. Schlich, at 29, Banbury Road, Oxford, is ready to advise any candidates. *Times*, January 28, 1907.

THE DOUGLAS FIR AS A FOREST TREE.

PRINCE BISMARCK showed me his Douglas plantation at Friedrichsruh when I was staying with him in September, 1889, shortly before his "fall." Those at Varzin I never saw. The Chancellor was specially proud of a curiously thick patch of "Douglas," then about 10 years old. Never had I seen Conifers, except self-sown Scotch, so thick upon the ground.

In reply to your editorial request for opinions as to "variations" and "rate of growth," may I add that warning against the Colorado variety [except for ornamental purposes] is needed, inasmuch as "Douglas" is Douglas to a British Crown forester, and this slow-growing blue or glaucous variety is mixed with the vivid green Californian or "Pacific-slope" Douglas in some recent plantations. D.

THE PROPAGATOR.

THE period is approaching when there will be a renewal of growth at the roots of most indoor subjects, and the plant-propagator will recommence his labours after a two months of almost enforced inactivity in this department of gardening. A few remarks may therefore be considered appropriate in regard to the pots, pans, &c., used for the reception of the cuttings. The receptacles may either be small pots, from 1 to 2 inches in diameter, or shallow pans, of widths varying from 4 to 8 inches in diameter; and in order that the cuttings shall have no large amount of soil beneath them, holding much moisture, and tending therefore to promote decay in the cuttings, the height of a seed or cutting pan should not exceed 3 inches, and it should be furnished with a central outlet and several others at the side, quite close to the bottom.

Pots and pans of greater diameter and depth than those named should not have the central

be placed, and pressed evenly and firmly, then the soil, and finally the sand layer. The proper rule to follow in affording soil is to choose that in which a plant is known to grow best, and to add to this a certain proportion of clean sand. The last layer, the sand, should be as clean as it can be obtained, or, failing that, it should be cleansed in several waters before use. The soil should be moderately moist, as a dry soil does not usually set closely around a cutting, and a wet soil sets too tightly, hindering the progress of the tender rootlets, shutting out the air, setting up disease, and ultimately bringing about the death of the cutting.

In general, the soil has less influence on the formation of roots than warmth, moisture, and light. Perhaps the best kind of soil for filling pots, pans, boxes, &c., consists of the finer part of turfy loam, which should be used to the extent of three-quarters the depth of the vessel, over which the layer of sand should be placed, first affording the soil a thorough application of water

as regards its size to the plants over which it is placed; accordingly, big bells should not be placed over a few small cuttings, as these would be more difficult to root than in the company of many.

Instead of being obliged to use many bell-glasses and *cloches*, small, low cases, fitted tightly with glass lights, can be used, these being stood in the propagating house or other suitably-heated structure.

No cutting should be placed in a house or frame having a higher temperature than the species requires for its natural development. When a cutting is placed in a structure that is too warm, and where a moist atmosphere is constantly maintained, the tissues grow with too great rapidity, the vitality of the cutting is soon exhausted, and it then becomes soft and watery, the leaves thin in substance, and it probably perishes. A too low degree of warmth brings other evils in its train. A certain amount of warmth is needed by cuttings of every kind of plant; the immediate effect of which is to

FIG. 32.—VIEW IN THE "SEEDLING" ORCHID HOUSE OF MESSRS. W. BULL AND SONS, CHELSEA.

(See note by Mr. de Barri Crawshaw in the issue for January 12.)

be covered with a convex crock, but with an inverted pot of small size, commensurate with the size of the pot or pan, the bottom of the inverted pot being level with the surface of the soil. This pot serves as a reservoir of water, for the benefit of the cuttings, and, in the case of a hot-water heated propagating bed, for the passage of heat from the chamber underneath it into the house. The cuttings being inserted in circles around the inverted pot are easily separated when rooted without injury to the roots.

Some propagators, instead of the inverted pot, make use of a little cylinder of charcoal in the middle of the pan or pot and as high as the soil is deep. For the wholesale propagation of plants, "cutting" boxes of wood, 3½ inches deep, and from 1½ to 2 feet in length, furnished with numerous holes bored in the bottom, may take the place of pans.

In order to prevent the souring of the soil a layer of sandstone, broken into pieces, about the size of horse beans, should be placed at the bottom over a few hollow crocks. Above the sandstone a layer of chopped woodland moss should

be placed, and pressed evenly and firmly, then the soil, and finally the sand layer. The proper rule to follow in affording soil is to choose that in which a plant is known to grow best, and to add to this a certain proportion of clean sand. The last layer, the sand, should be as clean as it can be obtained, or, failing that, it should be cleansed in several waters before use. The soil should be moderately moist, as a dry soil does not usually set closely around a cutting, and a wet soil sets too tightly, hindering the progress of the tender rootlets, shutting out the air, setting up disease, and ultimately bringing about the death of the cutting.

PROPAGATION IN BELL-GLASSES.

For the propagation of some kinds of plants from cuttings, bell-glasses are a necessity; and experience has proved that those of a blue or violet colour favour the development of roots. For covering a number of small pots, the wide half-globular form, with or without facets, and in three or four different sizes, is suitable. There are low bell-glasses for covering small things as *Epacris*, *Erica*, *Leschenaultia*, &c., which are more useful when furnished, at the top, with a hole instead of a solid knob. Cuttings of valuable, tender plants are rooted with greater certainty when a bell-glass is employed to cover each cutting of a suitable size, and the rims must be pressed into the sand, so as to quite exclude the air.

The bell-glass should always be proportionate

induce cell-activity, resulting first in the formation of new growth of roots and then of leaves and shoots.

ROSES AND CONIFERS.

Roses.—The grafting of briar stocks for forming standards, half standards, and dwarf bushes may now be commenced; the stocks for the last-named being seedlings of two years old, with stems as thick as a goose quill. The method of grafting may be whip, side, or crown, and in the case of the last-mentioned, two scions may be inserted in the cleft of strong briar stocks. A scion may have a length of 3 to 4 inches, and consist of ripened wood of the previous year. The stocks should have been potted in October, or early in November, and have been placed in a warmth of 55° three weeks before being grafted. The grafts should be secured with worsted or raffia, and a coating of grafting wax applied warm. Genial warmth should be maintained, and a daily syringing afforded the stocks, and water at the root when needed. When it is observed that a union has been effected, place the plant

in a warm greenhouse, remove all foreign shoots, and in a few weeks cut the ligature holding the graft. The new plant will now make several shoots, and flower well in the spring months, and again late in the summer. Manetti Rose stocks may likewise be grafted now, or on pieces of the roots of cuttings and seedlings 6 to 12 inches long; packing these away in damp soil till later.

Choice coniferous plants may be wedge or cleft-grafted on some common conifer stocks established in pots in early autumn, or the previous spring. "Head-down" the stock to a height of 1 foot, and reserve a small number of needles near the top, removing the others below, for a space of 2 inches, to allow the ligature to be passed round the stock. Keep the grafted plants in a close case in a warm house till a union takes place.

BEGONIAS AND SUCCULENTS.

Begonia Rex, and other species, and *Pachyphylum* may be propagated from leaf cuttings placed in amply-drained pans and on sandy soil, stood on a light shelf in a warm house. The propagation of *Echeverias* and *Sempervivums* for flower-garden purposes should now be commenced; making use of cuttings of shoots, of leaves, and off-sets. Very little, if any, warmth is required, and moisture must be continuously applied.

GARDENIAS, &c.

Cuttings may now be taken of *Gardenias* of species, employing fairly mature shoots of 4 to 6 inches in length. These root freely in a warm sand-bed, or in one consisting of sifted loam and sand. The top heat should not exceed 65° at night, and the bottom should not be below 80° to 85°. *Tabernaemontana coronaria* may be similarly increased.

Seeds of Palms, spores of various ferns, and seeds of *Begonias* may all be sown towards the end of the month on a bed with a bottom heat of 80°.

Ixoras and *Correas* may be grafted: and to

annuals of the stove and greenhouse may be sown this month. They require a bottom heat of 75°, and 10° less top warmth.

Vine eyes may be struck this month on 2-inch squares of tough turf, or in pots (60's) on a

TWO NEW ODONTOGLOSSUMS.

Our illustrations represent *Odontoglossum caloglossum* (fig. 33) and *O. "Ruby"* (fig. 34), for each of which Monsieur Charles Vuylsteke, of Loochristi, Ghent, was given an Award of Merit at the

FIG. 34.—ODONTOGLOSSUM "RUBY."

bottom heat of 80° and a top heat of 65°, and best in a frame on an ordinary hot bed. There are other plants with large, leathery leaves, which may be propagated from "eyes" like

Royal Horticultural Society, on January 22, the two varieties illustrated being the best of an interesting selection shown by M. Vuylsteke on that day. The ground colour of the sepals and petals in each variety is pale lilac, the blotches being reddish claret colour. The lips are white with rose-purple spotting and yellow crest.

LAW NOTE.

ACTION FOR WRONGFUL DISMISSAL.

At the Croydon County Court on January 17, Albert Brooks, of 3, Rectory Road, Surbiton, gardener, sued the Rev. Arthur Tooth, of Woodside, for £4 16s., one month's wages alleged to be due in lieu of notice.

Plaintiff's claim was based on an agreement signed by the defendant engaging to employ him as head working gardener at a weekly wage of 24s. subject to a clear 28 days' notice. He admitted that he agreed to live at the lodge, and said that when he entered defendant's service on the Monday he discharged him immediately because he had not previously sent his furniture into the house.

The defence was that the man practically severed his engagement through not having brought his furniture to the lodge to live there, as agreed, but the Judge did not regard this as sufficient grounds for dismissal. He gave judgment for plaintiff for £1 7s.

NEW INVENTION.

PROTECTING BUDS FROM BIRDS.

Mr. H. J. Hewett, 4, St. Clement Street, Winchester, sends for our inspection a tool for fixing cotton on Gooseberry and other bushes. It is made on the same principle as a fishing rod, the reel of cotton being fixed at the end nearer the operator, and the cotton runs down the rod in a groove beneath hands, finally passing through a ferrule at the extreme end. The length of the rod is a little over two feet. With the aid of this little implement a Gooseberry bush can be quickly protected with cotton, and without injuring the hands.

FIG. 33.—ODONTOGLOSSUM CALOGLOSSUM.

promote a union, place the plants on a mild bottom heat. The *Correas* by preference should have as a stock *C. alba*, a vigorous grower, and therefore very suitable. Numbers of tender

Vines, namely, *Magnolia fuscata*, *Wisteria chinensis*, *Hydrangea*, *Pyrus*, *Vitis* of species, *Morus*, *Dracæna*, *Cycas* (from scales), *Pittosporum*, &c. *F. M.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

THE "NATIONAL" POTATO SOCIETY.—It certainly looks, judging by your report of the recent meeting of members of this society, that it was near its end. That is much to be deplored, whatever may be the outcome of the resolve to hold an exhibition and conference at Wye College next autumn. Starting some two or three years since, the society was so unfortunate as to be associated, though more by certain trade members than by its officials, with that most disastrous incident in Potato business, the immoral "boom," inaugurated just then over certain novelties, and which, after creating a great sensation, had the result of making interest in Potatoes go up like a rocket, and soon to fall like a stick. It is that sense of disgust in the public mind which has done so much to help kill the Potato Society. One grave defect in its operation was that it depended too much for support on the Potato trade, thus to some extent becoming rather the organ of the trade than of the private or amateur grower. How very much in that respect it differed from the old International Potato Society, which did its utmost to promote Potato culture among all classes, and created quite a small army of gardener, amateur, and cottager supporters and exhibitors. Any Potato society, so be worthy the name "National," can exist on such lines only. If we look at the *climble* of some other special societies, we find how strong is the support given to them by the private growers as distinguished from the trade, although in no case does the trade exhibit a desire to monopolise interest, or to control any one society's operations. Based upon such broad lines these societies may go on rendering good service to floriculture for generations. It is in such lines we wish to see a Potato Society based. But there has been strongly expressed a desire to originate something wider in its operations, and that is a Vegetable Society, of a national character, and which would, if existent, necessarily make the Potato a prominent feature. Special societies exist in the interest of several flowers, and with marked success and striking results. Even root vegetables and horticultural products of even greater importance to us than are flowers? Most certainly they are. Why not, then, a great National Vegetable Society, holding its exhibitions annually, especially in London, where is found the greatest body of consumers in the world, and yet these people seldom or never see, as can be seen in so many provincial towns, what real vegetable exhibitions are. *A. Dean.*

PRIMULA × KEWENSIS.—It is interesting to note how true this winter-flowering Primula comes from seed; judging from a good batch we now have in flower it is as reliable as the best strains of *P. sinensis*. Several growers I know have experienced a difficulty with plants propagated by division during the summer months. Seedlings are much more vigorous. If given a cool, moist, and shady position they make growth freely, and if occasionally sprayed with XL-All plant wash the leaves keep clean and free from insect pests. As a decorative plant it compares most favourably with any of the Primula family; arranged with small single-stemmed plants of *Coleus thyrsoides* they are very effective, and make a good display during the dull months of the year. Being so easily raised from seed, *P. × Kewensis* should become as popular as the other winter and spring-flowering Primulas, owing to the beautiful golden colour of the flowers and the freedom in which they are produced. *H. S., Bournemouth.*

PHEASANTS AND PLANTS.—Here the numerous pheasants do not interfere with Gunneras, neither do they seem to care for *Lilium auratum*, *Crocuses*, *Broccolis*. They have, however, a decided liking for Carnations, and despite careful watching, and frightening them on every possible opportunity they devour the foliage, leaving nothing but bare stems. They will lie quiet when anyone is about, it directly they are left alone will recommence their feast. It is possible the rabbits get wrongly blamed for sometimes eating the foliage of Carnations quite bare. It would be interesting to know if any *Chronicle* readers get their Carnations destroyed in the same way. *J. S., Mulroy Gardens, Donegal.* [Sparrows are very troublesome to carnations. Ed.]

FROST IN CORNWALL.—On January 22 we experienced a sharp and sudden frost, which continued three days and nights, and greatly injured many sub-hardy plants. Fortunately, we had protected some of them with dry leaves, but *Ceanothus azureus*, *Hedychium*, *Agaves*, *Chrysanthemums*, *Calceolaria*, *Burbridgei*, *Cilanthus*, *punicus*, *Yucca gloriosa*, &c., felt the cold severely. Some of these last mentioned, which have long branches, drooped, and many of them which were not supported in time snapped; 9° of frost is unusual here. The *Rhododendrons* are late. Unlike the *R. barbatum*, mentioned in *Gardeners' Chronicle* of January 26, the plants here show no signs yet of flowering. *Pyrus japonica* is flowering well against a wall, and true to time are the Snowdrops, winter Aconites, *Iris reticulata* and *I. stylosa* flowering since the rise in the temperature. *H. W., Trevinice.*

RAINFALL IN CO. DOWN.—The following rainfall was taken at Seaford House:

Month.	19.0	1901	1902	1903	1904	1905	1906
January	2.97	3.85	2.09	5.14	8.05	1.85	3.97
February	4.18	1.46	4.17	3.15	4.84	1.70	2.05
March	1.90	2.81	1.77	5.29	2.41	4.07	1.97

RUBUS.—*R. quentlandicus* and *R. laciniatus* are certainly not one and the same, as Mr. Baker states. *R. quentlandicus* was sent to me many years ago by the late E. J. Lowe, and I understood that he had found it on the border of Wales, hence its name. The two plants are as unlike as possible. *T. Smith.*

RASPBERRIES AND BRAMBLES.—The first person, so far as I am aware, to suggest that *Rubus laciniatus* was a variety of *Rubus Selmeri*, which was then called *R. affinis* in England, was the late Lord de Tabley, poet, novelist, botanist, antiquarian, and author of a "Flora of Cheshire." I have found *R. laciniatus* in a wild state in two places in the English Lake district, one, a hedge near Grasmere and the other, less deeply lacinated, between Ulverstone and Swarthmore Hall, the residence of George Fox. Other wild British Brambles occur also occasionally with lacinated leaves, for instance *corylifolius* and *ulmifolius* (discolor, Bab.). In Vilmorin's catalogue there is mentioned a *Rubus affinis* var. *laciniatus*. In England *R. laciniatus* is commonly called Canadian Bramble or American Bramble, but all the recent American botanists refuse to admit it as an American plant. I ought to have included the Mahdi Bramble in my list. It is a hybrid, raised by Mr. Seden, between a wild English Bramble and *R. idæus*, so that it must take its place by the side of the Loganberry. It is mentioned in the "Hortus Veitchianus," p. 105, and is described, though without a name, in *Gardeners' Chronicle*, August 19, 1899, p. 167. I did not include *R. phœnicolasius* because it is not perfectly hardy. It is a very distinct Japanese Raspberry, of climbing habit, with densely glandular, bristly stems and sepals much longer than the very small petals. *J. G. Baker.*

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

JANUARY 22.—Present: Dr. M. T. Masters, F.R.S. (in the chair); Messrs. G. Massee, J. Douglas, J. Odell, E. A. Bowles, C. Hooper, F. J. Baker, W. C. Worsdell, G. S. Saunders, A. W. Sutton, and F. J. Chittenden (hon. sec.).

Mites in Amaryllis bulb.—Mr. SAUNDERS reported that he had examined the bulb sent to the last meeting from Folkestone, and had found that it was undoubtedly attacked by the bulb mite (*Rhizoglyphus echinopus*). He could see no reason why this mite should not infest Carnations, Tomatoes, Melons, Pelargoniums, Begonias, Cyclamen, Anemones, Lilies, and Cucumbers, which were also reported to be injured in a manner similar to that in the Amaryllis. "As to destroying the pest, I should suggest destroying all the soil the plants are growing in. Soaking the bulbs in hot water of a temperature of 125° Fahr. for about 10 minutes should kill the mites in the soil. I should recommend bisulphide of carbon, and it might be well to try vaporite; the latter is highly spoken of by some persons, but I do not know of any properly conducted experiments having been made with it."

Cucumbers "going off."—These, sent from Botley, were reported upon by Mr. SAUNDERS as follows: "I could find no signs of insects, worms, or mites in the Cucumbers, nor could I detect the mycelium of any fungus. The cellular tissue was much broken up in places, particularly near the nodes of the stems, a condition which looked very much like the work of eelworms, but I could not find any either in the stems or roots. I cannot suggest any reason for the plants 'going off.'"

Diseased Gooseberry shoots.—Mr. CHITTENDEN reported that he had examined the shoots of Gooseberry shown at the last meeting, and had found upon them a few perithecia of the common Gooseberry-mildew, but none of the American Gooseberry-mildew.

Cypripedium malformed.—Mr. SAUNDERS exhibited a curious flower of *Cypripedium*, in which, in addition to other malformations, a second flower was growing in the axil of one of the floral segments. Mr. WORSDELL will report more fully upon it at the next meeting.

Use of destructor refuse as manure.—Mr. F. J. BAKER said that he had found the refuse from a dust destructor in which condemned meat, infected clothing &c., had been burnt, very valuable as a manure. It contained a considerable amount of phosphates, and its effects were discernible after having been applied four years ago, the crops raised having been Vetches, Rye, Peas, and Barley. It was pointed out that the composition of the refuse probably varied very greatly from different districts, and its value could only be ascertained by analysis or by actual trial. The sample shown was in the form of a fine powder, and Mr. BAKER said he had found it very useful for mixing with potting soil.

Uncommon Conifera.—Dr. MASTERS showed specimens of leaves about 9 inches long of the Pine called in certain catalogues *Pinus Malleti*, a name which could not be found in any English list. The leaves enabled him, however, to identify the Pine as one of the numerous forms of *Pinus ponderosa*. He also showed six probably seedling varieties of *Torreya myristica* (= *T. californica*), which he had received from Messrs. CROUX, of Chatenay, where it is quite hardy, although it is scarcely so in England. The variations were principally in the form, direction, colour, and length of the leaves, and in the habit of the trees. He also exhibited a shoot of the true *Abies lasiocarpa* of Hooker, the species usually grown under that name being a form of *A. concolor*.

Roses dying.—Specimens of leaves and roots of Roses, and the soil in which they were growing, were received from Hoddesdon. The Roses lost their leaves very early, the Tea Roses especially suffering. The trouble was probably attributable to the somewhat heavy soil containing too small a percentage of organic matter, and the addition of farmyard manure was recommended.

Stocks diseased.—Stocks with leaves dying were received from Yateley. They were attacked by the slime fungus, *Plasmiodiophora brassicae*, the cause of the clubroot disease in Turnips, Cabbages, and all plants of the Cabbage family.

Mildew Apple shoots.—Apple shoots were received from Gloucestershire badly attacked by the mildew *Sphaerotheca mali*, a trouble that appears to be spreading (see *Journal R.H.S.*, vol. xxvii., p. 736, vol. xxviii., p. 2). Other diseased twigs from Falmouth were taken by Mr. MASSEE for further examination.

Apples spotted.—Mr. HOOPER showed several Cox's Orange Pippins spotted, which Mr. MASSEE took for further examination.

Gooseberry caterpillars.—Some soil from under Gooseberry bushes was received, and Mr. SAUNDERS undertook to examine it in order to discover whether any chrysalids of the Gooseberry saw-fly were present or not.

NATIONAL POTATO.

At the annual meeting of this society the name of Messrs. Sutton and Sons was used in a way which might lead to the inference that they were in sympathy with a proposal made by Mr. Cuthbertson (which received no support whatever) to wind up the society. Messrs. Sutton and Sons have expressed no view other than as concerns public exhibitions. They are not in favour of London shows. They regard the proposed experiments at Wye in 1907 as of real practical importance, and have offered a subscription to the society's funds with a view to supporting such experimental work. *W. H. Adsett, Hon. Secretary N. P. S.*

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

ANNUAL MEETING.

JANUARY 24.—The sixty-seventh annual general meeting of the supporters of this institution was held on Tuesday last at Simpson's, 101, Strand, London. Mr. Harry J. Veitch, chairman of committee, presided, and the small room in which the meeting was held (the Knights' room) was quite filled with gentlemen interested in the institution. When the minutes of the preceding meeting had been confirmed the secretary read the committee's Annual Report and Balance Sheet for 1906.

EXTRACTS FROM THE ANNUAL REPORT.

During the past year 17 pensioners have died, and one, whose circumstances have changed, has resigned the pension. Of the men who have passed away, four left widows, who, their cases having been investigated and found deserving and eligible, have been awarded the widow's allowance of £18 a year without election under the power conferred by Rule III., 18. Thus at the close of the year there were 14 vacancies and 208 pensioners on the funds. To this number the committee recommend the election of 18 additional pensioners from an approved list of 52 candidates at the annual meeting and election to be held this day, making a total of 224 persons in receipt of annuities for life—the largest number on the funds of the institution since its establishment—and 65 more than there were 10 years ago. It is gratifying to the committee to be able to help so large a number of worthy and deserving people, yet they deeply regret to be unable with their present income to render assistance to more candidates on the list.

The special funds, Victorian Era Fund and the Good Samaritan Fund, still prove of incalculable benefit. During the year £161 has been distributed from the former fund to seventeen unsuccessful candidates who were formerly subscribers to the institution, and in the same period a sum of £108 15s. was given from the latter fund as temporary relief to applicants in urgent distress and need. The grateful letters from the recipients show how much this timely help was required and how keenly it was appreciated. In addition to the amounts mentioned above a further sum of £50 was distributed among the unsuccessful candidates, being a special gift from that well-known friend and generous supporter of the charity for so many years, Mr. N. N. Sherwood, Esq., V.M.H. (trustee), who is most gratefully thanked by the committee and beneficiaries alike for his kindness.

It is with much pleasure the committee have to report that the 67th anniversary festival dinner, held in June last at the Hotel Métropole, was one of the most successful in the history of the institution. They take this opportunity of acknowledging their great indebtedness to the Right Hon. Lord Balfour of Burleigh, K.T., who so kindly presided on that occasion.

They also desire to tender sincere thanks to those gentlemen who so kindly acted as stewards, especially to P. Murray Thomson, Esq., S.S.C. (Royal Caledonian Horticultural Society), David W. Thomson, Esq., and W. H. Massie, Esq., whose lists of contributions exceeded in amount any sum previously remitted from Scotland to be added to the chairman's list. The committee again gladly recognise the self-denying labours of the hon. treasurers and hon. secretaries of the several auxiliaries.

In the past year, by the kind permission of the Right Hon. Mary Countess of Ilchester, the beautiful gardens of Holland House were allowed to be opened to the public on the occasion of the great exhibition of the Royal Horticultural Society, a charge being made for admission, and two-thirds of the proceeds thus obtained were allocated to the funds of this institution. They also sincerely acknowledge similar kindnesses from Earl Beauchamp, Madresfield Court, and C. W. Dyson Perrins, Esq., Davenham Bank.

It is with feelings of deep regret that the committee have to record the decease in the past year of many valued supporters, among whom they would mention their esteemed friends and colleagues, Mr. Harry Turner, V.M.H., and Mr. George Norman, V.M.H., also Mr. H. E. Milner, a generous subscriber for many years, and Mrs. Lewis-Hill, who evinced her interest by most kindly remembering the charity in her will. The Hon. Walter Rothschild, M.P., has kindly undertaken to preside at the sixty-eighth anniversary festival dinner in aid of the funds, at the Whitehall Rooms of the Hotel Métropole, on Wednesday, June 26, 1907.

After the report had been read, its adoption was moved by Dr. M. T. Masters, F.R.S., and, on Mr. Iceton seconding it, the report was accepted unanimously. On the proposition of Mr. George Monro, seconded by Mr. Arthur Sutton, Mr. Harry J. Veitch was re-elected treasurer by acclamation. Mr. H. J. Veitch proposed the re-election of Mr. G. J. Ingram as secretary, and this was carried without dissent. The retiring members of the committee were re-elected, and Messrs. A. W. Paul and C. R. Fielder were elected to fill the vacancies

caused by the decease of Messrs. George Norman and Harry Turner. The auditors and arbitrators were re-elected.

Messrs. B. J. Monro and Percy G. White were thereupon elected scrutineers of the ballot, and the meeting was adjourned till the result of the voting had been ascertained.

SUCCESSFUL CANDIDATES.

On the resumption of the meeting the chairman declared the following 18 candidates duly elected:—

	Votes.		Votes.
Perkins, George	8,487	Gooderham, George	2,696
Hollingworth, Eleanor	8,186	Murray, George	2,639
Lowe, Richard	8,015	Sedgley, Jas. W.	2,618
Cole, Sarah	2,988	Capstick, Geo.	2,565
Selway, John	2,924	Buby, Thos. B.	2,564
Campbell, W. S.	2,858	Peacock, Chas.	2,262
Young, William	2,858	Wilder, Ann J.	2,265
Dean, Mary A.	2,774	Alley, Chas. H.	2,218
Dawes, George	2,768	Port, James	2,116

Mr. Harry J. Veitch then remarked that the rules allowed the committee to elect not more than two pensioners beyond the number elected by the subscribers, and the committee proposed on this occasion (assuming that the subscribers present assented to the proposal) to elect George Melome, aged 75 years, who was the highest but one on the list of unsuccessful candidates, had been a life member of the institution for 18 years, and had applied for relief five times; also Mary Ann Hodges, aged 75 years, who had made application for relief on four previous occasions. These proposals were carried by acclamation.

Mr. Veitch also reported that Mr. N. N. Sherwood, writing on the 22nd inst., had sent a cheque for £20, and wished the treasurer and secretary to divide the sum between four of the unsuccessful candidates. Mr. Arthur W. Sutton (Reading) had also that day handed Mr. Veitch a cheque for £20, in order to provide one year's pension for still another unsuccessful incapacitated candidate, to be afterwards selected. Thus there were altogether 21 new pensioners elected.

THE ANNUAL FRIENDLY SUPPER.

After the business proceedings of the day were completed, the committee and a few friends supped together at Simpson's, Mr. Ed. White presiding. On proposing the toast of the "Gardeners' Royal Benevolent Institution," Mr. White spoke of the increased love there was for gardening, as shown by the number of amateurs who follow it as a source of interest or recreation. In connection with this subject, he drew a parallel between gardening and influenza. "Most people get it sooner or later," "It can never again be got quite out of the system," "It shows itself in many different forms," "The attacked are always ready to talk of their own experience." But Mr. White, passing on to the consideration of the future of the institution, said that many of those present were called upon at different times to advise new amateur enthusiasts in gardening. He thought they should make it a rule to append to the more technical advice the suggestion that the client should support the Gardeners' Royal Benevolent Institution. After expressing some disapproval of a State scheme of old age pensions, Mr. White said that in the future their institution would be made more equal to the demands for help by the improved education of gardeners. He did not wish to be misunderstood, as he knew perfectly well that many gardeners were all that could be desired. At the same time the mass, especially those employed in the smaller gardens, needed to be lifted in the social scale, and to be better educated. In this connection he said that it was absurd that gardening enthusiasts should employ gardeners at lower wages than they would give to unskilled workmen. At present anybody, even some who might be worthless and undeserving, could call themselves gardeners. He (Mr. White) read a letter in which a gentleman asked him to procure a fresh gardener, for the other man had actually "sent the celery tops to the kitchen and left the crowns in the soil, and had staked the tall Yews in such a fashion that the Yews appeared to be supporting the stakes." This extreme case was cited to show that gardening should first be rid of such impostors, and that those fully qualified should meet with better remuneration than they got at present.

Mr. Harry J. Veitch replied and said he was pleased to believe that the man mentioned by Mr. White was by no means typical of the body of

gardeners. He was very pleased that the institution was able to do what it is doing, but he would like to find the committee in such a position that they could elect all the candidates for help.

Mr. Geo. Paul proposed the toast of "The Committee," to which Mr. Geo. Monro responded, drawing especial attention to the number of unsigned voting papers (162) which had been received that day, all those votes were lost, and some candidates may have been unsuccessful in consequence. Other toasts included a compliment to the secretary, which was suitably acknowledged by Mr. G. J. Ingram.

LINNEAN SOCIETY.

JANUARY 17.—Prof. W. A. Herdman, F.R.S., President, in the chair.

The General Secretary drew attention to the copy by Jean Haagen of the portrait of Carl von Linné, by J. H. Scheffel, dated 1739, now preserved in the Linnean Museum at Hammarby, which had been presented to the Society by the University of Upsala. Mr. Carruthers and Dr. Murie having spoken, a special vote of thanks to the University for this most acceptable gift was voted unanimously.

The first paper, by Mr. W. Botting Hemsley, F.R.S., F.L.S., on "Platanthera chlorantha, Cuscut, var. tricarata," was, in the absence of the author, read by Dr. Stapf. The specimen had been found at Pax, Sherborne, Dorset, by Miss D. R. Wilson, who sent it to Kew; the ten flowers on the spike were modified as described, the paired sepals were spurred, and the lip was uppermost, that is, the usual twist of the ovary was absent.

The second paper was by the late Mr. Charles Baron Clarke, F.R.S., F.L.S., entitled "Acanthaceae of insular Malaya," and was introduced by Dr. Stapf, in the absence of Mr. J. S. Gamble, who was unable to be present. This paper was complementary to a similar one, drawn up for the "Materials for a Flora of the Malay Peninsula," now in course of issue by Sir George King and Mr. Gamble.

The General Secretary exhibited some lantern slides from Dr. Lindau's drawings to show the diversity of pollen in this family, and the scheme of naming adopted.

Obituary.

SIR MICHAEL FOSTER.—It is with the greatest regret that we are called on to announce the sudden death of this distinguished physiologist, eminent horticulturist, and, may we add, personal friend. He was present at the meeting of the British Science Guild at the Mansion House

THE LATE PROFESSOR SIR MICHAEL FOSTER, F.R.S.

on Monday last, but died on the following day. He was born in 1836 at Huntingdon, the son of a leading medical practitioner in that town. His medical education was pursued at University College, London, and after practising as a medical man for a few years in Huntingdon, he returned to London as Professor of Physiology at

the college at which he had been educated under Sharpey and others. From thence he proceeded to Cambridge, where he ultimately became Professor of Physiology, got round him a band of earnest students, and founded a "school," if we may so call it, which has exercised a profound influence in the promotion of science both in and out of the University. It is to his influence as a teacher and a leader, and for his many public services, rather than as an original investigator, that he will be longest remembered. What Cambridge now is as a progressive University is in no slight degree owing to the quiet, persistent energy of Michael Foster. He was President of the British Association at the Dover meeting in 1899, joint secretary of the Royal Society from 1881 to 1903, and M.P. for the University of London from 1900-1906. To horticulturists he was well known for his love of gar-

JOSEPH BROOME.—We regret to have to record the death of this enthusiastic horticulturist, which took place, in his 82nd year, at his residence, Sunny Hill, Llandudno, on January 25.

Mr. Broome was extensively engaged in business in Manchester, and for the greater part of his life, was the leading spirit in horticulture in that district, and for many years Treasurer of the Manchester Botanical and Horticultural Society, whose shows at Old Trafford in those days were famous. For many years he resided at Wood Lawn, Didsbury, Manchester, and grew Orchids extremely well, some of his specimens being figured in the *Gardeners' Chronicle*. Especially fine was a plant of *Vanda teres*, with 250 blooms.

Of late years Mr. Broome has resided at Sunny Hill, Llandudno, where he made his garden and Orchid houses his chief pleasure, and their

of the pond, which is the lowest point, pipes have been laid underneath the concrete to a dry well, for the purpose of emptying the pond at any time. I should be glad to know as to the best valve to use for the top of these pipes—one that could be easily manipulated under 2 feet 6 inches of water. *Aquatic.*

MICE ATTACKING VINES: H. C. would like to learn if gardeners find it a common thing for mice to eat the bark of vines. On one vine he knows they have eaten the bark for a foot up from the ground quite round the rod. Will it be possible for that vine to continue to live and yield a crop of fruit? They have eaten several vine stems half-round. What is the best thing to do? The mice are similar to a dormouse, but the colour is that of a house mouse. They have short tails. [It should be easy to catch these creatures in traps. In the meantime protect the

FIG. 36.—VIEW OF THE RESIDENCE OF THE LATE SIR MICHAEL FOSTER, F.R.S., SHELFORD, NEAR CAMBRIDGE.

dening, and his numerous writings on the genus *Iris*, published mostly in our columns and in the *Journal* of the R.H.S. He will also be gratefully remembered as one of those who at the darkest period of the fortunes of the R.H.S. gave his services, and in no slight degree contributed to pull the society out of the slough into which it had fallen. He was a frequent contributor to our columns and to those of the *Garden*. Our own association with him began under sad circumstances, when, owing to the death of his first wife, he was unable to continue his course of lectures at the Royal Institution, and the present writer was hastily called on to complete the course. It was many years afterwards that we were thrown into intimate contact with him at the R.H.S., as above mentioned. Sir Michael leaves a widow, a daughter, and one son practising medicine in the Riviera.

beauties have frequently been illustrated and described in these pages.

Although engaged closely in his commercial enterprises, Mr. Broome spent a great part of his time in improving the institutions of Manchester and other districts in which he was interested, and especially those which benefited the working classes. He took a leading part in the establishment of the Manchester Warehousemen and Clerks' Provident Association in 1854, and was always active in educational projects. In 1891 he was elected High Sheriff of Carnarvonshire. He was a never-failing contributor to charitable institutions.

ENQUIRIES AND REPLIES.

VALVE FOR USE IN POND.—I am making a pond, the bottom being concrete. From the centre

vine stems by enclosing them in very close-meshed wire netting. Unless we see exactly how deeply the mice have eaten the bark and cortex away, we cannot say whether the vine may live or not, but it will certainly suffer.—ED.]

ANSWERS TO CORRESPONDENTS.

* * * The Editor will be glad to receive, for consideration, large photographs of horticultural subjects, suitable for forming Supplementary Illustrations to this Journal.

APPLE TREE INJURED: *Mac.* The larvæ of the Leopard moth, *Zeuzera æsculi*.

ARAUCARIAS: *E. A. H.* The cones you send are the male catkins which are generally borne on distinct trees from the female cones.

CUBA: Enquirer. The correct address of the Director of the Agricultural Station of Cuba is Senr. C. F. Baker, Jefe del Departamento de Botanica, Santiago de las Vegas. The Estacion Agronomica is situated in that place, which is a few miles distant from Havana. All letters relating to exchange of plants, &c., should be addressed as above. As there are many towns of the same name it is necessary to write Santiago de las Vegas.

DEODAR: W. O. We cannot tell you how long the Deodar is likely to live in this country. It was introduced in 1881, and although it does not grow rapidly in all places, we have not seen anything like senile decay in it yet.

GARDENING EMPLOYMENT IN THE UNITED STATES: C. E. S. We have submitted your questions to a gardener who has recently returned from a private garden in the United States, who replies as follows: "The wages for under and single-handed gardeners are from \$35 to \$50 a month; head gardeners are paid \$50 to \$100 per month, with house and coal. The demand for labour is better than in the nineties, but for under-gardeners England is still the best. Situations in private places are hard to obtain, and an establishment employing five or six men is considered a large one. A directory of every city can be seen in any drug store. The duties of gardeners are somewhat different to those in this country. Greenhouses are all heated with steam-burning cobbles. Violet frames and similar structures have a foot or more of matting material p'aced round the frame to guard against damage by cold snaps. Plants in greenhouses are easier cultivated, and about May the syringe is discarded for the hose. Vegetables, including Sweet Corn, Tomatos, Cantaloupe, Melons, Sweet Potatoes, Capsicums, &c., are grown in the open. Peaches are trained in a bush form, and during their first year of planting will attain a height of 3 feet from a stone. Twenty feet is a common length for a vine to attain on a building in summer. An arbor of vines is found in the majority of kitchen gardens. If you decide to go, buy no special clothes, but take what you happen to have. Leave your hob-nailed boots behind, you will find they have no use there, being too cumbrous. Forget what nationality you are on landing, for you will have to compete against persons of nine or ten nationalities. If you have no friends, you must have £6 in your pocket on landing. Should you have accepted an engagement before landing you must remember there is a law in the United States which forbids this, the penalty being deportation to the place of embarkation if you are found out. The right time to arrive is the third week in March. On arriving the first thing to do is to place your name on every register you can, whether of florist, seedsman or nurseryman."

GETTING-OUT OF BEECH TREE-STUMPS: J. G. P. C. The chemical you have heard of is probably strong carbolic acid, which, if poured on the roots occasionally, would cause them to decay, but the process would, we fear, be very slow.

GREENHOUSE TANK: Ashtonian. If you cannot localise the leak, your best plan will be to "float" the walls and bottom with a coating of cement. See that it is thoroughly dry before you admit the water.

HELLEBORE BLOTCH: Mrs. D. The leaves of Christmas Rose are affected by a fungus, *Conothyrium Hellebori* (Cke. and Mass.), not uncommon in this country, but as yet apparently unknown abroad. The blotches are brown, more or less round, marked in concentric rings by the pustules which enclose the small brown spores or conidia. Pick off and burn all diseased leaves. Syringe the plants with Bordeaux mixture. See *Fungoid Pests of Cultivated Plants*, p. 11, plate 1, fig. 3.

MOVING HYACINTHS FROM BOXES: S. F. D. H. If the work is done very carefully, and warm soil is used, it will be quite safe to pot the Hyacinths, and the sooner it is done the better. Do not use any artificial manure, but a little well-decayed stable manure may be added to the soil, and liquid manure made from soot and cow-dung can be applied when the flower stems are in a well-advanced condition. Hyacinths and other bulbs have often been injured through the too liberal use of artificial manures.

NAMES OF FLOWERS, FRUITS AND PLANTS.—We are anxious to oblige correspondents as far as we consistently can, but they must bear in mind that it is no part of our duty to our subscribers to name either flowers or fruits. Such work entails considerable outlay, both of time and money, and cannot be allowed to disorganise the preparations for the weekly issue, or to encroach upon time required for the conduct of the paper. Correspondents should never send more than six plants or fruits at one time: they should be very careful to pack and label them properly, to give every information as to the county the fruits are grown in, and to send ripe, or nearly ripe, specimens which show the character of the variety. By neglecting these precautions correspondents add greatly to our labour, and run the risk of delay and incorrect determinations. *Correspondents not answered in one issue are requested to be so good as to consult the following numbers.* FRUITS: J. R. B. 1, Calville St. Sauveur; 2, Gogar Pippin; 3, Duke of Devonshire; 4, Forge. —E. B. Northern Greening.—J. P. R. Devonshire Buckland.

PLANTS: J. H. B. 1 and 12, *Adiantum formosum*; 2, *Polypodium pustulatum*; 3, *Aspidium decompositum*; 4 and 11, *Davallia hirta cristata*; 5, *Lomaria gibba*; 6, *Polystichum angulare*; 7, *Davallia polyantha*; 8, *Davallia fijiensis plumosa*; 9, *Nephrolepis pectinata*; 10, *Nephrolepis tuberosa*; 13, *Davallia fijiensis major*.—A. F., *Midlothian*. 1, *Cypripedium Lathamianum*; 2, *Cypripedium Hiers* (*Chamberlainianum* × *Lawrenceanum*); 3 and 4, *Cypripedium Leeanum*.—C. E. F., *Lycaste costata*.—T. N. 1 and 2, probably *Phoenix dactylifera*; 3, *Chamaerops* sp., perhaps *C. humilis*; 4, not *Vanda* but *Angracum sesquipedale*; 5, the young state of *Cupressus pisifera*, the *Retinospora squarrosa* of gardens; 6, *Chamaerops Fortunei* probably.—J. W. 1 and 3, *Cupressus nootkensis*, commonly called *Thuopsis borealis*; 2, 4 and 5, *Cupressus Lawsoniana*.

FIG. 37.—THE COCKCHAFER, OR MAY BUG, AND LARVA.

GRUBS EATING ROSE ROOTS: A. S. The grubs you send are the larval stage of the cockchafer, or may bug, fig. 37. The best plan to rid the land of them is to stir up the soil and allow poultry, especially ducks, to devour them. Encourage wild insectivorous birds, such as starlings and rooks, to feed on them.

NATURAL SELECTION: X. As the article in question was not inserted in the *Chronicle*, and so much has already been said relating to it, we cannot, especially in the crowded state of our columns, give further space to it. The subject is to be brought forward again at the R.H.S., when you may have an opportunity of again making known your views.

ORCHARD MAKING: M. W. The articles were published in our issues for January 20, February 17, and March 10, 1906. Copies can be had from our publishing department.

PALMS: Lexden. It will be better to defer the repotting until March or April, because the roots will then be able the more quickly to re-establish themselves.

PLANTING OF COLCHICUMS: B. L. The depth at which corms of Colchicums should be planted depends to a great extent on the nature of the soil. If this is of a heavy nature a covering of

about an inch will be sufficient. In sandy or light soil they may be planted at a depth of 3 inches or even more than this below the surface. The principal conditions they require are to be planted where the corms will get thoroughly ripened during the summer months, and yet get plenty of moisture during the growing season. When established and doing well it is advisable to leave them alone, for they do not like to be disturbed very often. Clumps of several corms growing together always produce plenty of flowers, whereas if taken up and separated and planted singly, it takes two or three years before they again commence to flower freely.

PUNNET OF SEAKALE: T. W. C. An ordinary punnet of Seakale at Covent Garden Market should weigh about 2 lbs.; some may be rather a little over that weight. We have also seen Seakale put up in 1 lb. punnets, for sending to certain provincial markets.

RHUBARB FOR USE AT CHRISTMAS: F. J. G. On Tuesday, November 4, 1902, the Royal Horticultural Society granted an Award of Merit to both Messrs. Sutton & Sons, of Reading, and to Messrs. Jas. Veitch & Sons, Chelsea, for a variety of Rhubarb known as Christmas. It was stated that it made its roots in the summer and developed its leaves in the autumn. The petioles shown at the November meeting were grown without protection, but in hard weather tubs or boxes should be placed over the crowns. This variety can easily be grown so as to be ready for use at Christmas. Daw's Champion is another excellent variety for early forcing; it received an Award of Merit from the R.H.S. on February 13, 1900, as a forcing variety, and later a First Class Certificate from the same society for earliness and general excellence. After being forced, the crowns should be divided and planted in the open, being allowed to remain undisturbed for three years, when they will be ready for forcing again. A good plan is to plant three rows, and to force the plants of one row each year, replanting a fresh one to take its place, which will thus be ready for lifting the third year following.

TULIP AND DAFFODIL BULBS: F. J. G. These should not be forced a second time, but you might plant them in some suitable place in the pleasure-garden, where the bulbs may have an opportunity of regaining vigour and size.

VIOLETS DISFAS: C. S. and J. R. F. The plants are attacked with a fungus disease. Burn all the affected stock, and do not plant violets on the same spot for several seasons. If possible, obtain new plants from a distance. Thoroughly cleanse the frames in which they were forced with carbolic acid and warm water.

WAGES DURING ILLNESS: Head Gardener. The head gardener being considered by the law to be a "menial" or household servant, your employer is not within his rights in withholding from you part of your wages for six days' illness in eight years, during which six days you were unable to discharge your duties. In any case, such treatment is as harsh as it is unusual. Write to the Executive of the British Gardeners' Association. The Secretary's address is Talbot Villa, Talbot Road, Isleworth.

WEED IN LAWN: C. W. The specimen was shrivelled and no flowers were present, but we believe it is one of the chickweeds, probably *Cerastium vulgatum*. Give the lawn a dressing of sulphate of ammonia. In the series of experiments on pasture land conducted at Rothamsted, it was found that ammoniacal manures were detrimental to the development of this weed.

WORKMEN'S COMPENSATION ACTS: E. J. V. Certainly the employees in nurseries and market gardens have the protection afforded by these Acts.

COMMUNICATIONS RECEIVED.—H. J. H. (Is. for the R.G.O.F.).—Herbert Hoare, H. Maw, and D. Malton, your letters have been forwarded to the president of the Société Française d'Hort. de Londres.—J. T. COBNUTS AND FILBERTS.

TO be successful in nut-culture, the trees or bushes should be planted in a situation where the atmosphere is usually pretty dry and the soil perfectly free from stagnant moisture. Land which is freely intermixed with stones, having only sufficient soil to answer the purpose of a rooting medium, or a rocky limestone, or a soil freely intermixed with shaly fragments, such as the Kentish rag-stone, will all suit a nut crop perfectly. Rich or damp ground excites the trees into making too much growth, and they are then seldom very fruitful. Some land which is useless for ordinary fruit-culture is capable of yielding good nuts. Ground which has not been previously dug up should be well stirred and either trenched or bastard trenched, and if of poor quality a little manure intermixed with the soil would induce the trees to make a good start. A distance of 10 to 14 feet between each tree is necessary for the trees to develop properly, but there are certain dwarf-growing varieties that might be planted closer together.

Young trees having a clean, smooth stem about 18 inches in length are the best, and those raised from layers preferable. These are easily obtained by layering two-year-old shoots and making a parallel incision on the under side of the shoot, where it is in contact with the soil, firmly fastening it down with a strong peg, and covering the operated part to a depth of 6 inches with soil. Generally speaking, layering is performed in March, but it should preferably be done in autumn. The young trees can then be detached from the parent plant in from 10 to 12 months after the operation; they should be carefully examined in order to remove all eyes liable to produce suckers.

Suckers are planted in place of layers by some growers, but trees so raised are predisposed to perpetuate themselves by this means.

In the obtaining of trees, much time is saved by purchasing them from a nurseryman who has given them early attention in pruning. Well-rooted trees, with evenly-distributed branches, soon establish themselves and commence bearing. Certain varieties are more precocious than others, while those kinds

FIG. 38.—FILBERT SHOOT PROPERLY PRUNED, WITH SHORT SPURS BEARING THE FEMALE FLOWERS.

which fail to crop freely, owing to their greater vigour, may be grafted on a weaker stock in order to induce fruitfulness.

Far heavier crops of nuts would be produced than are now general if earlier and annual attention were given to the work of pruning. In many cases the trees have never had a branch shortened, or one removed since

FIG. 39.—THE NUT WEEVIL: *BALANINUS NUCUM*.

they were planted. It is quite as necessary to prune and thin nut bushes as other fruit trees. Nuts respond well to good treatment, and will yield a return from ground that some would describe as worthless.

Pruning and training should be commenced when the trees are young. In order to regulate the branches the best method is to

place a wooden hoop inside the branches, carefully pressing the branches outwards to the desired position, and securing them to the hoop. Six shoots will form the foundation of a good tree. Any vigorous shoots should be shortened to equalise the flow of sap. The small "spray growths" and short twigs and spurs are the fruitful portions, consequently these should be only shortened or left untouched. All strong-growing unfruitful wood must be entirely removed, and those shoots which are inclined to grow towards the centre of the tree. Suckers must be vigorously removed.

Old trees may be rejuvenated by severely shortening the branches down to a point where there is a promising shoot. By the exercise of a little skill, such old trees may be induced to form well-balanced heads again, but it would be much better to keep them shapely and fruitful from the commencement, and always within reach of the cultivator.

In the course of a few weeks the distribution of the pollen from the male catkins will be taking place, and that is the best time for carrying out the pruning. A considerable number of these male catkins may be cut away, and placed amongst other trees where there is a deficiency, so as to ensure the pollination of the flowers. The male catkins of the Hazel will also assist in obtaining a good "set" of nuts.

Manuring may be practised with good results when the trees have attained to their full bearing-size, but a little care should be used in its application. Farmyard manure is best, although the refuse from tan-yards will also produce excellent results. It should be applied early in the autumn, and when the leaves have fallen, the whole being lightly dug into the ground; one or two applications of liquid manure, after the nuts are set, will aid much in increasing their size and quality.

The nut weevil (see fig. 39) is a destructive insect enemy. The female makes her appearance in April and May, visiting the individual nuts, depositing an egg in each. The grub is hatched out in 10 days, and commences feeding on the kernel, which it leaves when fully developed, by perforating a hole through the shell. The grub then buries itself in the ground, changes later into a pupa, from which the weevil emerges to ascend the trees again, thereby forming the cycle of life.

The distinction between the Cobnut and Filbert is that the husk of the Cobnut is shorter than the nut, and that of the Filbert longer than the nut.

Varieties.—Perhaps the most prolific and certain bearer is the Kentish Cob. Prolific Dwarf Cob is of low growth and suitable for small gardens. This variety produces a profusion of male catkins. Merveille de Bollwyler is a strong grower, and a good cropper, the nuts being large. The Red Filbert is the best flavoured of all nuts, but the tree is not a satisfactory cropper. Cosford is a Filbert of good flavour, having a very thin shell; this kind is well suited to plant amongst those which produce catkins sparsely, it being a variety which produces them with great freedom. Other varieties worth growing are Atlas and Bergeri Cobs, Early Prolific, Duke of Edinburgh, and Kentish Filberts. W. H. Clarke, Aston Rowant, Oxon.

ASPARAGUS FALCATUS.

Of the numerous species of *Asparagus* cultivated at Kew, the subject of the illustration at fig. 40 is certainly the finest. It is growing in the great Temperate House near the foot of the spiral staircase at the north end of the building, where it has assumed immense proportions, covering in a dense thicket two large columns to a height of 30 feet and also partly clothing the spiral staircase and ascending along light strings right up to the roof. When in bloom in August and September of last year, the whole plant was covered with flowers, similar to the single growth depicted in the illustration, while the powerful perfume emitted by the flowers pervaded the whole house.

The plant is of twining habit, the growths persisting for several years, and retaining their leaves for a like period. It is usual for the plant to send up a crop of strong succulent growths from the base early in spring, which often reach a length of 50 or 60 feet in a single season. These become hard and woody as they ripen, and the short reflexed "leaves" harden and become changed into strong hooks, and so assist the plant in its climbing habit and also serve as a means of protection. Numerous lateral growths are later on produced, from which the so-called leaves (cladodes) and flowers are produced. The cladodes are from 2 to 4 inches long and about $\frac{1}{2}$ inch broad, falcate, and of a light green colour. The flowers are pure white, $\frac{1}{2}$ inch in diameter, with bright red anthers, and are disposed in loose racemes, which are from 2 to 5 inches in length and 1 inch in breadth. The fruit is a globose berry, and dull brown in colour. The plant is a native of tropical Asia and Africa, and was introduced into cultivation by Mr. T. Cooper (of succulent plant fame) when collecting plants in South Africa. A fit companion to the above-named species, and one which bears the name of its discoverer, is *A. Cooperi*, a large specimen of which is growing in near proximity to *A. falcatus*. It is of more slender habit, but many of the growths reach to a height of 30 to 40 feet. Other species worth mentioning, which are used for clothing pillars, &c., at Kew, are:—*A. aethiopicus*, *A. medeoloides*, *A. myriocladus*, *A. retrofractus* var. *arboreus*, *A. racemosus*, *A. plumosus*, *A. africanus*, and *A. Duchesnei*, a new comer from the Congo Free State, and one of the finest species in cultivation. For cultivation in baskets, I know of nothing finer than *A. Sprengeri*, while amongst others specially suitable for such cultivation are:—*A. crispus*, *A. declivatus*, *A. sarmentosus*, and *A. umbellatus*. C. P. Raffill.

ORCHID NOTES AND GLEANINGS.

"DICTIONNAIRE ICONOGRAPHIQUE DES ORCHIDEES."

THE first issue of this work for the year 1907 gives illustrations and descriptive notes of the following 13 Orchids:—

Cattleya Fabia, var. *Marie de Wavrin*.—A charming hybrid raised by M. Peeters, of Brussels, between *C. labiata alba* and *C. Dowiana aurea*, and for which an Award of Merit was given at the Royal Horticultural Society, October 27, 1903. Varieties of the same hybrid are in the collection of the Marquis de Wavrin, and the one figured in that of M. Lambeau, president of the Floral Committee of Brussels. Flowers white, with a marbling of rose colour in the centre and on the margin of the lip, which has an orange-coloured base.

Cattleya Warszewiczii Mme. Melanie Beyrodt. —A fine pure white variety, with purple front to the lip, first shown by Herr Otto Beyrodt, of Marienfelde, Berlin, at Holland House, July 12, 1904, when it gained a First-Class Certificate. The plant figured flowered with M. Lambeau.

Calogyns miniata Lindley.—The *Chelonanthus miniata* of Blume, and a very rare Javan species of small growth bearing racemes of five to seven bright red flowers. Figured from the collection of the Baron von Furstenberg.

Epidendrum aurantiacum.—The well-known species from Guatemala, with the growth of *Cattleya Skinneri* and orange-scarlet flowers.

Lalia-Cattleya Berthe Fournier, var. *obscurapurpurea* (L.-C. elegans $\times$ C. Dowiana aurea). —Flowers of an intense purplish-red, with a lilac shade in parts of the petals. Bloomed by M. F. Lambeau. The original L.-C. Berthe Fournier, recorded as having been raised between L.-C. elegans and C. aurea, was obtained between L.-C. Schilleriana and C. aurea, by the

FIG. 40.—ASPARAGUS FALCATUS IN FLOWER. [Photo by C. P. Raffill.]

evidence of the flowers, and by the fact that that hybrid which is commonly imported with the darker-coloured L.-C. elegans often goes under that name. Major G. L. Holford, of Westonbirt, Tetbury, however, raised the properly authenticated cross between L.-C. elegans and C. Dowiana aurea, and received awards for several of his best varieties, and at the same time proved the error in the original Continental form. The variety figured resembles Major Holford's.

Lælio-Cattleya Fräulein Lotte Abcken.—A very showy hybrid, with purplish-rose sepals and petals, the bases of which are white. Lip ruby-purple, with an orange tint at the base. The cross (L.-C. elegans × C. labiata) has been previously named L.-C. Schutzeriana, L.-C. Wilhelmina, and L.-C. Capt. Percy Scott, and with regard to the last named, the same remarks as to parentage given under L.-C. Berthe Fournier applies, for it is evident the L.-C. Schilleriana was the form used, and not L.-C. elegans.

Ornithidium coccineum.—A pretty species from Central America, with red flowers.

Odontoglossum Boddartianum, var. *arachnoides*.—A slender species of the O. constrictum class, and probably nearest to O. aspidorhinum Lehm. Sepals and petals yellow, striped with brown; lip white, with purple spots.

Odontoglossum Thompsonianum, var. *de M. Oscar Fanyau* (crispum × Edwardii).—First shown by W. Thompson, Esq., Walton Grange, Stone, at the Royal Horticultural Society, April 25, 1905, when it obtained a First-Class Certificate. The present variety bloomed in three years from the sowing of the seed, it is said, in the collection of M. Fanyau, Hellemes, near Lille. The original variety had the sepals and petals almost entirely of a claret colour; the variety figured has the outer third of the segments of a light rose colour.

Renanthera Imschootiana.—A very showy species from Burma, with blood-red flowers. A full-page illustration of it was given in the *Gardeners' Chronicle*, January 15, 1898, p. 41.

Renanthera Storiei.—Allied to R. coccinea, and with flowers of a dark red colour. Native of the Philippines.

Selenipedium torconense (Pearcei × Lemoinierianum).—Raised and flowered by M. Lemoinier, of Lille. A graceful hybrid, with whitish flowers marked with brown, yellow, and purple, the long twisted petals plainly indicating S. Pearcei.

Sophro-Lalia Psyche (L. cinnabarina × Sophronitis grandiflora).—Raised by Messrs. Charlesworth & Co., Heaton, Bradford. Flowers reddish-scarlet.

HARDY FLOWER GARDEN.

SENECIO PULCHER.

In its season of flowering, in the late summer months, this remarkable Groundsel is well nigh unique, and as such deserves to be liberally and specially cultivated. This species, quite unlike many of its congeners, is a shy seeder, and only rarely produces seeds in this country. Added to this the plant does not lend itself to division so freely as do some plants, hence there is the greater need for the adoption of special means for its propagation, namely, from root cuttings. Root cuttings may be obtained from any old plant, and a single plant will yield 50 or 100 of suitable root-pieces, which should be about an inch in length. It is necessary when cutting up the roots into short lengths to see that they are laid so that they can be planted the right way up. When a sufficient number of root portions are ready a well-drained pot 5 inches in diameter should be filled to within an inch of the top with sandy soil; the root-pieces can then be arranged nearly close together around the interior of the pot and the central portion filled with soil. Water thoroughly and place the cuttings in a warm greenhouse. In about five weeks

from their insertion the apex of each cutting will be showing numerous growths, and a little later the plants may be potted singly and otherwise treated as separate plants requiring care and attention. No other method produces such fine flowering rosettes as that above described. E. H. Jenkins.

THE COUNTRY GARDEN.

BORDER PLANTING.

In my previous article I spoke of the uninteresting monotony of many of our English gardens, occasioned by the repetition of the varieties of plants seen in them. I want now to touch on another kind of monotony that makes itself apparent in too many gardens. I mean the monotony that arises in finding the same varieties of plants in all sorts of positions in the same garden. We must all have noticed it from time to time, and it is an error that can very easily be rectified when once it is realised.

I cannot agree with those purists who declare we should have but one group of a particular plant in a border. I would say, repeat it there, as often as you wish; let it, if you will, become a striking feature, whatever it may be, in its own border—even in two or three borders if it be a very large garden. But be content with that. Do not introduce it here, there, and everywhere, all over the garden. I have seen the beautiful white *Campanula persicifolia* (the cup-and-saucer variety) finding a place in every border and mixed bed in an old garden, used until one longed to see something change place with it to relieve the unrelieved sameness of idea. Ah, and I have seen it often and often with different plants to a less extent. To use plants in this fashion is to take away all distinction and character. Again, I would say, it is most unwise to lift and divide the plants of a border, and with the surplus specimens thereupon to plant some other border. It is often done, and the result is, that the second is a counterpart of the first. What ought to be done under these conditions is to allot certain varieties to one border, and use them freely, and different ones for the other; thus I would use up all the *Phlox decussata*, say, in one border, and not allow it to appear at all in the other, and so on. A far more characteristic and distinctive garden will be the result.

A few years ago, writers on gardening topics waxed eloquent on various colour-schemes. There was to be a gradual leading up to the different colours—thus, orange was to be placed in juxtaposition to red, and we approached blue through yellow. But, if this idea were largely adopted, and it came to be a kind of rule of thumb, another, and quite artificial cause of monotony would exist. There are colours difficult to place, and of course in planting any border we shall have to bear in mind this question of colour-harmony, or pleasing contrast. But Nature gives us a wide latitude in this matter, and with a little care no crude clashing effect will be produced.

I look upon a bright, vivid rose colour as one of the most valuable to use generously, especially for summer effect. There is a translucency and gaiety about it that the thicker and more solid red does not yield. It is a colour I would have run riot during August through a small garden, plentifully supported by white, and in a larger garden rose-coloured plants, with their white companion plants, may be the feature of some particular portion, not of course excluding other colours, but used—this rose and this white—so plentifully in their particular portion that a really striking effect could be obtained.

Now, early in the year, is the time to give these considerations due weight, so that, if needed, annuals can be reared to play their part in the general scheme.

Among the perennials double rose-coloured Hollyhocks, Phloxes, various Dianthus, Poten-

tilla formosa, Roses, and others make a splendid foundation, and many of the annuals ably uphold them and increase the grand decorative effect. Sweet Peas, *Agrostemma*, *Asters*, *Linum grandiflorum roseum*, Stocks, and *Phlox Drummondii* may be mentioned as among the most valuable.

In bedding out, one of the main considerations is to secure plants that shall flower over a prolonged period. The same consideration should receive due weight in planting a perennial border. When this is neglected, it often follows that the border lacks colour at a season when it is most necessary that it should be a brilliant mass of flowers. This point is one of the most important in selecting plants for a mixed border. Such a border ought to be far more beautiful and fifty times more interesting than the most elaborate bit of bedding. Think of the variety of plant life, of form, of habit of growth, of degree of maturity, and what these things mean to the real flower-lover! Make your foundation, then, back and front of your borders, of plants that flower over a really long period; they are to be found among the hardy perennials. Use them generously, and then for setting may come smaller quantities of the beautiful, but fleeting, subjects. *Practical Gardener*.

COLONIAL CORRESPONDENCE.

NEW SOUTH WALES.

RICHMOND RIVER.—The following extracts are taken from a private letter:—

Some of the forest trees here are magnificent, one tree especially, the "long Jack" or *Flindersia Oxleyana*, having lovely racemes of pure white flowers. Another fine shrub is *Helichrysum diosmifolium*, with pure white terminal bracts. *Acacia decurrens* has looked beautiful. A tree that grows well here, and is in great demand for tanning, is *Acacia pycnantha*—the best of all the Wattles for tanning. As to *Dendrobium speciosum*—the rock-lily, as it is called here—if you could make it flower in your houses as it flowers with us you would be delighted. Here it grows on the ground, on the trees, stumps of wood, in fact, anywhere you like to throw it down, no preparation of soils and situation being required.

In reference to the Pines they are planted 8 feet apart and 2 feet from plant to plant. They start producing fruit 18 months afterwards. When fruit is ripe the old plant throws out suckers, three or four the first season, and all bear fruit afterwards for several years. Then the plant becomes worn out, and suckers are planted between the rows. When these are established the old ones are rooted out, so that the ground is now idle. The third, fourth, fifth, and sixth years' growth produce splendid Pines, when, as I consider, the plants are in their prime.

I have grown some very fine Tomatos in 7-inch pots, and the old variety Matchless has been excellent. I had a splendid show of Cactus Dahlias: Mrs. Turner is a lovely yellow, and Earl of Pembroke I think one of the best dark; Starfish is most brilliant, standing 8 feet high, and I counted 27 fully expanded flowers on it lately. These are all good: Mrs. Carter Page, Vesta, Badinia, Olive, Cinderella, and Mrs. Sanders. F. A. K.

THE SUGAR CROP IN QUEENSLAND.

THIS has been a grand season for Queensland, indeed for the most of Australia, and the best for 25 years. Cane sugar yields in ordinary years from 12 to 15 tons to the acre, but this year from 40 to 50 tons per acre have been secured. Some of the crop will not be harvested for want of labour. This season a cane cutter can make 15s. a day, but he is not satisfied even with that.

PINEAPPLES IN QUEENSLAND.

I grow a few Pineapples for private use, about 320 comprising the whole of my crop. At the beginning of last winter a few small plants, planted only a few months, were in fruit. One

of these, a smooth Cayenne, was developing an enormous crown quite out of proportion to the size of the fruit, which was not more than a pound and a half in weight, so I cut off the offending crown, when the fruit began to swell as abnormally as the crown had done, and when ripe yielded a fruit weighing nearly four pounds. When I saw the progress this fruit was making, I cut the crowns off the other plants, and they all responded and swelled up; indeed, the "pips" of the Queen were nearly as smooth as those of the Cayennes, and the fruits were nearly as wide at their top as at their middle. By mid-winter most of the plants began to show fruit, and as soon as their crowns were 2 inches high, they were cut off, with the exception of a few of the bottom leaves. None of the smooth varieties are ripe (December 8), but I have been cutting fine Queens for the past month. Pines and Papaws (*Carica Papaya*) are the only fruits we have for use at present. I had a large crop of Peaches, but when the flying foxes found them, they cleared them nearly all off in two nights. Granadilla (*Passiflora quadrangularis*) will soon be in season. The foxes have now turned their attention to the Mangoes, which are ripening, and as the crop is small the foxes will have the biggest share. I informed a neighbour how successful I had been with seedling Pineapples. I had only 11 seedlings, and one has turned out a splendid Queen—sweet, rich, and with no core, but he did not consider that a success. He thought all the 11 should have been good varieties. The heaviest fruit weighed six pounds, but I have no doubt on scrub land it would have scaled 10 or 12 pounds. Our black soil is not suitable for either Pineapples or Grapes. One of my Pineapples was fastigiated, and measured 26 inches from corner to corner. *D. Buchanan, Mackay, Queensland.*

A ROCK-GARDEN IN NORTH YORKSHIRE.

LEALHOLME Lodge, a modern structure situated on the banks of the River Esk, about 10 miles from Whitby, on the Stockton and Whitby branch of the North-Eastern Railway, is one of the residences of Sir Francis Ley, Bart.

A more ideal spot for a rock-garden than the above would be difficult to imagine. Situated on the rocky banks of the River Esk, parts of which, to say the least, are majestic, the portion treated extends to rather more than half a mile in length. The work has been in course of construction for considerably over 12 months by Messrs. James Backhouse & Son, Ltd., of the York Nurseries, who have carried out the wishes of Sir Francis Ley in a highly satisfactory manner. Many hundreds of tons of earth and rock have had to be moved (the latter by the aid of ropes and blocks) at a considerable outlay. The formation of winding paths along the top and bottom of the slope with ascending and descending steps, intermediate walks, rustic bridges, and seats at intervals, give the work a most characteristic appearance. Owing to the great height of the bank, ranging from 60 to 100 feet from the bed of the river, and the steepness of the slope, the clearing away of the woodland undergrowth and the erection of a rustic fence as a protection to the uppermost path has been attended with a considerable amount of risk to life and limb, but not a single accident has occurred. The river hurrying along its course to the sea, here and there dashing itself against the huge boulders which lie in its way, and creating masses of boiling foam, adds still further to the beauty of the scene. A goodly portion of the planting has been completed; some 400 varieties of choice Alpine plants, suitable flowering shrubs and climbers, Conifers, and many varieties of suitable Ferns, along with about 20,000 bulbs, now find a home in this delightful glen. *J. Snell, York.* [We are indebted to the courtesy of Sir Francis Ley for the opportunity of giving two illustrations of this fine garden, which suggest pictures by Hobbema or Ruysdael.—Ed.]

THE ROSARY.

CULTURAL DETAILS FOR FEBRUARY.

ALL delicate and tender varieties should be well protected during severe weather. No pruning should yet be done in the open, however advanced the condition of growth may be, but in the case of half-hardy climbing varieties such as Gloire de Dijon and Cheshunt Hybrid, that enjoy the protection and shelter of a sunny wall, they can, if a few early blooms are desired, be pruned moderately at the end of the present month, but care must be taken to see that plenty of dormant basal eyes remain. The general pruning of Roses should be left until March and April, and, as most Rose growers are aware, those of moderate growth can be pruned closer than those of more vigorous habit. If some of the best ripened and strongest shoots of robust varieties that were formed last summer be pegged down by their points to the soil a few at a time during the early spring months, a good succession of flowers will be thus obtained. If the soil and the surface mulching have been beaten down by heavy rains, the ground should

pots. Good mellow loam, with a little rotten manure and some sharp sand, will suit their requirements. Make the potting quite firm, and, where possible, bring the union of the graft well under the soil.

Herbaceous grafting, both on the Manetti and on the seedling briar stocks, should now be well advanced, and with care few failures should be recorded. Shift the most forward plants, as they develop, from under the frames into the body of the house, and well up to the light on stages or benches over the hot-water pipes.

The earliest forced Roses will, by the middle of this month, be showing their flower buds, and with an increase of sunshine the temperature may be allowed to reach to 60°, with a little increased ventilation. Maintain a moist atmosphere, and syringe well among the foliage to cleanse it and keep down green fly. Allow the leaves to dry at some time during the day to aid respiration. Late potted Roses will now be growing freely. The Teas and Hybrid Teas can be placed at the warmer end of the house, where the temperature is about 55°. Give a little ventilation during the middle of the day,

FIG. 41.—VIEW IN SIR FRANCIS LEY'S GARDEN AT LEALHOLME, YORKS.

be lightly forked to allow the air to penetrate the soil, but care must be taken not to disturb the roots during the operation. On beds not yet permanently planted, a nice effect can be made with a few half standard plants of the varieties Captain Christy or La France, disposed at equal distances, with a carpeting at the base, of low, horizontally-trained plants of *Vicomtesse Folkestone*, *W. A. Richardson*, or *L'Idéal*. An equally good effect can be had with half standard specimens of dark varieties, such as *Dupuy Jamain*, *Prince Camille de Rohan*, or *General Jacqueminot*, with a ground planting of *Thalia*, *Aimée Vibert*, and *La Marque* trained like the preceding. Dwarf Teas and Noisettes can be planted out of pots later, during May, when all danger from frost is over, and selection should be made of plants carrying long, well-ripened shoots. Arches and festoons of Roses are a very pleasing feature where they can be trained or introduced to form a distinct effect and break up the formality of the beds. There is a wealth of choice amongst the rambling varieties, such as *Paul's Pillar*, and others.

The early batch of grafted Roses in 60-size pots will now be ready for re-potting into 5-inch

and, before closing the house, a light syringing of water overhead. Before and after the buds begin to show in the early batch of plants, weak liquid manure can be given once or twice a week, and for a change of stimulants a sprinkling alternately of Clay's manure or Canary guano. This is a wonderful help, and, in the case of root or pot-bound plants, quite a necessity. Hybrid Perpetual Roses require from eight to ten weeks, when not hard forced, to bring them into flower; Teas and Hybrid Teas from seven to nine weeks. It must be remembered that the harder the plants are forced, the poorer will be the quality of flowers; therefore, in order to ensure a succession of the best quality flowers, the heating and ventilation must be regulated to comply with these conditions. It is unwise under any circumstances, except with solar heat, to have the temperature above 65°, and then only at certain times of the day, accompanied by plenty of moisture. *J. D. G.*

COLOURED PLATES.

THE December number of the *Rosen Zeitung* contains coloured figures of *Etoile de France*, H.T., sent out by Pernet-Ducher in 1904:

flowers rich crimson; and Mme. Jules Graver-eaux, a Tea Rose, sent out by Messrs. Soupert & Notting, of Luxembourg: flowers flesh-coloured, deepening into pink. It is said to have originated from a cross between Rêve d'Or and Viscountess Folkestone.

VEGETABLES.

INTERCROPPING.

THERE are not many gardeners in private service who do not practise this method, if generally tentatively, and sometimes as a protection against the ravages of the wireworm, as when he plants or sows Lettuces alternately with the rows of Carrots and Parsley. But few adopt the method with most of their crops. It has, however, advantages in gardens of every

of the passage of a man in gathering the produce without injury to the adjoining crop. If sound Pea sticks are employed, no harm results to the haulm and the rows act as wind breaks, and the Pea plants pod splendidly owing to the freer access of sun and air on all sides; moreover, sparrows, crossbills, and other birds have much less covert than in dense quarters of Peas. In some parts of the garden not heavily manured, Broad Beans may be employed as dividing lines; in others, Runner, climbing French, and Wax (Butter) Beans may find similar employment. The Globe Artichoke, Cardoons, and Brussels Sprouts may also be employed in this way.

Some of the crops I have named do not endure for longer periods than two, three, or four months, whereas the adjoining land may be under a crop or crops seven to nine months, and the clearance of the land of the more fleeting

shoots are sure to attain to large size and the stools increase rapidly in strength.

There are many amateurs who are scared by the supposed expensiveness of Asparagus culture, and certainly the older practitioners believed the plant could not be grown successfully without immense quantities of dung being placed under it, and at depths where the roots could scarcely be expected to reach the manure. Trenching the land if it will bear it is good practice, and a layer of rich manure should be placed under the first and second spits; and the soil at the bottom of the trenches should be turned over, if the land is of a retentive nature and not properly drained. In sandy loams and light soils generally, this last is not to be recommended. Surface manuring should be practised in the second and following years, after clearing away the upper crust down to the crowns. This operation should be carried out late in the autumn, the soil removed from the ridge being cast into the trench on each side, there to remain, roughly dug, till early spring, when it should be thrown on the ridge to the depth of 3 to 4 inches, and be made smooth and level in the usual manner. The Asparagus being a plant which throws out new roots at a higher level each year, the stools approach nearer the ground level as time goes on, hence the ridge or bed gets higher than it was when planted, as soil must be got from the land adjoining wherewith to cover the stools, and all the more, if "long handles" are wanted for the heads.

Among the more short-lived crops which may be employed as interlining or "catch" one, mention may be made of Lettuces, Endives, Leeks, Shallots, Celeriac, Garlic, late sowings of Onions, Horn and other small Carrots, Turnips, Couve Troughuda, Parsley, Lamb's Lettuce, Rampion, and the earliest crop of Cabbages, generally a variety of small growth.

Kitchen gardens, pure and simple, when well and properly cropped, always afford satisfaction to the owner and his gardener, but they are scarcely satisfying to the æsthetic person. The orderly intermingling of crops in narrow breadths and plantations, whilst affording various useful purposes, do indeed add a certain degree of attractiveness to this useful adjunct to a country establishment. F. M.

WISLEY TRIALS.

WHENEVER in due course Onions form the subject of trials at Wisley, as several years ago they did at Chiswick, there will be for additional interest two or three so-called new varieties. It is the unfortunate characteristic of the Onion that very little that is distinct in its leafage is seen, and it is rather in the ripened bulb that any distinctions are to be found. But whilst no amount of testing or trials at Wisley will check the putting into commerce from time to time as new what are mere selections of well-known stocks, at least it is not the fault of the Royal Horticultural Society if full information as to the identity of the so-called varieties or the actual differences between them, or other merits if there be such, is not abundantly provided. Should an Onion trial be taken in hand next year, the beginning should be made by a sowing of every good hardy variety in August next, with in each case a blank drill adjoining, to be filled by transplanting from the sown drill next spring. The usual spring-sowing should be made in March, but again it would enhance the interest and value of the trial if seed of the same stocks of some 20 selected varieties were sown in January under glass and plants put out into vacant drills at the end of April, as is now the recognised custom in Onion culture. We should thus obtain a test of cultural diversity as well as of varietal value or distinctness. There is no reason why a breadth of ground previously manured and trenched specially for Peas should not do admirably for Onions. It is not at all needful to secure a good trial that giant bulbs be grown. Those of fine hard maturity will satisfy all needs. Happily at Wisley there is ample room for good trials, and as shown by the one of hardy, or so-called hardy Kales now seen there, very useful service can be rendered. The brief spell of hard weather at Christmas sufficed to show that all the broad-leaved Kales soon succumbed, the curled Kales proving to be much the hardiest. A. D.

FIG. 42.—WATER SCENE IN SIR FRANCIS LEY'S GARDEN, LEALHOLME, YORKSHIRE.
(For text see page 84.)

dimension; is not wasteful of space to any appreciable degree, if due attention be given to the size to which the various kinds of vegetables attain.

With regard to crops of low growth for which the demand is constant and considerable, as for Potatos, French Beans, Main Crop Carrots, Beetroots, Cabbages, Cauliflowers, Savoys, Onions, &c., these are more usefully planted in breadths stretching right across the various quarters, and not more than 20 feet in width, taking care that the various crops are sown or planted on land which has received the proper kind of manure, and a simple digging or trenching as may be considered necessary. Between these long beds I have found advantages in sowing two or three rows of Peas; and the interval between them need not exceed 4 feet for varieties with haulm of that height, and for tall varieties up to 7 feet, not more than 6 feet. There should be a 3 feet wide space on the outside of such interlining crops as will allow

plants permits of an easy succession by sowing or planting.

Strawberry beds consisting of five or six or more rows of plants of one variety may be divided from each other with any of the plants mentioned which are a good height, and derive benefit from the arrangement, partial shade being natural to a plant that is at home in open woods. The dividing strips assure all needful safety from the chances of getting the runners mixed.

Like many others, I can perceive no advantage in growing Asparagus in large quarters by itself, as better heads can be more easily obtained from single rows of plants set out on slightly raised narrow ridges, say, 3 feet in width, placed also as dividing lines between vegetable crops of low growth. The plants should be placed at 2½ to 3 feet apart; and seeing that, then no plant can rob another of its food, and the adjacent crops are grown at a distance of a yard or further on either side, the

NOTICES OF BOOKS.

FRENCH GUINEA.—M. Pobéguin has lately published through M. Challamel, Rue Jacob 17, Paris (Williams and Norgate), an *Essai sur la Flore de la Guinée Française*. It comprises some introductory details relating to the climate, the geography of the colony and its vegetable productions. It is a valuable addition to our knowledge of the West Coast of Africa, roughly, between 10° and 12° of latitude, and 13° and 17° of longitude abutting on the south on our own territories. A railway already extends 150 kilometres from Conakry as far as Kindia, passing through the coast region to the hill country, where it reaches an altitude of 1,000 metres. Here a town is rapidly rising, and the climate is not unfavourable to Europeans. Here caravans arrive from the north and from Sierra Leone on the south. On the coast the climate is equable throughout the year, with a maximum temperature of 35° C. (95° F.), and a minimum of 24° C. (75° F.), with excessive humidity in the rainy season.

At Kindia the climate is considerably cooler, and on the high plateau of the interior still more so. The rainy or winter season lasts about the same length of time as the dry and colder period; the rainy season, beginning in May, is at its height in July and August, when the rain falls every day. In October the dry season commences.

Owing to the configuration of the land and the differences in climate, the flora of French Guinea is more varied than that in the other parts of West Africa. M. Pobéguin divides the flora into five divisions, characterised by the presence of Oil Palm, the Raphia Palm, the Lami (Pentadesma butyracea), the Mènè (Lophira alata), the Iandolphia, the Calceolaria (Kaya senegalensis), in addition to which there is, of course, the vegetation which is common to all parts of tropical Africa. An account is given of each district, and an enumeration of the plants collected by the author. Unfortunately, a large proportion of these are indicated by numbers only, the species not being yet identified. A considerable number of Orchids is given, but with the exception of some species of Angraecum, Lissocilus and Eulophia, few present much attractiveness in their flowers. A map and numerous reproductions from photographs render this volume very interesting and important, although, as the author points out, it is to be regarded as an introduction rather than as a completed whole.

The Week's Work.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir Trevor Lawrence, Bart., Burford, Surrey.

As those plants like *Masdevallia ignea*, M. Lindenii, M. coccinea, and M. c. Harryana, and other strong growing kinds, and the small species and hybrids which were re-potted last autumn, are now re-commencing to root freely, and are developing young leaves, they will need a gradual increase of water at the root, and a rather moister atmosphere than hitherto. Plants that were not in a suitable condition for re-potting at the season mentioned may be treated now. Large plants that have become bare through loss of leaves in the centre may be divided, and be re-made up into good specimens. The lovely and white winter-flowering M. tovarensis may also be re-potted after the flowers have faded. If the spikes of the present year are not removed from the plant, they will continue fresh and green, and produce more flowers from the apex the following year. I do not advise retaining the old spikes longer than that, as they would tend to weaken the plant. Select shallow pans or pots of suitable dimensions to contain the plants comfortably, and fill them to three-fourths of their depth with drainage materials. Employ a compost of peat and sphagnum-moss in equal parts for the plant to root into. Water the plants sparingly till the young leaves are well advanced, for if kept too wet the old foliage is liable to damp off. A cool and shady position in the intermediate house is the best place for this species until the weather becomes decidedly warmer.

Vanda carulea.—Any plants which require more root-room should be taken in hand at once, as in a short time the young roots will

appear, and the least touch at their points would be likely to injure them. The plants of this lovely species, for a few years after importation, grow and bloom fairly well; then, in some cases, the plants gradually become weaker, and finally dwindle away altogether. Failure appears generally to be due to insufficient ventilation, too much heat and moisture in the atmosphere, or too much water at the root during the resting period. It comes from the Khasia hills in India, at an altitude of 5,000 feet or even higher, where there is no damp heat or stagnation in the air, growing on low trees fully exposed to all weathers, and where during the growing season the rainfall is excessive. The grower will thus have some idea of its cultural requirements under our artificial conditions. Wm. Griffith, the original discoverer of this species, describes the locality as "delightful, reminding one much of England."

Dendrobium Wardianum, *D. crassinode*, *D. Clio*, *D. Juno*, and others that commence to make new growths before the blooms on the previous year's bulbs are fully open, will require special attention, and the grower should do all that is possible to prevent these growths from advancing too rapidly, as they will do if excessive heat and moisture are afforded. Afford water only at long intervals until the flowers have faded and the young growths commence to root freely.

Other Dendrobiums.—*D. primulinum*, *D. Boxallii*, *D. crepidatum*, *D. cretaceum*, *D. Berkeleyi*, *D. crystallinum*, *D. superbum*, *D. s. Burkei*, and others which are showing their flower-buds, will now require more heat and moisture to enable them to become properly developed. *D. chrysanthum* and *D. chrysotis* (*Hookerianum*) are growing freely. The first-named species should be suspended in a light position in the warmest house, and the *D. chrysotis* requires a similar position in the Cattleya house.

FRUITS UNDER GLASS.

By ALEXANDER KIRK, Gardener to J. THOMPSON PATON, Esq., Norwood, Allon, Clackmannanshire.

Orchard house.—The trees must now be brought indoors. Examine the drainage material, and see that it is made effective. Make sure that the soil has not been soured by the winter rains. Re-pot those plants which were not potted last autumn. We obtain the best results from old trees when we treat them as follows.—They are turned out of their pots in October, root-pruned, the "balls" reduced, and planted in a warm, sunny border, where they remain during winter. They are lifted in January or February and potted into the pots of the same size as those they were fruited in in the previous year. We use good, heavy loam, chopping it finely, and adding a 6-inch potful of coarse grade manure to each barrow-load of soil. Potting is done firmly, leaving about 2 inches clear space for watering and mulching. A little water is applied to the roots to settle the soil. We wash each tree with caustic alkali, to destroy maggots and other insects. Some trees have to be pruned, but only moderately. The trees are eventually placed in the orchard-house, which has previously been thoroughly cleaned, and in some cases re-painted. The trees should be placed in the positions in which they will remain during the season. Keep the atmosphere of the house cool for the present by opening the ventilators night and day, but taking care to exclude frost. Early fruit can be obtained by placing a number of the plants in a house containing early-fruited Peaches.

Vine "eyes" that were inserted in pots or turves last month and placed in a cold pit should now be removed to a warm pit. Plunge them in a bottom heat of 80° to 85°, and maintain an atmospheric temperature of 60° to 65°. Be very careful not to apply too much water, as the strong bottom heat would cause the eyes to decay.

Ripe Grapes that were cut and placed in bottles of water in the fruit room should be examined twice each week, removing any decaying berries, and affording more water if necessary, being careful to see that the stem reaches into the water. Maintain an atmospheric temperature of about 45° to 55°. Grapes keep best in the absence of light, therefore on sunny days lower the blinds. Lady Hutt is the best keeping late white Grape, while Directeur Tisserand and

Lady Downes are the best keeping late black Grapes.

Peaches and Nectarines.—Trees that have set their fruits may be gently forced. If the weather is fine admit a little air by top ventilation only. Let the atmospheric temperature at night be 55° to 60°, and during the day by sun heat 70°. Syringe the trees freely with tepid water to free them of their old flowers. Disbud forward growths gradually. If there is a good set of fruit, thin out the smallest, and as the fruits advance in size thin them out by degrees. Test the inside border, and afford a soaking with tepid water when this is required.

PUBLIC PARKS AND GARDENS.

By W. W. PETTIGREW, Superintendent of the Parks and Open Spaces in the City of Cardiff.

Seats.—A good supply of comfortable garden seats is an essential requirement of every public park and their judicious distribution adds greatly to the comfort and convenience of visitors. Seats are as often as not merely "dumped" down at regular intervals along each and every path in a park, with but little, if any, consideration as to the suitability or otherwise of the site. There is a fitness of things in connection with the placing of a garden seat just as there is with everything else. It may not detract from the actual utility of a seat whether it is placed in such a position as to command a pretty view or overlook the entrance to a public lavatory, but it certainly makes a great difference to the feelings of those resting upon it. Experience teaches that there are many positions in public grounds where it is very inadvisable to place seats. They should never be in such a position as to hide out a clear view of a flower-bed or design, neither should they be placed in narrow footpaths, rock gardens, or ferneries, nor in secluded spots which are not much visited by the public. Then, again, many sites are suitable at one season of the year which are unsuitable at another; in summer and early autumn visitors generally prefer shady places to rest in, but in winter and spring they like the sunny spots which are sheltered from the cold winds, so that it becomes necessary to remove seats from time to time to meet the requirements of the seasons. As many of the users of public seats are in the habit of placing their dirty boots upon them, to the annoyance and discomfort of other people, it is always well to have a dividing arm in the centre of each seat. This not only prevents dirty boots from being placed upon them, but it also prevents one person monopolising a whole seat. In connection with the seating question, another matter arises which requires the careful attention of park attendants. These officials are, unfortunately, too often made aware of the existence of a depraved class of men whose whole aim and object in life seems to be the annoyance of females. As a rule, these persons are very difficult to detect, and, for very obvious reasons, still more difficult to convict, but where a number of seats in a park are set aside for the exclusive use of ladies, and have a notice placed upon them to that effect, then the attendants can easily see that no one using them is in any way molested by this class of individuals.

THE KITCHEN GARDEN.

By WILLIAM HONESS, Gardener to C. COMBE, Esq., Cobham Park, Surrey.

The severe frosts and the east winds that have been so general during the last week have considerably impeded the work in the kitchen garden. If there is still much ground to be dug or trenched, sufficient quantities of manure, wood-ashes, and extra soil, if necessary, should be wheeled on to the vacant ground for immediate use as soon as a thaw sets in.

Hot-beds.—Where these were prepared for the forcing of Potatoes, Carrots, Turnips, &c., as advised in a previous calendar, they may in some cases be found to have shrunk to a considerable extent, therefore additional linings should at once be applied of materials prepared for the purpose directly the shrinking was observed.

Cauliflowers.—Where sowings of these were made last month, the young seedlings should now be ready for pricking off, either in small pots or boxes; or if a frame on a very mild hot-bed can be devoted to them, so much the better

for the young plants. In either case, care must be taken that the plants are not "coddled," or allowed to get drawn up weakly. Make a further sowing at the present time to form a succession.

Seakale.—If this crop is being forced on the beds in the open, all the crowns that have been left for late supplies, and have not yet been covered, should now be given this protection from sunlight, for, in the event of warmer weather and the daily increasing duration of daylight, growth will soon commence. The natural purple colour of the growths would soon establish itself if light were not rigidly excluded, and such colour must by all means be prevented, or the Seakale would be useless as a vegetable.

Parsnips.—If the remainder of last season's crop are still in the open ground, the roots should now be lifted, and stored either in a shed or in a clamp, thus preventing them from starting into growth. Presuming the ground on which Parsnips are to be sown this season has received a good dressing of manure, which has been deeply buried, the seeds may be sown any time during the present month—indeed, as soon as the ground can be found sufficiently dry and in good order for the work. Preference should be given to a plot that has been previously occupied by Cauliflower or Cabbage, or some similar crop. Sow the seeds in shallow drills drawn at 18 inches apart.

The Root-store.—An examination of all roots should be carefully made during bail weather. Seed Potatoes should be well "picked over," and the tubers, if possible, spread out in a light, well-ventilated shed.

PLANTS UNDER GLASS.

By J. G. WESTON, Gardener to H. J. KING, Esq., Eastwell Park, Kent.

The Rose-house.—If not already done, this house should now be cleaned with a view to starting the trees into growth. Any necessary running (or in the case of climbing varieties running out of the shoots) may be done, and the beds or borders be afforded a top-dressing with some new loam; afterwards mulching them with some well-rotted manure. An atmospheric temperature of 45° to 50° will be suitable at first, but the heat may be gradually increased as the trees start into growth. Ventilate the house freely, as cold draughts are very injurious, and often favour the appearance of mildew on the leaves. Pot-Roses, in batches, for succession may be brought on in a fruit-house when the fruit trees are just starting into growth, at which time the same conditions will be suitable for the fruit trees and the Roses.

Hippeastrums (Amaryllis).—Seedling plants should be kept growing in a warm house, re-potting them into larger pots as this becomes necessary. Old plants that have been resting may now be cleaned up, re-potted if thought necessary, and placed in warmer conditions. It is usual to plunge the pots in a mild hot-bed, and in such a position the roots will only require very little water for some time to come, a slight spraying with the syringe being sufficient until the plants have made fresh roots.

Gloriosas.—These having been dormant for some months may now be shaken out of the soil and re-potted in a compost consisting of equal parts of lumpy peat, loam and leaf-soil, with sand and charcoal to keep the whole porous. Unge the pots in a hot-bed in a Cucumber or Melon house, applying no water until growth commences. When growth has commenced, in the shoots in a light position in the stove or other hot house, syringing them often to keep them clear of red spider and thrip, to which, if left in too dry an atmosphere, they would on fall a prey.

THE HARDY FRUIT GARDEN.

By J. MAYNE, Gardener to the Hon. MARK ROLLE, Bickton, East Devon.

Morello Cherries.—If Morello Cherries have not yet been pruned, let the work be done at once. The pruning of the Cherry is almost identical to that of the Peach, the major part of the fruit being borne on wood made in the previous year, although a good percentage is so obtained from spur growths. It must not be overlooked that the nearer the spurs are to a wall the better the chance of the flowers escaping spring frosts; therefore a few of the best spurs should be cut clean away each

year. It is the best practice to take the branches from the wall annually, so that they can be thoroughly washed, but time will not allow for this in all gardens, and since spraying is more generally adopted, there appears less necessity for this method. As a rule, the Morello Cherry is trained far too thickly, and instead of young shoots being 3 inches apart, half that distance is much nearer the mark on many a Cherry wall. Lay in each shoot its full length unless it be on young trees, and more wood is required to furnish the wall, when it must be cut back to where it is wished to have new shoots. We have adopted the plan of tying a young shoot on the old wood when it is not likely to interfere with adjoining ones, and are well pleased with the result. Morellos are sometimes grown as standards in the open. We have two nice young trees here which fruit splendidly, but we find much difficulty in preserving the fruit from the birds, enclosing the heads in a framework of wire netting alone baffling them. When pruning has been done, afford the borders similar treatment to that recommended for Peaches in last week's Calendar.

Pear trees.—Good varieties do not extend far into double figures, and it must be bewildering to a beginner to know which to choose from the long lists given in many nurserymen's catalogues. Williams' Bon Chretien, Marie Louise, Beurré Hardy and Beurré Superfin, Winter Nelis, Fondante d'Automne, Louise Bonne de Jersey, Doyenné du Comice, and Glou Morceau doubtless comprise the best of the varieties. Excellent fruits are to be had from pyramid and bush trees, especially early and midsummer varieties, but late sorts should be given wall space. In such a position the fruits can be allowed to hang well into November, with little fear of their being blown down or much bruised by the autumn gales. Upright cordons should be planted against suitable walls more frequently than they are, and with periodical root pruning or lifting they will usually bear well. The best fruits are obtained from trees growing in a strong, deep, loamy soil that is well drained. Trees may still be planted. Push forward the pruning of established trees should such work still be in arrear.

Severe frost.—On the night of February 2 we registered 18° of frost, which is greater cold than has been registered at Bickton for 16 years past.

THE FLOWER GARDEN.

By A. C. BARTLETT, Gardener to Mrs. FORD, Pencarrow, Cornwall.

The rock garden.—Frequent attention should be given to the rock garden, especially during the dull season. Remove all wind-blown leaves from the "pockets" and crevices, and pick out any weeds there may be among the plants, at the same time stirring the surface soil. Keep a look-out for slugs and snails, which are apt to prey on the young growths of many plants. Choice spring-flowering plants and bulbs which are coming into flower should be securely staked where necessary, and screened from rough winds by sticking a few sprays of some evergreen in the soil on the windward side. Fresh soil may, when required, be given to any of the later flowering subjects during suitable weather. Frequent top-dressings are not to be recommended, as this has a tendency to make the "pockets" too deep and to gradually hide the rocks, which should be kept exposed, or the rockery will lose its character. For this same reason the more vigorous of the spreading shrubs planted in the background should be restricted. Clear off the bulk of the mosses which have accumulated during the wet season, but encourage the various lichens to spread, for these give an established and natural tone to the boulders. It frequently happens that a few of the choicer Alpines have become weakened by the struggle to adapt themselves to the ever-changing conditions in winter, and scarcely possess sufficient vigour to live through the spring. If small pieces be taken from these invalids and potted in well-drained pots of soil containing more liberal proportions of sand and leafmould than usual, and placed in a cool pit, they will usually form healthy young plants for planting out at a later date. Gradually harden to the outside air those plants which have been wintered in frames, so that they will be in proper condition for planting out when circumstances permit.

Gladiolus.—Most of these should be planted this month, but a small proportion may be held back for a month or so, to yield a later supply of flowers. When Gladioli are used for bedding purposes, it is best to associate them with some other plants, such as Carnations or Cannas, so that there will be no blank when the Gladioli have flowered. For the production of exhibition spikes, and for supplying flowers for cutting, the corms should be planted in prepared beds of rich soil. Rub off the small corms, and, if it is desired to increase the stock, plant them in the reserve garden. In mild localities they may be wintered in the ground, and will bloom in three or four years' time. When liberally treated, the "Nanceianus" hybrids produce immense flowers of great beauty.

Lilium auratum bulbs may also be planted, using sound bulbs and allowing ample room between each for development. They must not be planted in exposed positions, and for this reason are frequently planted in Rhododendron and Azalea beds, and may also be effectively used in large beds of Yucca. Other species and varieties, such as L. Browni, L. longiflorum, L. Martagon, L. speciosum, and L. tigrinum, may with advantage be similarly used. Where L. giganteum succeeds, it repays for any trouble taken over it. The plant requires deep and rich soil, and generally some protection in the spring.

Sweet Peas.—A sowing of seeds should now be made in moderate heat. Various methods of doing this are practised, and of these the using of small pots, or of inverted strips of turf which have had most of the soil scooped out, may be considered the best. Seeds should be sown thinly, and when the young plants are an inch high, gradually harden them by increasing the amount of ventilation. Continue to draw the soil around the stems of autumn-sown plants. Afford stakes as soon as these become necessary, and for a further time retain the sheltering branches of Fir.

THE APIARY.

By CHLORE.

Why should we keep bees?—In the first place it is a fascinating hobby and one which pays. There are abundant statistics to prove this statement. Many cottagers almost rely on the bees to pay the rent, which may vary in the country from £5 to £10. The Irishman, when told to remove his pig from the house, observed that it was the "jintleman" that paid the rent, and objected to it being turned out. Now bees can be made to pay the rent with far less trouble and cost than the pig. Every year we import £32,000 to £35,000 worth of honey. The whole of this might easily pass into the pockets of our people if they would bestir themselves. The imported material is generally of a very low quality and highly adulterated with glucose, &c., causing people to take a permanent dislike to honey.

Honey as a food.—It is asserted by many eminent medical men that appendicitis is, in a measure, due to the large number of pills taken by our people. If honey were taken instead of jam, and even butter, happy results would follow. Sugar in some form is needed by the body to give warmth and nourishment, and as honey is sugar in one of the purest forms nothing could be better.

Bees aid in the production of fruit.—Many cases are recorded of the failure of the fruit crop, and where an investigation has been instituted into the cause, it has been found that the district has been insufficiently peopled with bees. This was the case many years ago in America. In districts devoted to the production of seeds, such as Turnip and Cabbage, nothing will make for success so much as the establishment of an apiary in the midst of the crops. If anyone desires to prove the truth of this assertion, that bees aid in the production of fruit, they can easily do so. Protect a small tree by means of a fine meshed net through which no bee can get. It will prove far less fruitful than its neighbours which are in the open. Further, during a wet and stormy May bees are often unable to visit orchards, and a bad fruit season is the consequence. Sometimes the fruits set under such conditions, but it will be noticed that they rarely mature, but fall to the ground. Should such fruits be examined, it will be found that the pips have not become plump, but are simply husks; this is due to improper fertilisation.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, FEBRUARY 12—

Ann. meet. of Royal Hort. Soc. at 3 p.m.; Coms. meet at 12 p.m.
British Gard. Assoc. Ex. Council meet at 4 p.m.
Horticultural Club ann. meet. and dinner.

SATURDAY, FEBRUARY 16—German Gard. Soc. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—38° 9'.

ACTUAL TEMPERATURES:—

LONDON.—Wednesday, February 6 (8 P.M.): Max. 40°; Min. 34°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, February 7 (10 A.M.): Bar., 29° 8'; Temp., 36°; Weather—Hard frost.

PROVINCES.—Wednesday, February 6 (6 P.M.): Max. 41° Ireland S.W.; Min. 23° Scotland N.E.

SALES FOR THE ENSUING WEEK.

MONDAY AND FRIDAY—

1,000 Roses, Azaleas, Lilies, Hardy Border and Herbaceous Plants and Bulbs, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.

WEDNESDAY—

Hardy Plants and Bulbs, Carnation Dahlias, Lilliums, &c., Palms, Plants, Azaleas, Aspidistras, &c., at 12; 5,000 Roses and Fruit Trees at 1.80 and 4.
2,171 cases Japanese Lilliums, and other Bulbs and Plants at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

THURSDAY—

Sale of Surplus Nursery Stock at Burnt Ash Hill Nurseries, Lee, S.E., by order of Messrs. B. Maller & Sons, by Protheroe & Morris, at 12.

FRIDAY—

Choice Imported and Established Orchids in variety, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

The Royal Horticultural Society.

In anticipation of the annual meeting, to be held on Tuesday, the 12th inst., the Council of the R.H.S. has issued its report for the year. The report is an eminently satisfactory one, as "the year 1906 has been one of steady progress in every direction." The principal event of the year was the Hybridisation Conference, so ably presided over by Mr. W. Bateson. Not since 1866 has such a successful gathering been held, and the council is fully justified in advertising to the matter with complacency. The next movement has been the actual commencement of the laboratory, a scientific research station at Wisley, of which Mr. Chittenden has, since the printing of this report, been appointed director. This will not appeal to the mere flower-show visitor, but if well conducted, its influence on horticultural progress must of necessity be very great. Setting aside for the moment pure scientific research, there are numerous questions that crop up in the course of the year which can, if sufficient support be forthcoming, be satisfactorily dealt with at such a station as Wisley. Numberless questions, as we know by experience, arise, from time to time, which cannot be answered offhand, but which could more or less readily be determined at an experimental station, such as we hope to see at Wisley.

In connection with this matter we trust that more attention and greater assistance will be given to the Lindley Library, especially as

the finances of the society are now in a satisfactory condition, whilst those at the disposal of the Trustees are exceedingly small. The library is large enough and important enough to demand the exclusive attention of the librarian, as provided for in the trust deed of the Lindley Library, a provision, from force of circumstances, never adequately carried out.

No fewer than six of the Victoria medalists have died during the year, and another must now be added to the list in the person of the late Sir Michael Foster. The vacancies have been filled by the appointment of Mr. Edwin Beckett, Dr. Augustine Henry, Mr. R. Irwin Lynch, Mr. Thomas Smith, of Newry, Mr. William Marshall, and Mr. Harry Veitch. That the two latter gentlemen should not have long since been entitled to call themselves V.M.H. is due to the fact that they were members of council. It is a wise regulation to prohibit members of council who have to bestow the honour on others from accepting it themselves, but it will also be generally felt to be wise that in exceptional cases like these the rule should not be enforced.

The total number of Fellows and Associates is now 9,467, no fewer than 1,207 having been elected in 1906, whilst 757 have to be deducted on account of resignations and deaths, leaving a net increase of 450 Fellows. We note that this is stated to be the highest number of subscribing Fellows belonging to any "Royal Society." How this may be we cannot say, but the Royal Society, as is well known, is limited in numbers, and not more than fifteen representatives of any and all branches of science can be elected in any one year.

The publication of Dr. Cooke's most useful hand-book of fungus pests is alluded to with natural satisfaction. Other details are given relating to the examinations, exhibitions, and meetings held by the society, the latter too numerous, by the way, during the winter months. Note is once more taken of the profusion of awards and medals granted by some of the committees. The excessive number of these, and the purely commercial value attached to them, at least outside, detract very seriously from the honour supposed to be conveyed on the recipient. If in the first instance provisional recommendations of a temporary character were adopted and registered, but not officially published, and confirmed or otherwise, as further experience might dictate, the numbers of these awards might be materially reduced, particularly if no award were made without a statement being made at the same time of the reasons for making it.

Wisley, apart from the experiment station, before referred to, is making satisfactory progress. A collection of Orchids is being formed, not by any means the first of the kind within our remembrance, but destined, we hope, to a longer existence and a more useful career than its predecessors. Over 9,000 visitors were enumerated at the garden in 1906, which, considering the difficulties and cost of access, is a large number, and must severely tax the patience of the courteous superintendent and his staff. We are but anticipating when, in closing this very satisfactory report, we, on the part of the

horticultural community, tender to all concerned, from the president, secretary, and council to the office staff, and that at Wisley, the most cordial recognition of the value of their services, and express the hope that they may be able to show as good a record in 1907 as they have done in 1906.

OUR SUPPLEMENTARY ILLUSTRATION presents a view of the avenue of "Talipot" Palms (*Corypha umbraculifera*) in the Royal Botanic Gardens, Peradeniya, Ceylon. These gardens have been described by tourists as "The garden of Eden," and are situated about 70 miles from Colombo, at an elevation of about 1,600 feet above the sea level. The area of the gardens is about 150 acres, and, as is to be expected from its equable climate, about 75° Fahr., the vegetation is purely tropical. In our issue for December 23, 1906, we published an account of the first Rubber exhibition held in Ceylon in these gardens, when many interesting details of the vegetation, &c., in the gardens were given. The following account of the avenue under notice is taken from Mr. H. F. MACMILLAN'S interesting *Guide Book* of these Royal Gardens, of which the author is curator:—"The noble Talipot Avenue was planted about 1885. This *Corypha umbraculifera* may be called the chieftain of the Palm tribe, attaining, as it does, to greater proportions of leaves and trunk than any other Palm known. The immense fan-shaped leaves are at their largest size when the plant is about twelve years old, before it forms a trunk; they measure several feet across and are largely made into fans, umbrellas, portable tents, &c. Known as "ola leaves" they have been used from time immemorial to the present day for writing native text upon by means of an iron stylus. The large hard seeds are made into buttons and ornaments. When from thirty to forty years old, the Palm produces from the summit an enormous canopy of creamy white inflorescence, followed a year or more later by ripe seed, and shortly after by the death of the Palm. Behind the Palms, on the right, are different kinds of Gutapercha trees (*Dichopsis*), and further back along the river bank are the principal rubber trees known, viz., *Hevea*, *Castilloa*, *Manihot*, or "Ceara rubber," *Funtumia* or *Kickxia* "Lagos rubber," *Mascarenhasia*, &c. On the left is the herbaceous ground, occupied by a large and interesting collection of herbs and undershrubs, all labelled and arranged according to their families; they include the powerfully narcotic *Ganja* plant, *Cannabis sativa*, and many others of medicinal and economic value."

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the committees will be held on Tuesday, February 12, and the annual general meeting will be held in the afternoon of the same day at 3 o'clock.

THE AMERICAN CARNATION SOCIETY held its meeting on British territory, viz., in the city of Toronto, on January 23, 24. Every preparation was made for a successful meeting, and we trust that nothing occurred to spoil what is after all a family party. Whether we islanders should care in mid-winter to take a journey of a thousand miles, to an exhibition and conference in such a climate, as some of our American cousins are prepared to do, is another matter.

NATIONAL FRUIT GROWERS' FEDERATION.—A meeting of the council will be held on Monday, February 11, at 2.30 p.m., at the Royal Horticultural Hall, Vincent Square. The business on the agenda includes a proposition by Mr. WAGHORN, that a special committee should be organised in Kent, to work in conjunction with the local authorities to obtain earlier delivery in London markets, and other improvements in the railway service (postponed from last meeting).

AN AVENUE OF YOUNG "TALIPOT" PALMS (*CORYPHA UMBRACULIFERA*) IN THE
ROYAL BOTANICAL GARDENS, PERADENIYA, CEYLON.

Photo by H. F. Macmillan.

Temple Press Ltd., Printers, 7-15, Rosebery Avenue, London, E.C.

THE BOTANICAL MAGAZINE.—This valuable publication is now issued under the editorship of Lt.-Col. PRAIN, the Director of the Royal Gardens, Kew. The plants figured in the February number are the following:—

NERINE BOWDENI.—W. E. Gumbleton in *Gardeners' Chronicle*, February 13, 1904; *Botanical Magazine*, tab. 8,117; *Flora and Sylva*, 1905, p. 120, c. ic., col.—A very handsome and distinct species of Nerine from the Cape Colony. Hort., Gumbleton, and Kew.

OLEARIA SPECIOSA (Hutchinson), tab. 8,118.—A new species allied to *O. dentata*, from which it differs in its oblong, elliptic leaves, smaller flowers, and almost glabrous seed-vessels. The branches and under-surface of the leaves are thickly covered with light-brown, felted hairs. The white flower-heads are in loose branching corymbs. It is a native of Australia and has flowered in the Temperate House at Kew, where it was received from the Melbourne Botanic Garden.

MECONOPSIS PUNICEA (Maximowicz), tab. 8,119 [also in *Gardeners' Chronicle*, October 22, 1904, p. 289, fig. 130].—A biennial species remarkable for its richly-coloured crimson nodding flowers and sessile stigma. The plant was introduced to the nurseries of Messrs. JAMES VEITCH & SONS from Western China by Mr. E. H. WILSON. The description now given is from the pen of Col. PRAIN, the authority on this genus, who contributed a monograph of the species to this journal on June 17, 1905.

RIBES MOGOLLONICUM (Greene), *Shan in Botanical Magazine*, tab. 8,120.—A native of the south-west United States, with palmate leaves, and erect flower-clusters, followed by purplish berries. The synonymy is very involved. The shrub is a native of the Mogollon mountains in New Mexico. We fear lest there may arise confusion between this name and *Magellanicum*. It was introduced to Kew from seeds sent by Mr. HENKEL, of Darmstadt.

SACCOLABIUM RUBESCENS (Rolfe), tab. 8,121.—One of the numerous novelties discovered in Annam by Mr. W. MICHOLITZ when collecting for Messrs. SANDER & SONS. It is allied to *S. ampullaceum* Lindley, but is more robust in habit and has much smaller flowers. Flowered at Kew and at Glasnevin. In the structure, but not in the colour of the flowers, it is like the species of *Angræcium*.

THE LATE SIR MICHAEL FOSTER.—A memorial service was held in St. James's Church, Piccadilly, on Saturday last, which the president (Lord RAYLEIGH), the secretary (Sir ARCHIBALD GEIKIE), and many Fellows of the Royal Society attended. It will be remembered that Sir MICHAEL was biological secretary to the Society for several years. The body of the church was filled, and among the members of the Scientific Committee of the Royal Horticultural Society, of which Sir MICHAEL was a vice-president, were present Mr. J. T. BENNETT POE, Dr. HORACE BROWN, Prof. FARMER, Dr. VOELCKER, Dr. HUGO MULLER, and Dr. MASTERS. Doubtless many others would have been present had it been possible to have announced the occurrence sufficiently early. A similar service was held in Trinity College Chapel, Cambridge, at which Lt.-Col. PRAIN attended. The funeral took place at Huntingdon.

PRESENTATION TO A GARDENER.—Mr. C. A. BAYFORD, for the past eight and a half years gardener to the Earl of LICHFIELD, Shugborough, Stafford, was presented with a clock by the Earl and Countess, on January 26, on his leaving Shugborough to take up new duties at Davenham, Malvern, the seat of C. W. DYSON PERRINS, Esq. The Shugborough Park Cricket Club has also presented Mr. BAYFORD with a diamond pin.

ROYAL METEOROLOGICAL SOCIETY.—At the annual general meeting of the Royal Meteorological Society held on January 16, Mr. RICHARD BENTLEY, the President, on behalf of the members of the council, presented an illuminated address to Mr. WILLIAM MARRIOTT in recognition of his services as lecturer for the society.

Kew BULLETIN.—It is gratifying to note the punctuality which now prevails in the publication of this interesting periodical. The first number for 1907 contains an account of the Cluster Cup (*Æcidium*) disease of Conifers, an article on the Chinese drug known as Tang-Shen, by Mr. E. H. WILSON, with an illustration. The drug is used in place of Ginseng, and consists of the dried roots of *Codonopsis Tang-Shen* of Oliver. The death of Lady BURDETT COUTTS affords an opportunity of noting her benefactions to Kew, including the gift of the late Mrs. GRIFFITHS' collection of British Algae and the Moss-herbarium of Prof. SCHIMPER. A list of plants suitable for cultivation in the warmer parts of the United Kingdom is given. The list is arranged alphabetically.

MITTEN'S MOSSES IN NEW YORK.—At the request of WILLIAM MITTEN, a chemist at Hurstpierpoint, Sussex, his great collection of Mosses, numbering at least 50,000 specimens from all over the world, was offered to the New York Botanical Garden in the Bronx Park for the moderate sum of £100 sterling and promptly accepted. One of the curators was sent to superintend the careful packing and shipment of the Mosses, and the collection is being arranged at the garden under the direction of Mrs. BRITTON, wife of Dr. N. L. BRITTON, the director, who is herself a specialist in bryology. The completeness of the collection, containing as it does specimens of the rarest kinds brought by SPRUCE from the Andes after his residence in South America, and other valuable species from Colombia, Ecuador, Brazil, Mexico, and the West Indies, as well as a valuable series of Arctic Mosses acquired during the early expeditions in search of the North-West Passage, now places the New York Garden in this department on a par with Kew and Berlin. MITTEN's first discoveries of Mosses in Britain began as long ago as 1842—he was 86 when he died last July—and in a few years' time travellers were sending him collections from various parts of the world, though his life was so secluded that he was personally little known and to comparatively few botanists. He received much encouragement from Sir WILLIAM HOOKER, who more than 50 years ago endeavoured in vain to induce him to take charge of his herbarium as curator in preference to that of a chemist's business at Hurstpierpoint, while for 40 years he was the friend of Dr. ALFRED RUSSEL WALLACE, DARWIN's co-discoverer, who married one of his daughters. MITTEN's own private copy of his "magnum opus," the *Musci Austro-Americani* one of the volumes of the journal of the Linnean Society, describing 1,750 species of Mosses, belonging to 127 genera, was sent by another daughter to Mrs. BRITTON in the execution of her father's instructions.

SCION AND STOCK.—The following note regarding the influence of scion on stock in grafting appeared in the *Botanical Gazette* for November, 1906:—By grafting *Nicotiana Tabacum* on *N. affinis* (which contains little or no nicotine), and *N. affinis* on *N. Tabacum*, GRAFE and LINSBAUER have succeeded in showing, in a more convincing way than before, the effect of the scion on the stock in respect to products of metabolism. Nicotin was found abundantly in *N. affinis*, whether it was functioning as stock or as scion. Indeed, it attained almost the maximum amount found in *N. Tabacum*, and scarcely fell below the limits of variation in that species. When *N. Tabacum* was the stock, and the scion, *N. affinis*, was cut away completely, the new shoots produced contained even less nicotine than the *N. affinis* leaves had; so that the authors believe the scion had even increased the capacity of the *N. Tabacum* stock to form this alkaloid. Further researches are in progress. *Agricultural News*, W.I.

CARNATION "SALMON LAWSON."—Messrs. HUGH LOW & Co., of Bush Hill, Enfield, send us a flower of a new Carnation, a sport from *Lawson*, but the colour is a delicate flesh-pink, and very pleasing. The flower has a slight fragrance.

JAMAICA.—The numbers of the *Agricultural News* for December 29 and January 12 which have reached us have a melancholy significance as containing a full account of the preparations for the Agricultural Conference, which was to be held at Kingston from January 11 to 17, and presided over by Sir DANIEL MORRIS. The conference, indeed, was in session when the terrific earthquake occurred. The principal West India islands were represented, and discussions on the cultivation of Sugar-cane, Cacao, Limes, Rubber, Cotton, &c., were to have been held, and papers read on the improvement of stock and the development of agricultural education. Excursions were planned to various parts of the island to visit the Banana and Tobacco plantations and other tropical cultures, including one of Pineapples. A portrait of Sir DANIEL MORRIS is given in the number for January 12, and it is believed that he, as well as the other members of the conference, escaped without serious injury. "The three main lines on which the most beneficial results will accrue to the inhabitants of St. Lucia, but doubtless they apply also (*mutatis mutandis*) to the other islands, are as follows: The adoption of measures to prevent tropical diseases, the general spread of knowledge of agriculture so as to prevent wasteful methods of cultivation and induce prosperity, and the general brightening of intelligence by sound utilitarian education."

NITRATE DEPOSITS.—There is a prevalent idea that the Chilean nitrate deposits will, at the present rate of working, be exhausted in the near future, probably within about 20 years. This estimate is based upon surveys and calculations made some 10 or 15 years ago, before a complete examination of the pampas outside the province of Tarapacá had been undertaken. In recent years, as we are informed, vast deposits have been discovered and surveyed in the districts of Antofagasta, Taltal, and Tocopilla, and according to the latest official estimates the store of "caliche" now known to exist and to be workable will suffice to meet all requirements of consumption during the present century.

LADY DOROTHY NEVILLE'S REMINISCENCES.—This is a delightfully unconventional record of past times with notices of scenes that Lady DOROTHY has witnessed and of people she has met. Lady DOROTHY has no little sense of humour, and was, and still is, ardently attached to horticulture. She was on friendly terms with many of its devotees, including GEORGE WILSON, ROBERT HOGG, HARRISON WEIR, and many others. Amongst other points of horticultural interest in her book, mention is made of a notorious swindler, whose wonderful productions were made the subject of a series of ironical comments in our columns by the late JAMES BATEMAN. It should be mentioned, however, that no exaggeration attached to the description of *Passiflora macrocarpa*, which was originally introduced by the late M. JEAN LINDEN. The very large fruits of this species resemble those of the *Granadilla*, *P. quadrangularis*, but are much larger, and the floral conformation is also quite different. As the flowers are handsome and the fruits excellent in a compôte, it is a pity this plant has almost dropped out of cultivation. Lady DOROTHY's garden at Dangstein was a home for many beautiful and interesting plants, the taste for which has been obscured by the preference shown to Orchids, plants suitable for house decoration, and such as furnish a continuous supply of cut flowers.

THE GARDENING YEAR-BOOK.—A book of reminders, telling the reader what he should do on each day of the year, circumstances permitting, is assuredly very useful, and when it is issued under the direction of Mr. GEORGE GORDON, the editor of the *Gardeners' Magazine*, the reader aforesaid may confidently rely upon the excellence of the advice given. A list of new plants of the past year is given, but is not so complete as it might be. There are excellent articles on the culture of fruits and vegetables, and a great variety of information likely to be serviceable to the gardener. It is published by Messrs. W. H. and L. COLLINGRIDGE, of 148, Aldersgate Street, E.C.

CROSS-BREEDING OF PINE-APPLES.—In the *Year-Book* of the U.S. Department of Agriculture for 1905, Mr. HERBERT J. WEBBER gives an account of the Pine-Apple breeding experiments carried out by that Department. All of the known varieties of Pine-Apple had some fault or faults which rendered them more or less unsatisfactory. It was desirable (1) that more varieties with smooth-edged leaves should be grown, since only one variety with this characteristic was known to the growers; (2) that more disease-resistant varieties should be obtained; (3) that the eating quality should be improved; (4) that better varieties for shipping should be produced. The pollen used was obtained by cutting off the flowers closely with short scissors. These clipped flowers were put in small labelled bottles until used. A fresh supply of pollen was collected each day. The process of crossing was very simple, as it is necessary to emasculate the flowers in the bud, on account of their being, as a rule, self-sterile. For the same reason, the flower heads were not enclosed in bags. In the process of crossing, the flowers, which scarcely open normally, were forced open slightly, in order to give easy access to the pistil. Pollination was then effected by rubbing open anthers of the desired variety over the pistil, from one to three anthers (the number depending on the abundance of the pollen present) being used on each stigma. Four years were required for the seedling plants to reach the fruiting stage, and it is thought that the best hybrid is the Miami, obtained from Enville crossed by Smooth Cayenne. *Agricultural News, W.I.*

THE ANTI-OPIMUM PLANT.—A paragraph has lately been the round of the Press relating to the discovery of a plant asserted to afford a remedy for the opium-habit. In the *Pharmaceutical Journal* for January 26, Mr. HOLMES, of the Pharmaceutical Society, announces the receipt of specimens from Perak, which show the plant to be a climber belonging to the family Combretaceæ known as *Combretum sundaicum*, of which a figure and description are given. Further evidence is required before the assertion of the medicinal virtue of the plant can be definitely accepted. All that can be said is that there is at present no satisfactory evidence that a *Combretum* possesses the powers attributed to it.

THE FIXATION OF NITROGEN.—It is greatly to be desired that the lay Press should avoid making sensational statements and refrain from the use of startling headlines relating to matters of which they evidently have little knowledge. The articles going the round of the Press on the utilisation of the nitrogen of the air make statements which are not new, while it is premature to treat them as wholly true. The production from the air of calcium cyanamide has now been known for some few years, and it has already been used experimentally and found to be about equivalent in value as a fertiliser to sulphate of ammonia. An attitude of expectant hope would seem to be the most appropriate feeling in which to indulge for the present.

THE SURVEYORS' INSTITUTION.—The next ordinary general meeting will be held on Monday, February 11, 1907, when a paper will be read by Mr. ALFRED A. HUDSON (Associate), entitled "The Ventilation of London."

FRUIT FARMING FOR PROFIT.—A fifth edition of Mr. BUNYARD's book with the above title needs no introduction, and, as we are told that the largest growers in Kent are constantly enlarging their acreage and the total quantity of fruit sent to market is much larger than it used to be, there seems to be no fear that fruit culture will be overdone, or that, in spite of cruel springs and occasional gluts in the market, it will, on the average of years, be anything but profitable. But growers must approach the business on modern methods, paying attention to the smallest details of cultivating fewer kinds that command a market value, adopting the best methods of grading, and by building up a reputation for honest packing and high quality. The Kentish practices, as here detailed, are worthy of the most attentive consideration. They are thus summed up by the author: "Grow few sorts, keep the trees well pruned and thin the boughs, manure freely and intelligently, and pack carefully." These four axioms, thoroughly carried out, will in a year or two more than double the proceeds from fruit-growing carried on in a slovenly manner. We heartily commend Mr. BUNYARD's lucid and well-reasoned treatise, based, as it is, on lengthened practice.

ALPINE PLANTS.—Mr. W. A. CLARK has published through Mr. UPCOTT GILL, Bazaar Buildings, Drury Lane, London, a second and revised edition of his handy little book on Alpine plants. The term is used in a wide sense, and the details of cultivation are just those which are required by the amateur. Useful charts are given by means of which the grower may see at a glance in what positions and in what soils to grow the plants, and how to effect the operation. An alphabetical list of suitable subjects is given, and selections for particular purposes afforded. The scheme of the book includes cultural details only.

CULTURE OF SWEET PEAS.

It has to be borne in mind in estimating the requirements of Sweet Peas what is expected of the plants. A long continued period of production is one essential, large blooms carried on very long stems is another, and slowly but surely the number of blooms expected on each spray is being raised to four. Culture has a determining effect on each of the above points.

There are, broadly speaking, two cultural requirements, the benefits of which it is hardly possible to overestimate. The one is an efficient root-run; the other, space for the plants to develop. Either of these may be provided, but it will serve no good purpose if the other is neglected. There are various ways of providing a suitable rooting medium. Some of my acquaintances remove the soil either wholly or in part, and introduce turfy loam and other expensive materials, but for ordinary purposes it is not as a rule necessary to go to so much expense. At the same time, it is to be remarked that a fertile and deeply worked soil is a necessity. But that can be secured by means of proper trenching and the addition of manure. The practice of bottoming the trench with a layer of manure does not commend itself to my mind as being the best method of presenting that material to the plants, though I do not doubt it may be a suitable way in certain soils and climates. A narrow trench I also deprecate, one 3 feet in width being well worth the extra labour involved. In trenching I prefer to incorporate rotted manure throughout the whole body of soil, mixing manure and soil

together in a rough but nevertheless an efficient manner. The result is that at no period is the plant underfed or overfed. The soil in these gardens being deficient in binding properties, I find it of not a little importance to make it firm as trenching is being proceeded with. This necessitates the ground being in a condition rather dry than approaching to a moist state, and therefore it cannot be cultivated unless in the former condition. Though it seems rather a paradoxical proceeding to loosen and break down soil at one moment and trample it firm the next, good results from such treatment are its justification. The good effects are a firm yet vigorous growth and the capability of the plants to pass through a rainless period without suffering from the experience. The other point, space, may perhaps be thought to be appreciated to so full an extent by all who grow Sweet Peas as not to call for special notice. Judging, however, by what I see and hear, those who appreciate the value of abundant space are in the minority. I have, indeed, had a clump of Sweet Peas examined by an unbelieving critic to satisfy himself that it was the growth of one seed only, and not of several, and over and over again persons have carefully inspected rows of Sweet Peas to make sure that the plants were set as wide apart as they were told. But the custom of allowing too little space begins earlier than at the planting stage. Again and again the practice of sowing several Peas in a small pot has been and is recommended, the resulting plants being planted out later. When raising Sweet Peas in pots for planting, I have never grown more than one plant in each pot. The benefit of this is most observable towards autumn when the single plant has greatly the advantage of those clumped, if they indeed survive till so late a period. Then in planting, many cultivators are so timid that they fear the plants will not fill up unless they are set only a few inches apart. Yet yearly the necessity of a wide space betwixt each plant is becoming more and more imperative, and the 9 inches which suited older sorts must be extended to meet the wants of such vigorous sorts as John Ingman, Queen Alexandra, Phyllis Unwin, and other recent novelties. I have decided to space all varieties this year at 15 inches, but the sorts will be strictly limited to the most approved and recent varieties as those above named, and Mrs. H. Sykes, Countess Spencer, Dora Broomfield, and a selection of novelties. These are so much superior to the older varieties that I am discarding most of the latter, including Lord Rosebery, Scarlet Gem, &c. R. P. Brotherton.

DECIDUOUS CALANTHES.

I ENCLOSE a photograph (see fig. 43) of *Calanthes* in flower at the present time in one of the plant houses at Oakwood, Wylam-on-Tyne. In my note on this genus, p. 411, June 27, 1903, I stated some of the difficulties experienced in the culture of these Orchids, and at the time those notes were written *Calanthes* were suffering from the effects of the black spot disease, which appears to be far more generally prevalent than I was aware of at that time. I had almost given up hope of having our plants in a healthy condition again, but we have at last overcome the difficulty, the result of which will be best shown by the photograph. As the plants will soon be passing out of flower, and will be placed under their usual resting conditions, some notes as to the methods followed may be of interest. I consider one of the chief factors in success is the proper hardening or ripening of the last season's pseudo-bulb, for if this is properly matured we shall undoubtedly obtain robust young growths at the proper season. As soon as the old flowering scapes have been removed, and the plants have cast their foliage, they should be turned out of their pots, the old potting compost be shaken away, and the roots severed to within about an inch of the base of the

pseudo-bulb. A shallow box, such as is used for seedlings, should be filled with chopped sphagnum-moss mixed liberally with coarse silver sand, and the bulbs duly labelled, placed in an upright position in the box, and secured at their base by a portion of the above-mentioned compost. The plants must not be placed too closely together, for the light must be allowed to reach each portion of the pseudo-bulbs, for which reason the boxes should be placed in a position where they may obtain the benefit of all the available light. If the sand and moss are reasonably damp when used, no more moisture will be needed, until the new growths make their appearance. The temperature of the house in which the plants are rested should not fall below 55° Fahr. As the season advances, and the atmospheric moisture is increased, the new growths will appear. The compost in the bottom of the boxes may then be occasionally moistened to encourage root development. The new roots make their appearance in some kinds almost as soon as the top-growths, but as they have the moist moss and sand as a rooting medium, it is advisable to allow some growth to develop before re-potting the plants. In potting, the pseudo-bulbs should be lifted with the compost adhering to their roots, for this will help

this stage that we experienced the greatest difficulty with spotting, and we found that by reducing the moisture on cool evenings, and by a judicious use of the top ventilators the last thing at night, this disease might be overcome. By the end of September, when the flowering scapes begin to develop, the blinds should only be drawn when there is a danger of scalding. This will help to harden the pseudo-bulbs as they mature, and will also help the development of the flowering scapes and will render them less liable to spotting. As the season advances, less atmospheric moisture will be required, but root moisture must be continued until the flowering scapes are expanded. A temperature of from 65° to 70° should be maintained. H. J. Chapman.

NAMING PLANTS.

In our number for January 12, p. 17, we gave extracts from the International Rules of Botanical Nomenclature as adopted at the Vienna Conference of Botanists in 1905. Those extracts related to points of special importance to horticulturists, as discussion on the subject generally is obviously more suitable for Botanical journals proper than for our columns. Dr.

"Furthermore, you wrote, 'Dr. Otto Kuntze did the same thing (set up rules of his own) and created synonymy by the thousand.'

"That is very wrong! I amended the Paris Lois only, as they were defective, and always with the aim to receive as few as possible changes of name. You are not able to show me *Deteriorations and Revolutions to the Paris Lois* in my *Codex brevis maturus*, by which more changes were caused, as necessary, by the Paris Lois.

"Therein (*Codex brevis*) are only *meliorationes necessariae et utiles* to the Paris Code.

"Synonyms by the thousand are only (are only) caused by Daydon Jackson's inept starting-point, now corrected, and the *Vienna Index inhonestans*, a very unfair thing, by which my correct names of plants cannot become synonyms.

"Well, you are a gentleman, and will not calumniate me, so you will correct yourself. And if you read my newest paper, I hope, also, you will write next time the contrary about *Briquet's Rules of Nomenclature* 'to be morally binding to all botanists'; for they are not internationally accepted, even not by the pseudo-international Vienna Congress; they are '*Regulae irregulares immatura Nomenclatura botanica Vindobonensis in Actis falsis*.' Otto Kuntze."

With this letter came a pamphlet bearing the title, "Motivierte Ablehnung der angeblich vom Wiener Kongress, 1905, angenommenen inkompetenten und fehlerreichen botanischen Nomenklatur-Regeln, sowie Vorschläge zur international endgültigen Reform auf dem Brüsseler Kongress, 1910, von Dr. Otto Kuntze, San Remo (Villa Girola), Italien, Selbstverlag des Verfassers."

We need only say that the pamphlet is a very interesting one to those concerned, and bears further testimony to the excellent motives, zeal, and unflagging industry of the author. Doubtless its proposals will be carefully considered and dealt with at the next Congress in Brussels.

NOVEMBER AND DECEMBER IN MY FLORIDA GARDEN.

(Concluded from page 69.)

FOLIAGE plants, like *Acalyphas*, *Codiaeums* (Crotons), and *Strobilanthes Dyerianus*, grow successfully around the house in rich soil. They make a glorious picture, and the Crotons, in particular, attain to a very large size, while *Acalypha marginata* and *A. musaica* often grow 6 to 8 feet high.

HIPPEASTRUMS AND CRINUMS.

Three genera are my particular favourites—*Hippeastrum*, *Crinum*, and *Caladium*; in fact, they keep up my enthusiasm constantly and absorb most of my time, my attention, and my interest from early in March to Christmas. The *Amaryllises* of the genus *Hippeastrum* are the first. The majority flower from March to May, and there are only a few kinds in flower at this season of the year. The fine old *Hippeastrum reticulatum*, and its hybrids, Mrs. Garfield, Mrs. Lee, Autumn Beauty, and others, all with dark green foliage, striped white, only bloom in November, but they need a good deal of attention and much coaxing to grow and flower well in Florida. At Christmas time different varieties of *H. aulicum* make a fine show in the garden. I find two particular strains of these plants only a success—the so-called *Amaryllis robusta* (*A. Rayneri*) and *A. Tettani*. Both differ but slightly in their habit of growth and in the form of their flowers. The growth is vigorous, and they multiply rapidly in rich, shady places. The second class of my favourites are the *Crinums*, of which I have about 50 species and hybrids. Their nomenclature, however, is in deplorable confusion. When the *Hippeastrums* have finished their flowering, the *Crinums* follow in rapid succession. Among autumn bloomers *C. amabile* is foremost. It is the giant of its class, growing from 4 to 6 feet in height, and the flower spikes are over an inch in diameter. The bunch of

[Photo by H. J. Chapman.]

FIG. 43.—DECIDUOUS CALANTHES FLOWERING IN MR. NORMAN C. COOKSON'S COLLECTION.

to preserve them from injury. A compost of the usual proportions of fibrous loam, peat and moss will be suitable, and it is well to mix a liberal sprinkling of finely-broken potsherds among the mixture to assist in keeping the rooting medium porous. *Calanthes* are generally considered shade-loving plants, and there are no Orchids whose leaves scorch more readily when in contact with the direct rays of the sun, but the material for shading should not be too dense. I think that with the use of a lighter shading material than is generally used the tissues of the leaves become harder, and are then not so liable to spotting. The leaves also are retained for a longer time on the plants when light shading is provided, many of them lasting until the flowers have expanded. The pseudo-bulbs also mature better with more light, and produce finer spikes and better quality flowers. During the season of active growth, the plants require a more or less humid atmosphere, and plenty of root moisture, especially when the receptacles have become filled with roots. Some reduction of the atmospheric moisture is necessary when the growth of the pseudo-bulb is finished. It was at

Otto Kuntze, therefore, must excuse us if we print the letter with which he has favoured us without further comment than that an opportunity will be afforded him at the next Congress to confirm or revise, as may be deemed proper, the "articles, rules, and recommendations" adopted in Vienna.

"In *Gardeners' Chronicle*, January 12, 1907, I read a paper of yours, *Naming Plants*. Therein are some mistakes, misrepresenting myself, which I beg to correct.

"Well, you wrote about the Lois de 1867: 'These have been followed with comparatively few exceptions, up to the present time.'

"That is wrong. Most botanists did not care at all about them, and I was the first who applied them consequently. As no date of beginning for genera was fixed, I followed the proposition of M. Daydon Jackson; starting point, of 1735. You see, I liked to agree with English. Thereby much more changes of names were caused than with 1737, and 1737 being the only scientific and most profitable starting point for genera, I accepted it in our *Lexicon generum phanerogamarum*. Where against 1753-54 for genera is a horrible fiction and mistake that I cannot accept as a scientific and honest man.

deliciously fragrant blossoms is immense—a "whole armful." No true Lily can rival in stature and beauty, in fragrance and massiveness, this magnificent plant. A large clump, consisting of a number of bulbs, as a large bed is a sight of real tropical luxuriance and beauty. *C. angustum* is smaller in all its parts, though similar. The flowers are smaller and much lighter coloured, but they are quite as deliciously scented as those of *C. amabile*, of which I had gigantic spikes in a large Japanese vase on Christmas and New Year's Day, filling the entire house with a strong and grateful perfume, not found in such profusion and aromatic sweetness in any other flower with which I am acquainted. *C. asiaticum* attains almost equal proportions. Its flowers are white, with a strong vanilla-like odour. It is scarcely ever out of bloom, and is much harder than the two former species. *C. giganteum* is naturally an autumn bloomer, pushing up numerous flower spikes in November and December. The pure white, bell-shaped blossoms emit a pleasing and strong perfume. This species is the most ornamental of all my *Crinums* in foliage, which is dark green, with a decidedly metallic bluish hue. Among Spider Lilies the African *Hymenocallis senegambica* is an autumn bloomer. Its large, white, strongly fragrant blossoms are more lasting than any other of its class. It is a strong grower and a very valuable plant for sub-tropical gardens.

CALADIUMS.

But the crowning glory throughout summer and fall—until Christmas—are the fancy-leaved Caladiums. They are like a dream in this dreamland. Their wonderful hues and colour combinations are a revelation, their luxuriant growth appears like a marvel, and to admire them in all their beauty they must be grown in large beds by themselves. They only luxuriate in the moist, rich soil near the lake, in the half-shade of a lath-house. Here they grow to a perfection which excites the admiration of everyone who sees them. In this country these grand foliage plants are very poorly represented in gardens, though the price of the finest sorts is exceedingly low. I had never seen a good collection while in the north, and those plants I saw did not arrest my attention. The first really fine plants I beheld here in Florida were on verandahs, and they at once aroused my enthusiasm. A few tubers of the most common kinds, set out in rich, moist soil, grew 3 and 4 feet high, and as much in diameter, and acted as a powerful incitement to enlarge my collection. At present there are about 60 different kinds in one large bed. They are closely planted—about a foot apart each way—and they cover the ground entirely. No weeds will grow underneath them. Before planting the ground was heavily fertilised with Painter's Simon Pine Brand, a fertiliser rich in ammonia, phosphoric acid, and potash. After leaving my couch in the morning, usually before or at sunrise, I wend my way to the Caladiums. The foliage is now covered with innumerable dewdrops, which look like pearls in the sun's rays. The many colour combinations, the different hues, and the bright reflections are wonderful in the extreme. The colours appear to be endless in their variety, and even among the foliage of the same plant the young leaves often are entirely different from the older ones. Most of them exhibit bright metallic hues, such as steel blue, golden and silvery tints, bronze and copper in the bright sunshine. Some look satiny, others velvety, and others, again, like mother-of-pearl. The leaves of certain kinds are quite translucent. And this beauty, unique in the extreme and glorious beyond description, keeps me spellbound for many a morning, for days, and weeks, and months. Nothing in Nature has aroused my admiration and my enthusiasm more than these glorious foliage plants. They are, indeed, like a dream of the greatest beauty. There is absolutely nothing—as seen here in our sub-tropical gardens—that can vi-

in gorgeous and endless beauty with the fancy-leaved Caladiums. All of them are beautiful, the species, varieties, and the oldest hybrids, as well as the newer introductions which Messrs. A. Bleu, Fred. Bause, Jacob Weip, A. Lietze, and others have achieved such success with. These plant-breeders have given us new combinations of colour in endless variety, and very frequently new forms and larger sizes of foliage. While I am admiring the beauty of my Caladiums in the early morning, the soft and salubrious air is full of fragrance, and the mocking bird's song from the top of an Orange tree near by, or the loud strains of the Cardinal Redbird from a dense Cedar or Cupressus torulosa falls on my ear, and the whistling notes of numbers of quails sound from the tall herbage of the near woodlands or the Orange grove. It must seem strange that the Caladiums can stand more frost than the Alocasias, Colocasias, Xanthosomas, Crinum amabile, *C. angustum*, and the Hedychiums, Cannas, and Bananas growing in their vicinity. While the foliage of most of the plants named is badly scorched or even destroyed by the first slight frost, most of the Caladiums have not suffered in the least. A few days ago I dug up a few of the largest specimen plants, Caladium Reine Victoria, C. Clío, C. Chantini, C. Wightii, etc. They had formed tubers as large as a soup plate and almost of the same form.

ROSES.

This article would be incomplete should I neglect to comment on the "Queen of flowers." Says Dudley W. Adams: "And Roses! Roses! Roses! I need not mention the Roses, for everybody in Florida has Roses and knows that they, too, are in 'all their glory' in November. Agrippina, Safrano, Isabella Sprunt, Catharine Mermet are of that vigorous habit that needs little coddling, but with plenty of good, hearty feed, and plenty of water, they will make wonderful bushes and bear loads of Roses. Some of mine are 8 feet high, equally loaded, and Roses, Roses everywhere!"

WILD PLANTS.

The woods are also full of flowers near my place. The Golden Rod, many Asters, different species of Coreopsis, Helenium, Eupatorium—mostly yellow and white—lend a wonderful charm to all the woodland scenery. In the garden, underneath bushes and trees, the ground is covered with the very conspicuous white blossoms of the Star Flower (*Houstonia rotundifolia*), which always clings closely to the ground, the blooms appearing as if they were set on a velvety mosaic of foliage. Another plant in full bloom now is the Blue-eyed Grass (*Sisyrinchium Bermudiana*).

THE BIRDS.

My garden is the favourite winter resort for many of the birds of my childhood days, albeit the most familiar of them all, the robin (*Merula migratoria*) and the dainty bluebird (*Sialia sialis*) scarcely ever enter the grounds. The robin is much persecuted by pot hunters, and is therefore very wild and wary, while the bluebird is a sojourner of the flat wood, far from human habitations. I hear their plaintive call-notes frequently, while they fly over the garden in scattered flocks. They breed here sparingly, but they never seek the society of man, as in the north, where they are the first birds to greet the settler when he moves into his simple log cabin. The Phoebe (*Sagormi Phoebe*) is, perhaps, the most common of the familiar northern birds in my garden, arriving late in October, just before the cold weather sets in, announcing its arrival by its characteristic notes sounding like "pe-wee." Catbirds (*Galeoscoptes carolinensis*), brown thrashers (*Taxastoma rufus*), song sparrows (*Melospiza fasciata*), chipping sparrows (*Spizella socialis*), house wrens (*Troglodytes aëdon*), all familiar northern garden birds, and many species of warblers make the dense Florida Cedars (*Juniperus barbadensis*), Cuninghamsias (*Cunninghamia sinensis*), Cupressus torulosa, C.

sempervirens, *C. Knightii*, *Magnolia grandiflora*, Wax Myrtles, wild Olives, Laurel Cherries, Orange trees, and other dense evergreens their favourite roosting places during the night; but they find particularly protection during cold weather in and among the soft, dense masses and festoons of Spanish Moss (*Tillandsia usneoides*), which, in exuberant profusion, covers most of our native forest trees. I have placed it on all the Oaks in my ground, but do not tolerate it on the choicer trees. Often the garden swarms in the morning with northern migrants. Though the weather is warm and beautiful, the air soft and invigorating, and the day almost an ideal one, I know that this sudden arrival of birds is a true sign of cold and stormy weather. Usually ten or twelve hours after these swarms of birds have appeared the wind changes to west, then to north-west, and the cold becomes intense, the mercury often falling from 80° F. to 40° F. in the course of ten hours. The freezing point is frequently reached, but really cold weather rarely sets in before January. Such a disastrous "freeze" as that of February 8, 1905, when most of the Orange trees were cut down to the ground—18° and 16° F. were recorded in the Orange belt—is happily something abnormal, and may not happen again in a lifetime. *H. Nehrling, Florida.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

THE ROYAL GARDENERS' ORPHAN FUND.

When filling up my voting paper this week for the election, it occurred to me that it was about this time 20 years ago that the suggestion to establish such a fund was first made. I looked up the volume of the *Gardeners' Chronicle* for the first half of the year 1887, and found the first suggestions were printed on February 12. A note from your office shows me that my note, under the present signature, was sent to you on the 5th of that month. The only object I have in penning this note is to say how thankful we horticulturists should be that so much real good has been done in the meantime to those who were in no way responsible for being left in this world without a bread-winner. Is it not possible for hundreds of gardeners to give their mite to the Fund who have not hitherto done this? I certainly think it is. There are over 100 children now receiving help. Surely there is enough public spirit and self-denial amongst gardeners to spare a trifle over one penny per week, and so double the number of recipients on the fund long before another 20 years has elapsed. I certainly think it is more from want of thought than want of heart that this has not already been done. *H. J. C., February 5, 1907.*

MICE ATTACKING VINES.—*H. C.'s* inquiry under the above heading brings to my memory the mischief caused by field voles in a vinery at Pencarrow, while I was foreman there, now many years ago. The vines were young ones planted in an outside border that was protected during winter by a covering of leaves, a few inches of the vines' stems being also covered with the leaves. A colony of voles made their home in the bed of leaves, and for some reason, perhaps mischief, for sharpening their teeth, or for use as food, cut the stems of the vines entirely through. I well recollect the perplexity caused by the vines not breaking into growth, and, though vexatious, it was a relief of much anxiety to me when the cause of the calamity was discovered, for it had been thought that a too strong winter wash had been used on the vines. *T. Coomber, The Hendre Gardens.*

About two years ago I had a similar experience to that recorded by *H. C.*, p. 79. One young vine was eaten off, and shortly after I heard something gnawing near one of the old vines at the point where it came through the wall, and when I examined it I found it was nearly half eaten through by a mouse of the same description as that mentioned by *H. C.*, and which was caught a day or two after. I quite expected to see the vine collapse later, but it appeared to make no difference in its growth, although the stem was eaten half-way through, but not entirely around. In my opinion the mouse had taken a liking to the freely-running sap. *J. Barnard, Mostyn Hall Gardens, Mostyn, N. Wales.*

VEGETABLE PRIZES AT SHREWSBURY.—No doubt vegetable exhibitors will welcome the proposed change in the value of the society's prizes for 12 varieties, and also the special prize offered for the best exhibit in the trade classes. This, however, can hardly be termed a champion class, as some have thought should be provided at this show. Suppose the finest vegetables are present in the best exhibit in the society's class for 12 dishes, this exhibit would be debarr'd from competing for this said champion prize, owing to there being 12 instead of 9 varieties. I think a much better arrangement, if a so-called champion class were desired, would be to offer the handsome sum now mentioned, viz., £20, as first prize for the 12 dishes in the society's class where no stipulations are imposed in respect to obtaining seeds from any particular seedsman. We should then have found all those who claim, or wish, to be champions competing together. Some of our best growers obtain their seeds from one firm only; therefore, they have no opportunity of competing for these handsome prizes. No matter how the prizes are arranged, they probably will not please all; but what I have suggested would open the channel for a real champion competition. *E. M.*

SELECT WINTER-FLOWERING CARNATIONS.

—I have tried over 50 varieties here this season, and the following are the best of their respective colours:—Robert Craig, Flamingo, and Challenger (scarlets), Harlowarden, Dabheim, and President (crimson), Enchantress, Mrs. Burnett, Fair Maid, Mad. Thérèse de Franco, Fiancée, Mrs. Lawson, Nelson Fisher, Mrs. Theo. Roosevelt, E. Crocker, and Floriana (shades of pink), Lady Bountiful, The Belle of St. Peary (white), Ceres and Aurora are two very good yellow grounds or fancies; Mrs. N. A. Patten, Lord Charles Beresford, Mrs. G. M. Bradt, and Prosperity, are worth growing. The following varieties have not answered expectations:—White Variegated Lawson, Hon. G. Fellows, Xmas Eve, Cardinal, Lottie Pike, Pride of Exmouth, and Mermaid. The best of the new ones at present are Britannia, Victory, and St. Louis (scarlet), Marmion (fancy), White Perfection, and Mrs. Norman (white). There are many more, which I have not yet seen. *A. E. Usher, gardener to Sir R. Baker, Burt., Ransdon, Dorset.*

PREVENTION OF CORRUPTION ACT.—"Herts (Employer)" raises an important question: What is going to be done with the 5 per cent. formerly given to gardeners? Surely we are not likely to hear of any unpleasantness as to how the spoils are to be divided. If employers would raise their gardeners' wages equivalent to the amount and deduct 5 per cent. from the account, or instruct all tradesmen to show with the receipts the amount of discount given to the gardener, that would surely end the matter. I think it is to be regretted that the noble lord quoted on p. 42 had not taken some such steps, thus setting an example to others. [The noble lord you speak of is famed for his justice and generosity. —Ed.] I strongly resent the suggestion that gardeners order more stores for the sake of discount than are necessary [so do we]. I find a difficulty in adding a few novelties without complaints of high bills. Surely now is the time for all gardeners who have not done so to join the British Gardeners' Association, for with the best feelings, and in the interests of both employer and employed, something can and will be done by co-operation amongst gardeners to improve the condition of the gardener. *Head Gardener.*

DISCOUNTS.—It would be interesting to know whether those nurserymen abroad (see p. 73) who are offering illegal commissions to the gardeners of England are aware that they are inciting the gardeners to commit a criminal offence. More is likely to be heard of the matter before long, but meanwhile it seems fair to point out that this behaviour of the foreign nurserymen in question furnishes one more cogent reason why English customers should be careful, in their own interests, to give preference to home-grown products. *H. Morgan Veitch.*

FROST IN CORNWALL.—The weather is very cold. On the morning of the 3rd inst. we registered 15° of frost, and on the previous days 14° and 19° respectively. Before that time and for four days the thermometer had not risen above 39° Fahr. On January 28 our minimum was 17° and maximum 27°. I have not known such cold days before in Cornwall. But the weather appears general. *A. C. Bartlett, Pencarrow, Cornwall.*

A NATIONAL VEGETABLE SOCIETY.—Mr. A. Dean is by no means alone in advocating the formation of a National Vegetable Society. It may interest your readers to know that the following well-known horticulturists have expressed themselves in sympathy with the idea in response to an inquiry from myself. The names are placed in alphabetical order: Messrs. Edwin Beckett, Elstree; C. H. Curtis, Brentford; Charles Daniels, Norwich; H. Dunkin, Hort. Instructor in Warwickshire; G. H. Hollingworth, Hort. Instructor in Gloucestershire; Philip Mann, Hort. Instructor in Buckinghamshire; Thomas Redington, Hort. Instructor in Yorkshire; John Smith, Midland Agricultural Institute; Robt. Sydenham, Birmingham; Harry J. Veitch, Chelsea; Horace J. Wright, Wandsworth; J. Wright, Pershore. The opinions of others would be of interest. *Walter P. Wright, South Eastern Agricultural College, Wye, Kent.*

BLUE HYDRANGEAS.—Mr. Brown's statements on this subject in your last issue are interesting. I have always understood that the colour of Hydrangea blossom is never blue except when the soil contains a large proportion of iron, but the example of blue and pink blossoms on the same plant given by Mr. Brown seems to point to the blueness being a sport, from which reversion is common. In the grounds of a little iron church close to my farm there are some splendid blue Hydrangeas, which came, I believe, from the nurseries of Mr. Knight, at Hailsham. There is a great deal of iron oxide in the soil here, and more in the subsoil. *William Bear, Magham Down, Hailsham, Sussex.*

—I have always found the deepest blue flowers on plants growing in comparatively poor soil, and in more or less shade afforded by tall-growing trees. We had a very fine specimen growing among various flowering shrubs about half a mile away from the pleasure grounds, which always produced intensely blue flowers, and, wishing it to be where it could be more frequently seen, I moved it into the flower garden, with the result that only a very slight shade of blue has been noted in the bloom since. Growing on an island, and heavily shaded by an adjoining Oak tree, every flower-head comes of a lovely porcelain blue; this plant gets no manure of any kind, except it be the fallen leaves of the Oak. Some few years ago this question was discussed in these pages, and I sent the Editor half-a-dozen heads from the first-named plant, and he remarked that they were the deepest blue he had seen. By the foregoing remarks it may be gathered that shade has something to do with the colouring of these flowers, and I am of that opinion, while others consider that sea air plays an important part in adding the blue tint. Be that as it may, it is a well-known fact that in Devon, also Cornwall and the Isle of Wight, this blue colour in Hydrangeas is very common. Locally, many a cottager gives them the name of "changeable," and they certainly do change colour with age. It may be noted that the water supply here is largely impregnated with iron. *James Mayne, Bickton.*

—The colour can be obtained by the use of powdered slate [as at Angers, France. —Ed.]. I saw some of a very deep blue in Hampshire a year ago produced by this means. Here we have large beds of Hydrangeas, in which some of the flowers are always blue and others pink, and the cause is put down to the presence of mineral matter in the soil. We have tin mines near, and there is an old lode running under these gardens, and the water that percolates through the rocky sub-soil is strongly impregnated. The underlying rock, too, is of a slaty nature, being known as clay-slate or shillet, and it would be interesting to know which is really responsible for this change of colour. The same thing is to be observed in other neighbouring gardens, but I have never yet noticed pink and blue flowers on the same plant. *F. Mark, Porthywidan, Devoran, Cornwall.*

RIBES AUREUM AS A STOCK FOR GOOSEBERRIES AND RED CURRANTS.—Fifteen years ago I procured through a German gardener 50 Gooseberry trees direct from Germany worked on Ribes aureum. The stems varied from 4 to 6 feet in length. Half of the number were potted and put in a new Peach house. These grew and made wood 18 inches long in the first year, being syringed and treated like

the young Peach trees. In the following February they were started with the Peach trees, and they produced enormous crops of fine fruit, which ripened about the end of May and beginning of June, and were greatly appreciated for dessert. The trees remained in the same pots for five years until the Peach trees had covered the trellis overhead. I then planted the Gooseberries out in a covered-in fruit garden, and planted them against the iron standards which support the wire netting, where, with the others, they have cropped splendidly, better than the trees on their own roots growing beside them. I have watched them very closely for mildew, but have never seen any on them. The two faults I must find with them are that the stock throws such a quantity of suckers, and that the stems snap asunder so easily if the ties get broken. I have raised a new stock simply by saving some of the best suckers, being careful to remove every bud I can see at the roots, and simply budding in the summer as is customary with Roses or fruit trees. *A. W., Caterham.*

GOOSEBERRY-STOCKS.—It is a fact that Ribes aureum is used as a stock for standard Gooseberries, and equally true that one of the firms named by W. (see p. 60) send out plants budded or grafted on it. There are in this garden two or three such plants, which annually throw up suckers from the base of the stocks. And of those which appeared several years ago, some were taken off and grown on, and have since flowered in the shrubbery borders, leaving no doubt as to their identity. Few practical growers will support the practice of growing Gooseberries on standards, especially if budded on Ribes aureum, for, although this species makes a tall, clean stem, its girth increases so slowly as to always need a stake, and this, to support a heavily-laden "head," must be a thick one, imparting a clumsy appearance to the whole. Dessert fruits from standards are not superior to those grown on bushes. The best fruits are produced from the young growth of trees trained on trellises or wires. For the bush or trellis plant a "stock" is quite unnecessary. There is, therefore, no good reason for introducing Ribes aureum to our Gooseberry plots. *J. Comber, The Gardens, Nymans, Crawley.*

RATS AND PHEASANTS.—In reading Mr. Macdonald's note, p. 46, I wondered whether he has tried "Liverpool Virus" for destroying rats. I have found it an excellent destroyer of these pests if used according to the directions given, and as it is harmless to pheasants and other animals excepting mice it is a valuable substance to use in a garden frequented by game. I have to use Pea guards to protect Peas and all kinds of Beans from pheasants. I notice their favourite time for visiting the garden is in the evening before they go to roost, and in the morning when they come down from their perch. It seems as though they like a dainty supper and a delicate breakfast, or perhaps they go where they can get one most easily, for in the middle of the day they are busy hunting in the park. *V.*

PHEASANTS AND PLANTS.—I am enclosing a few growths of Carnations which have been injured by pheasants. I have been greatly troubled with these birds, and at first I attributed the injury to mice, but as I only caught one or two of these animals I thought it was sparrows or possibly a rabbit that was doing the damage. I was puzzled by seeing much of the foliage after it was plucked lying close to the stem and dropped upon the ground, but at last I found the culprits at work and they were pheasants. In May and June I found them most troublesome; they would be round the plants both early and late, so I put some netting over the beds with sticks to keep it clear of the plants. On one occasion a fine cock pheasant found his way through the netting into a bed, and he also found his way out before I could catch him. These birds are also very fond of Tulip bulbs, and if they find them near the surface of the ground they soon clear them all out. I have had to discontinue planting double Wallflowers on account of these birds, which pick off the flower buds as they expand. I have known them to eat the heads of Broccoli and also Lettuce, and they do not object to a few green Strawberries or Apples. *J. Barnard, Mostyn Hall Gardens, Mostyn, North Wales.*

TAR AS AN INSECTICIDE.—I have read with interest the articles on gas tar as an insecticide, pp. 45-60, for use on vines infested with mealy-bug. I have proved this substance to be most effectual and safe, and practise the following method of applying it. After pruning the vines I remove all loose bark and thoroughly wash the rods two or three times with strong paraffin soap, at the rate of half a pint of soap to one gallon of warm water. I next procure some clay and mix it with water to the same consistency as paint, and to one gallon of this mixture add one half-pint of gas tar and well mix the whole. The tar and clay is applied to the vines with an old paint brush, with which the insecticide is rubbed well into all crevices of the vines. I paint the buds also, for I find it does them no harm, the only effect being to retard them for a few days when breaking into growth, which is of little importance compared to ridding the vines of a troublesome pest. Tar is also valuable for keeping wasps out of fruit houses. It should be placed about the houses in vessels and stirred occasionally. Mr. J. A. Huntley states, p. 60, that vines were killed by petroleum. I have seen vines killed by petroleum through using it when the vines were dormant, but it is perfectly safe to apply when the tissues are filled with sap. I have seen excellent results from the use of this fluid. Some badly infected vines were washed with ordinary insecticide, but the bug was not killed. I tied the young growths down, and applied neat petroleum to the old wood, at intervals of about a month. After using the petroleum three or four times not a bug was to be seen. When the vines are in a dormant condition at their roots, the fluid finds its way into the tissues of the vine, and of course failure results, but when the sap is up, it cannot penetrate into the plant, and can then be used with safety. *P. Wilkinson, Hylands, Chelmsford.*

GAS TAR ON FRUIT TREES AND BUSHES.—Discussion on this subject is highly desirable. I should be glad to know if any reader has tried diluted gas tar sprayed on Gooseberry or Currant bushes or Plum trees, to prevent birds from eating the buds. If it would not harm the bushes or trees, it would probably be much more effectual than any mixture containing lime, because it would stick on the buds longer. Possibly also it might prevent the hatching of aphid eggs on Plum and Apple trees, and the eggs of the Apple sucker on the latter, if it did not actually kill them. It is to be presumed that, if safe to use at all, diluted gas tar would be so only when trees and bushes are dormant, as I take it for granted that to coat foliage with it would be highly injurious. Otherwise it might be used to kill or disgust the aphid when actually attacking Plum or Apple trees, which nothing yet tried by me does effectually. Last season I sprayed Apple and Plum trees twice, and in some cases three times, with a strong solution of quassia and soft soap; and yet the aphid attack was only slightly mitigated. A much weaker mixture effectually kills the Rose aphid; but Plum and Apple aphides appear to wear waterproof coats. *South-East Sussex.*

APPLE MINCHULL CRAB.—At the recent meeting at Vincent Square, members of the Fruit Committee were somewhat puzzled over a very fine sample of an Apple shown by Earl Stanhope's gardener, Mr. Sutton, from Chevening Park, and named Minchull Crab. Eventually it was found that the fruit was that of Annie Elizabeth, being conical, well coloured, firm, and handsome. Of all the late Apples grown few can excel this variety for sample of fruit, keeping, or quality. The fruits of the true Minchull Crab are broad and flattish, also green in colour. Old Rogers described them as resembling those of the Deux Ans. The tree is very hardy, never subject to canker, and has a spreading growth. Annie Elizabeth has erect growth. Minchull Crab, like so many other old Apples, has been displaced by much better ones. *A. D.*

MALFORMED CYCLAMEN.—I have a Cyclamen in flower at the present time, and on one of the peduncles, instead of the usual petals, there appears a branch. It has already produced two leaves and two rudimentary leaves. There is a space of half an inch between the two nodes. In the axil of the lower leaf a small spine or hair-like structure appears. Underneath the upper leaf are two roots half an inch long. By its general appearance one would think it is about to form a corm. Is this a common occurrence? *D.* [We occasionally see similar ones.—*ED.*]

THE CATTLEYA FLY.—Among the Cattleyas and Lælias this is well known to be a very injurious pest. Its presence is easily detected by the unusual swelling of the young growths when the latter are a few inches long, and if steps are not quickly taken to eradicate it many plants will soon be disfigured. Opinions differ regarding the remedy best to adopt to dispose of this unwelcome intruder. Some recommend the cutting away of the young growths as soon as the unusual swelling is perceived. This I consider the wrong course to adopt; it is quite unnecessary. If only one or two plants were attacked, and one were quite certain that no flies were living in the house, then the cutting away process would be advisable. But if numerous plants suggest signs of their recent visitation, that is evidence that there are flies still living, and as long as living flies remain in the house, one might cut away all the young growths and still be no nearer exterminating the pest than at the beginning, for as other growths are made their work will be carried on as before. The Cattleya Fly, like many other winged insects, may be quickly killed by fumigation, and I have found by experience this is the best remedy to adopt. Though rather expensive in the first place it is cheaper in the end. As soon as it is seen the destructive visitor has arrived, fumigate the house with Richards' XL All Vaporiser twice a week for about five months; any flies present will be killed. Before five months have elapsed all eggs deposited will have changed into larvæ, passed through their various stages, and, becoming flies, meet the same fate as their predecessors. Eight years ago most of the Cattleyas and Lælias in one house here were affected with the Cattleya Fly in a manner I think seldom seen; nearly every young growth had been cut away with no good result. We left the plants entirely alone, and commenced to fumigate with the XL All Vaporiser, and continued the practice for about the time above-mentioned, and not a vestige of fly has ever been seen since. The repeated fumigations during that time caused no injury to the plants whatever. The house then contained Cattleyas, Lælias, Oncidiums, Epidendrums, Miltonias of the spectabilis section, Aërides, Sobralias, Cœlogynnes, Odontoglossum citrosimum and O. Londeboroughianum, Schomburgkias, Lycastes, Brassias, Brassavolas, Dendrochilums, and Zygopetalums. *F. W. Thurgood, Rosslyn Gardens, Stamford Hill, London, N.*

STARTING EARLY PEAS ON TURVES.—Although this is an old method, it is a very good one for the gardener who likes to obtain for his employer a few early Peas, especially if adopted in a season like the present, when early planting cannot be recommended, more especially on heavy, cold soils. The time is fast slipping away, but even now it would be an advantage, especially to privileged gardeners who can get plenty of good fibrous turf. The turves should be cut from 1 foot to 15 inches long, and about 8 inches wide; then, if the turves are about 4 inches deep, scoop out about 2 inches of soil through the centre about 5 or 6 inches wide. Sow the Peas, and cover accordingly. The turves should only be placed in very moderate heat. After the seedlings are through and the surface ready to be moved, they should be put into a cold frame, and protected for a time. Gradually but thoroughly harden them off before planting them into prepared trenches. Place sticks to them at once, and protect them with black cotton to keep birds away. I am adopting this method rather largely this season, and the varieties I am planting are English Wonder and May Queen. *W. H. Collett, The Gardens, Huntsham Court, N. Devon.*

CHRISTMAS ROSES: A WARNING.—It has often happened during the early months of the year, when Christmas Roses have been shown in flower at the meetings of the Royal Horticultural Society, that advice has been given to the effect that a good season for re-planting, or dividing and re-planting is so soon as the flowers are over, or when new growth begins. I desire to anticipate such advice being tendered and to utter a word of warning to intending planters. They should wait at least until the end of August next before attempting to plant Hellebores. Two sets of root fibres only are made each year by these plants: 1, the main roots late in summer or early in autumn, and 2, the smaller fibrous roots which form upon the main roots, and which appear about the same time as the new leaves. The matter would be of less importance if these main roots, once broken or cut

off, sent out secondary roots as do many plants, but they do not. Much more frequently when broken or cut in their youthful stages these roots turn black and perish, often to the crown. In this way both sets of roots are sacrificed or much reduced in value, the result being that for nearly a year the plant lives upon itself, so to speak, and therefore is described as "impatient of disturbance." The Hellebore is impatient of disturbance—at a wrong season. *E. H. Jenkins, Hampton Hill.*

SEVENTY SEED PODS ON BEGONIA GLOIRE DE LORRAINE.—Since my calendarial note appeared in the pages of the *Gardener's Chronicle* on December 15, page 406, I have had many enquiries as to the seeding of this Begonia, and up to that time it seems to have been almost unknown that this variety would reproduce itself from seed. I have read with much interest the notes from various correspondents and their discovery of seed pods. In the year 1899, and just previous to his death, my late-lamented friend, "Mr. James Martin" (of Messrs. Sutton's, Reading), mentioned to me that he had found a seed-bearing pod of Begonia Gloire de Lorraine. I felt assured afterwards that the plant would reproduce itself from seed. Now that this is an established fact, there should be no difficulty in procuring seed, which, as stated in my note, and which is based on close observation, will produce plants of a more vigorous habit of growth, and superior quality of bloom also. I have now 70 seed pods, and all are produced on the terminal or last-developed flower. The difference of the male from the female flower is that the latter is quite a round-petaled flower, and has five petals [and a three-winged ovary beneath the flower], while the male flowers have only four petals. This fact will materially assist the uninitiated in finding the seed-producing flowers in both the white and pink varieties. I am much interested in Mr. R. Goodbourn's notes respecting the individual flowers of a variety of B. Gloire de Lorraine 2 inches in diameter. If he succeeds in raising plants of this from seed, they should produce exceptionally fine flowers. *B. Cromwell, Cleveley Gardens, Allerton, Liverpool.*

—I may say without fear of contradiction that I introduced this variety to the district of Liverpool some eight or nine years ago at the Horticultural Society's Show, with a view of instituting a class for competition. At that time I had several very fine pods of seed, fertilised by their own pollen. But professional teachers pronounced the raising of seedlings to be impossible, and I am sorry to say my interest disappeared. Mr. Cromwell appears to attribute the seeding of his plants to having them in a somewhat dry structure. I do not think that alone is the cause. I would rather say the infrequency of seeding is owing to the paucity of female blossoms, and I venture to say female flowers are never produced until the end of the flower raceme is reached, and not in all cases even then. This shows that nature provides a means of perpetuating the plant. I have the variety seeding at present from cross-fertilised flowers. *W. B., Carnatic Hall Gardens, Liverpool.*

SUTTON'S GARDEN SWEDE.—We have given this vegetable a trial, and find it a valuable addition to the root-store. Field Swedes are usually strong in flavour, but the yellow variety as grown in these gardens is as mild as the best of Turnips, and the tops being particularly short require no more space than do the latter. They withstand severe weather better than Turnips, so may be left in the ground until quite late in the spring. The seed should be sown towards the end of July or quite early in August, as the Swede requires a long season of growth. *James Mayne, Bickton Gardens, Devonshire.*

INCREASED APPRECIATION FOR FIGS.—The Fig has a great future in front of it, and for growers in this country. It has so far occupied in the public esteem a similar position to the Tomato of some years ago, which was formerly only appreciated by a few, but is now a popular favourite. The Fig is rapidly becoming a popular fruit, and only needs to be put on the market in sufficient quantity to be somewhat reduced in the price at which it is now offered, and I firmly believe we shall have it as popular as any other fruit, not excepting even the Tomato or Banana. *Laurence J. Cook.*

BLUE WATER LILIES.—The chief drawback to these lovely flowers is that the plants lack the hardiness of the *Nymphaea Marliacea* hybrids, and therefore perish during the winter if not lifted from the ponds and kept in a warm tank during the winter. In many cases they have been flowered in the open water during the summer months even where the water has not been artificially warmed, and in small tanks, through which hot water has been kept continually running, they have remained alive through the winter. According to *Nicholson's Dictionary of Gardening* the blue Water Lilies are *Nymphaea gigantea*, Australia; *N. scutifolia*, Cape of Good Hope; *N. stellata*, Tropical Africa; and *N. zanzibarensis*, Zanzibar. I note that Mr. James Hudson writes: "N. scutifolia is only a varietal form of *N. stellata*, so far at least as I have been able to form an opinion." It will undoubtedly be admitted by all those interested in horticulture, that if a race of blue Water Lilies sufficiently hardy to withstand the cold of winter in the open water, as do the Marliac hybrids, were introduced, water gardening in this country would gain an added charm, and from the remembrance of visits paid to the Cape some 25 years ago I should say that a hardier variety might be easily obtained. Between Cape Town and Port Elizabeth lie the Outeniqua Mountains, a coastal range, distant from five to ten miles from the sea, from which, every few miles, a clear river flows downwards to the shore, and in these rivers a blue Water Lily, probably *N. scutifolia*, grows. The mountain range is quite low. I should say, from recollection, that the loftiest peaks do not exceed 4,000 feet in height, and every winter they are covered with snow, while in a paper I received a few months ago a heavy snowfall was recorded in the town of George, at the foot of the mountains. Even in February, which is practically mid-summer, the temperature by the water-side in the River Kloop fell very low at 2 a.m., as I well remember, and in the winter the cold immediately around these Lilies must be considerably more severe. Under the circumstances I cannot but think that Lilies imported from this district would prove far harder than those at present under cultivation in this country, and that they would probably pass the winter without harm in sheltered water in the south-west. I remember seeing these Lilies in beautiful flower close to the ford by which I crossed the little River Goukamma, distant a few miles from Knysna. S. W. Fitzherbert.

HISTORY OF SAXIFRAGA BOYDII.—The mention on p. 440, December 29, of this beautiful plant in the obituary notice of the late Mr. J. B. Boyd, in whose garden at Cherry Trees, Kelso, N.B., it originated, induces me to pen a further note concerning it. In my articles on the yellow-flowered Saxifrages in the *Gardeners' Chronicle* in April and May of last year I quite forgot to mention the first coloured plate that was given of *Saxifraga Boydii*. This was published in the issue of *The Garden* for July 6th, 1890, and from the text accompanying this plate it is almost certain that Mr. Boyd believed its parentage to have been quite different to that now generally accepted, and Mr. Boyd's opinion held good until the plant first flowered at Kew, when the late Mr. D. Dewar, who at that time had the care of the herbaceous department in that establishment, suggested the parentage now believed to be correct, which is cited in the *Kew Handlist* of hardy plants. This flowering at Kew naturally took place several years after the plant appeared at Cherry Trees, so that even to-day the history of the plant is founded on conjecture, though the grounds for such supposition are admittedly strong. Mr. Dewar's note in *The Garden* states that Mr. Boyd first considered the parents to have been *Saxifraga Burseriana* and *S. Rocheliana*, both white-flowered specimens. When the plant first flowered at Kew Mr. Dewar wrote to Mr. Boyd suggesting the influence of *S. aretioides* in the hybrid, and Mr. Boyd, remembering the existence of the last-named species in his garden at Cherry Trees, concurred in Mr. Dewar's views. The question might probably be solved by attempting to reproduce a hybrid identical with *S. Boydii* by crossing the above-named species; indeed, I have a seedling that may assist to this end. In Mr. Dewar's article in *The Garden* he refers to *S. Boydii* alba as "undoubtedly of the same parentage, with more of the *Burseriana* blood than of *S. aretioides*, which shows itself in the number of flowers and denser rosettes." Now there is not the slightest

evidence in *S. Boydii* alba, either in the growth of the plant or in its flowering, of any influence of *S. aretioides*, and I much incline to the opinion that the parentage originally given by Mr. Boyd as that of the yellow *S. Boydii*, viz., *S. Burseriana* and *S. Rocheliana*, was in reality that of *S. Boydii* alba. In the flower truss and in the greater freedom of growth there is abundant evidence in support of such a theory, and, again, the much larger rosettes and the quickly-spreading habit support the same view. *Boydii* alba is, however, not a good name for the plant which bears it, and one might reasonably expect just a white-flowered *Boydii* from the name, but in reality it is a totally distinct plant from *S. Boydii*. In the inflorescence the plant more nearly resembles the Italian *S. marginata*, and this likeness directs one at once to *S. Rocheliana*, the very early flowering of *S. Boydii* alba bearing evidence of the influence of the other parent, viz., *S. Burseriana*. *S. aretioides* *primulina* has also been suggested as one of the parents of *S. Boydii*, but I think it has been established beyond dispute that the late Mr. Boyd was not then in possession of this rare and beautiful variety. Whatever the parentage of the two plants in question may be, they have played their part in creating a desire for more. E. H. Jenkins, Hampton Hill.

SOCIETIES.

NATIONAL CHRYSANTHEMUM

ANNUAL MEETING.

FEBRUARY 4.—The annual general meeting of the members of the above society was held on this date in Carr's Restaurant, 264, Strand, W.C. The President, Charles E. Shea, Esq., occupied the chair. We publish the following

EXTRACTS FROM THE REPORT.

The names of 60 new members have been added to the roll during 1906.

The customary three exhibitions were held at the Crystal Palace in 1906. The outstanding feature of the shows was the increased attention given to single and decorative blooms, which fully justified the committee's action in extending the classes for these varieties in the schedule.

The exhibition of market Chrysanthemums held at the Foreign Flower Market, Covent Garden, W.C., on Wednesday, December 12, by permission of His Grace the Duke of Bedford, K.G., was very successful.

The shows for 1907 have been fixed for Wednesday and Thursday, October 2 and 3; Wednesday, Thursday and Friday, November 6, 7, and 8; and Wednesday and Thursday, December 4 and 5. Negotiations are now taking place with the Crystal Palace Company for the holding of these shows there. The Market Show for 1907 will be held on Wednesday, December 11.

One hundred and eighty-five new varieties were exhibited at various exhibitions, but the committee only felt themselves justified in granting First Class Certificates in 34 cases.

On the recommendation of the Publication Sub-committee, your Executive Committee resolved to issue a Year Book early in 1907. This Year Book will contain articles from the pens of leading English, American, and Australian authorities on Chrysanthemum culture, numerous illustrations and statistical information of the highest value to exhibitors and growers, besides a series of critical and literary contributions on many subjects of interest connected with the Chrysanthemum. Mr. C. Harman Payne and Mr. Chas. H. Curtis have acted as hon. editors of this publication, which is now in the press. Copies of the book will be forwarded free to all members of the society as soon as they are received from the printers.

Your committee have taken the necessary steps to institute a "Dean Memorial Medal." The cost of the die has been defrayed by voluntary contributions, and a balance is still in hand to pay for the medals that may be awarded.

A new degree of membership is suggested, viz.: "Corresponding Member," and it is proposed that this degree of membership should be conferred on such persons as have a special knowledge of the Chrysanthemum, and are thus able to give the society the benefit of their knowledge if, and whenever, applied to.

FINANCE.

The balance-sheet shows total receipts from all sources of £608 16s. 10d., including £147 5s. received as members' subscriptions for 1906, and the grants from the Crystal Palace Company. On the other side of the accounts, prize-money was responsible for the expenditure of £122 10s., printing £79 18s., medals and engraving £86 17s. 2d., judges' fees and luncheons £36 5s., salaries £125, &c.

The report and balance-sheet were passed without comment, save the introductory speech of the proposer, Mr. Thos. Bevan, who announced that the balance-sheet was further brightened owing to the Crystal Palace Company having, since the report was published, paid nearly the whole of the money promised in 1906, and this has enabled all the prize-winners to be paid in full. They had agreed with the Crystal Palace Company to hold their exhibitions for 1907 at Norwood, and for this they were to receive £200 from the Palace authorities. A small saving would have to be made in the schedule.

The President remarked that, all things considered, the report and balance-sheet were satisfactory, but there was an absence of progress recorded, and he asked why. As a comparison, he instanced the progress the Rose Society is making, although the Rose has no greater claims over the Chrysanthemum. He was a firm believer in the need for the society publishing literature on the subject of the Chrysanthemum, for the *Year Book* of the sister society laid the foundation of much of its recent progress; indeed, from a single copy displayed on the speaker's own table, 15 persons had been induced to join the N.R.S. Competitive exhibitions were, however, the life of such societies as theirs, and he desired to see the society cater more and more for the small exhibitor. In some of the small classes of the Rose Society from 30 to 35 exhibitors were found, and in all likelihood these small classes would be further divided to attract a still further number of smaller growers.

AMENDED RULES.

The rules of the society were presented to the meeting in an amended form, and were carried *en bloc* without discussion. The principal alterations are in defining the duties of the respective officers and committees.

On the proposition of Mr. Bevan, Chas. E. Shea, Esq., was again elected president of the society. Mr. John Green was elected treasurer in the place of the late Mr. Taylor, and a vote of sympathy was passed with the family of the late treasurer, to be forwarded in the name of the meeting. Other officers were elected as follows:—Mr. Thos. Bevan, chairman of committees; Mr. E. H. Hawes, vice-chairman, in the place of Mr. J. H. Witty; Mr. C. Harman Payne, hon. foreign corresponding secretary; and Mr. Richard A. Witty, general secretary. The following gentlemen were appointed to fill vacancies on the committees:—Messrs. W. O. Hieble, Geo. Heming, Geo. Cassidy, A. Hemmley and J. H. Witty.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

JANUARY 24.—*Present:* E. Ashworth, Esq. (in the chair), and Messrs. Sander, Warburton, Rogers, Shill, Keeling, Upjohn, Cypher Ward, Thorp, Cowan, P. Smith, Williamson, Parker, and P. Weathers (hon. sec.).

Ten degrees of frost did not prevent some of the more enthusiastic members sending exhibits.

A. WARBURTON, Esq., Haslingden, obtained a Silver Medal for a group, and Awards of Merit for *Cypripedium* × Miss Louisa Fowler and *C. x Traceyanum*. *C. x aureum virginalis* was also shown from the same collection and the previous award of a First-Class Certificate confirmed.

Messrs. J. CYPHER & SONS, Cheltenham, staged a really good group, which gained a Silver-Gilt Medal. A pretty collection of the white varieties of *Laelia anceps* was included in this group.

Messrs. CHARLESWORTH & Co., Bradford, exhibited their new and beautiful hybrid, *Brassocattleya* × Queen Alexandra, which obtained a First-Class Certificate, and the same firm received an Award of Merit for *Cypripedium* × Mrs. Fred Hardy "magnificum."

Messrs. SANDER & SON, St. Albans, received an Award of Merit for *Saccolabium bellinum giganteum*.

G. F. MOORE, Esq., Bourton-on-the-Water, exhibited *Cypripedium* × G. F. Moore, a hybrid between *C. x Sallieri* × *C. Mrs. Mostyn*, to which an Award of Merit was granted.

Messrs. KEELING & SONS, Bingley, Yorks., staged a small group of Orchids. P. W.

CARDIFF & COUNTY HORTICULTURAL.

JANUARY 29.—This progressive society held its annual meeting on the above date, under the presidency of Mr. Vernon Hill, J.P. After payment of all liabilities a credit balance of £204 is carried forward. The report and balance sheet were adopted, and the date of the next show fixed for July 24 and 25, at which a challenge cup, value ten guineas, will be offered for herbaceous flowers. Sweet Peas, a strong feature in last year's show, will be strengthened by an audit class, for which the National Sweet Pea Society are offering a gold and silver medal. Sir John T. Dillwyn Llewelyn, Bart., was appointed president for the ensuing year, and the other officers were also appointed. The retiring members of the executive committee were re-elected.

Obituary.

JOHN WALLIS.—We have received news of the death of this well-known and respected gardener at the age of 70 years, which occurred on the 4th inst., at Woore, near Newcastle-under-Lyme. Considerations of time and space will only permit us, for the moment, to express our regret upon this sudden termination of a very short illness.

ENQUIRIES AND REPLIES.

HOUSE FOR CARNATIONS.—Will some readers please give their views on the best kind of house for Carnations growing? I am thinking of building a span-roofed structure with a division, one part to be occupied with Souvenir de la Malmaison, and the other with tree Carnations. What are the most suitable dimensions? What would be the approximate cost per foot run of such a house? I do not want an expensive house, but hope to get efficiency with economy. *Enchantress.*

VALVE FOR USE IN POND.—In reply to *Aquatic*, see p. 79, a simple and effective valve for use in the pond can be made as follows: Procure two circular iron rims about 2 inches wide and three-eighths of an inch thick, made to bolt tightly together. Between the two iron rims should be placed a stout leather or rubber washer of such a size that there is about an inch of material on the inner edge of the iron all round, to form a seat for the ball valve, which should be made of stone properly turned and provided with an iron ring. There should be a dip in the pond bottom at the point where the valve is to be built in, as then all that is necessary to stop the outlet is to drop in the stone ball anywhere within a foot or two of the outlet when it will immediately roll into position. By this means the pond can be either emptied or lowered to any desired point. The outlet to valve that I have in mind was, as nearly as I recollect, 6 inches in diameter and the stone ball about 9 inches in diameter. It was made and supplied by Messrs. Pulham & Sons. W. C., Cransford.

ANSWERS TO CORRESPONDENTS.

* * * The Editor will be glad to receive, for consideration, large photographs of horticultural subjects, suitable for forming Supplementary Illustrations to this Journal.

ACACIA JULIBRISSIN: *Lexden*. The correct name of this plant is Albizzia Julibrissin. It is a native of the Orient and is commonly known under the name of "Pink Siris." You need not be alarmed at your young plants losing their leaves, as this species is deciduous during the winter months, and it would be advisable that they should be placed in cold frames in preference to a greenhouse during the next few months. The plant is of very easy culture, thriving in almost any sort of soil, and is able to withstand 10 or 12° of frost with impunity when it has become old and woody. The young plants are more tender and require protection until a few years old. The best plan to succeed with this species in your locality is to grow the plants on in pots for two years, and afterwards plant them out at the foot of a wall facing to the south, affording some protection during severe weather.

BEGONIAS: *F. J. R.* You have not sent specimens, but we suspect that the rusty appearance you complain of is caused by mites. Immerse the plants in Tobacco-water.

CHAMÆROPS: *J. C.* You may certainly let the Palm flower, and set fruits if it will. The result will be nothing worse than a slight and temporary hindrance to growth.

CLUB IN CABBAGES: *T. W. B.* Some cultivators, when planting out young Cabbages, take the precaution to "puddle" the roots in a mixture of soot, lime, and earth, made with water to the consistency of paint. We expect you refer to this practice, which is to be recommended, not only as affording some protection against fungus, but in helping the plants to withstand drought for a time whilst making new roots.

GRUB IN PEAR SHOOT: *J. C.* The grub is that of the wood leopard moth, *Zeuzera æsculi* (fig. 44), described in the *Gardeners' Chronicle*, p. 246, April 11, 1846. The larva is somewhat similar to that of the goat-moth, but it is much smaller, being only 1½ inch long, fleshy, and of a yellow colour. The larvæ live in the trunks of various trees, including Apple, Pear, Horsechestnut, &c., and it derives its specific name from the last-named. The moths are hatched about the

FIG. 44.—THE WOOD LEOPARD MOTH: LARVA, PUPA, AND EGGS.

end of June, and are found until the end of August. Many of the eggs are laid in July and the larvæ issue from them so as to cast their skin in September, and arrive at maturity the following June. The best plan to kill the larva is to pour a few drops of bisulphide of carbon in their burrows; they may also be removed by means of a piece of hooked wire, or killed by pushing a stiff rod of wire or iron in their holes.

NAMES OF FLOWERS, FRUITS AND PLANTS.—We are anxious to oblige correspondents as far as we consistently can, but they must bear in mind that it is no part of our duty to our subscribers to name either flowers or fruits. Such work entails considerable outlay, both of time and money, and cannot be allowed to disorganise the preparations for the weekly issue, or to encroach upon time required for the conduct of the paper. Correspondents should never send more than six plants or fruits at one time: they should be very careful to pack and label them properly, to give every information as to the county the fruits are grown in, and to send ripe, or nearly ripe, specimens which show the character of the variety. By neglecting these precautions correspondents add greatly to our labour, and run the risk of delay and incorrect determinations. Correspondents not answered in one issue are requested to be so good as to consult the following numbers. FRUITS: *Daniel Bros.* Cullen.—*J. C. W. & Son.* Orange Goff.

PLANTS: *F. E. S., Oxon.* *Cypripedium* insigne of the good original type. It is sometimes called variety sylhetense in gardens.—*C. E. F.* *Epidendrum angustifolium*.—*F. P. O.* 1, *Adiantum trapeziforme*; 2, *Adiantum formosum*; 3, *Polypodium aureum*; 4, *Pteris cretica*; 5, *Selaginella viticulosa*.—*J. PLANTS SUITABLE FOR A JAPANESE GARDEN ON THE PACIFIC COAST OF N. AMERICA: *J. T.* As the maximum and minimum temperatures given are 80° max. and 60° min., it should

be possible to grow almost any plant that is indigenous to mid and southern Japan. The Pacific or western slope of the Rockies affords an almost ideal climate, which, and especially in the centre and south, affords what is needful, namely, an abundant rainfall, which is tempered by south-westerly winds that blow from the ocean. The whole family of Bamboos should thrive there in the greatest luxuriance, as they do along the Riviera, where they may be seen in the finest possible condition not far away from the Mediterranean. The best of those which do well even in this country are *Arundinaria fastuosa*, *A. Falconeri*, *A. anceps*, *A. nitida*; *Bambusa palmata*, *B. tessellata*, *B. japonica*, *B. Fortunei*, *Phyllostachys aurea*, *P. nigra*, *P. mitis*, *P. viridi-glaucescens*, *P. Quiloi*, *P. Castillonis*, *P. Henonis*, and many others, but those given are in this country well-proven kinds. *Cycas revoluta*, which forms a very fine feature in many Japanese gardens, should be quite at home. So also would the following Palms:—*Chamaerops Fortunei*, *Rhapis humilis*, *R. flabelliformis*, *Livistonia chinensis*, and *Cocos flexuosa*, as well as *C. Jatai* (syn. *C. australis*). *Cocos flexuosa* delights in semi-shade, whilst *C. australis* needs the full sun, and thrives amazingly in a dry, arid spot. That well-known decorative plant, *Aspidistra lurida variegata*, would do well for a groundwork. Note also should be made of the whole of the *Eulalia* genus for producing early effect and removal later on. For groundwork also the whole race of *Funkias* are most useful, thriving in moist, shaded spots. For the open, *Fatsia* (*Aralia japonica*) and its variegated form are both effective. Of the Japanese *Coniferae* there is a host of good things, too numerous to specialise, but these will be found amongst the *Retinospora*, the *Thuja*, the *Pinus*, and the *Picea* genera. These are most valuable in any garden, not only the types in their dense green shades, but in the golden and glaucous variations which many have assumed. The deciduous Larch (*Larix leptolepis*) is a great favourite with the Japanese, it being most amenable to tortuous twistings and contortions, whilst it is most beautiful when naturally grown, especially in the bud stage and early formation of the leaf, by reason of its colour. Almost every Japanese garden contains one or more forms of *Rhodea japonica*. Japanese Maples should be included, and they will thrive in this country very well, but in the locality under consideration they ought to do even better and the colours be intensified. Of flowering plants it may be said the choice is quite bewildering. Of Aquatics the *Nelumbium speciosum* should certainly be tried, and the *Sagittaria japonica*. Of semi-aquatic plants, *Iris Kaempferi* only requires to be named. Of climbing plants there are many, the *Wistaria* and the *Clematis* being prominent. Ferns in variety for shady positions should be noted: of these there is a wide choice. The flowering Cherries of Japan are notable features, being greatly appreciated there. *Azalea mollis* is quite indispensable, whilst the Japanese *Magnolias* are a host in themselves, such, for instance, as *M. conspicua*, *M. stellata*, *M. hypoleuca*, and *M. Watsoni*. For moist spots the *Magnolias* and the *Hydrangeas* should be chosen. In the more favoured positions the Japanese Orchids ought certainly to have a place. *Camellias* should thrive well also, and likewise the *Pæonies*: these are typical Japanese plants. Fruit-bearing plants should not be omitted in such a climate. Of these the *Citrus* in variety claims notice for both edible and decorative purposes. Of *Diospyros Kaki* and of *Prunus* there are several notable varieties that are useful.

VIOLET ROOTS: *C. S.* There is no fungus disease in the Violets. The blanched roots are caused by some physical or chemical cause, as there is no fungus there.

PRESDALES.

CHARMINGLY situated on high ground amidst sylvan and floral beauties, and within a short distance of the old and somewhat picturesque town of Ware, is Presdales, the Hertfordshire home of Albert G. Sandeman, Esq. It is approached from two separate points from the Ware to Hertford Road past two commodious lodges, one at each entrance. The house—a view of which was given in the *Gardeners' Chronicle* for September 27, 1902, p. 229—is a modern built and picturesque edifice in the Elizabethan style, and commands pleasant views from the terrace of near and distant scenery, including beautifully wooded hills and green dales. The walls, consisting of dressed stone, are clothed on the south front with flourishing trees of *Magnolia grandiflora*, *Ampelopsis Veitchii*, closely-trimmed Ivies, Jasmines, Roses, &c. From the terrace mentioned, two separate flights of stone steps lead down to the principal flower garden, Rose border, and ornamental water. The flower beds—including an isolated, oblong bed, having a background of the white-flowered Japanese *Anemone* (Honorine Jobert), with scarlet-flowered tuberous-rooted *Begonias* in front, and a broad edging of *Centaurea candidissima*—were, at the time of my visit (September 1), gay with a pleasing combination of colour, and which, viewed in con-

nection with an extensive area of well-kept sward and the pleasing and varied surroundings, made a picture of much beauty, and one which it would be hard to excel in the county of Herts. The fountain occupies a central position in the flower-garden proper, and was surrounded by a large band of well-flowered white *Marguerites*. The beds were filled similarly in pairs, some with the silver-leaved *Pelargonium Flower of Spring*, and edged with a band of *Golden Fleece Fuchsia*, others having centres of pink-flowered *Pelargonium Christine*, with a band of the velvety dark-foliaged *Coleus Verschaffeltii* and an outer edging of blue *Lobelia* (*pumila magnifica*). Two similarly shaped beds had centres of light-flowered *Fuchsias*, with a surrounding broad band of *Henri Jacoby Pelargonium*, and they were edged with a small silver-leaved *Pelargonium* of the *Princess Henry* of *Battenberg* type. Small beds filled entirely with the bronzed-leaved *Pelargonium Her Majesty* contrasted effectively with the mixed beds. Two round beds on the terrace planted with *Phoenix Palms* in their centres, and filled with finely-flowered yellow *Antirrhinums*, and edged with mauve-coloured *Ageratum*, were objects of great beauty, as were also other beds close by filled with *Henri Jacoby* and double white *Pelargoniums*, and edged with blue *Lobelia*. Large vases on the terraces were filled with white *Marguerites* and edged with *Madame Crousse Ivy-leaved Pelargoniums*, the flowering shoots of the latter, with their large trusses of satiny pink-coloured flowers, intermixing with the *Marguerites*, and depending gracefully over the edges of the vases. Several large vases occupied positions on either side of the principal walks in the kitchen garden, and these were filled with *Marguerites* and *Heliotropes*; smaller vases were also filled with *Marguerites*, but edged with *Souvenir de Charles Turner Pelargoniums*, bearing large trusses of cerise flowers that hung effectively over the sides of the receptacles. Ornamental tubs, standing in close proximity to the front entrance of the mansion, were filled with *Henri Jacoby* and *Jeanne d'Arc Ivy-leaved Pelargoniums*, the beautiful white flowers of the latter, suffused with light lavender, showing in contrast to the large crimson trusses of the former.

Nature has done much for Presdales, and the landscape gardener, Marnock, made the most of the natural beauty of the place. But the ground space immediately in front of the mansion and adjoining the lower flower garden was subsequently extended by Mr. Sandeman, as hitherto the area of the ornamental grounds in that direction was considered to be too confined, and therefore did not show to advantage the picturesque pile of buildings in the background. Many fine trees, including a handsome young specimen of *Cedrus atlantica*, were observed in the grounds during the writer's hurried visit.

THE KITCHEN GARDENS

are about 3 acres in extent, two of which are enclosed by walls, which are well furnished with choice and well-trained fruit trees. The kitchen garden contained crops of seasonable vegetables, including good breadths of *Veitch's Autumn Giant Cauliflower*, and several varieties of *Broccoli*, *Cabbage*, *Brussels Sprouts*, *Winter Greens*. Several rows of *Celery*, planted at from 4 to 5 feet apart, were observed, the ridges being occupied with rows of *Lettuce* in various stages of development, some close, solid heads being ready for use. Good beds of *Onions* were also noted, the bulbs being of a large size, firm, and well ripened, ready for harvesting. *Lettuce* and

Endive were observed growing in wide borders in front of walls having a south aspect. A portion of these plants were intended for lifting towards the end of October for transplanting into cold pits, from which frost and heavy rains can be excluded, for yielding supplies during the winter and early spring months. Every provision is made by Mr. F. Noyce, the gardener, to meet the requirements of a large establishment in the matters of high-class vegetables and fruits in all seasons. A 2-acre field attached to the gardens was largely devoted to the production of *Potatoes*, several long rows of *Broccoli* (*Veitch's Model*), *Brussels Sprouts*, &c., being grown in the remaining portion. Of the *Potatoes*, Mr. Noyce spoke highly of *Sutton's May Queen* as a reliable variety for yielding early supplies of good quality tubers, and the heaviest croppers with him are *Carter's Snowball*, *Windsor Castle*, *Sir John Llewellyn*, *Ninetyfold*, and *Sutton's Satisfaction*.

FRUIT TREES.

Apples are grown on either side of the wide gravel walks in the kitchen gardens. The trees (of leading varieties) are good-sized specimens, and were carrying heavy crops of fine-quality fruit; the branches had been subjected to judicious annual thinning and shortening of the current year's growths. Plums of the varieties *Jefferson's*, *Washington*, *Kirk's*, *Coe's Golden Drop*, *Guthrie's Gage*, &c., were fairly plentiful on trees growing against walls facing east and west, as were also *Morello Cherries* on trees trained on north walls; the crops of sweet *Cherries* had been plentiful on trees occupying a wall facing westward, the varieties grown being *May Duke*, *Black Eagle*, *Frogmore*, *Bigarreau*, *Governor Wood*, *White Heart*, &c.

The finest, healthiest, and best managed lot of *Peach* and *Nectarine* trees that I have seen for several years past were noticed. The trees were furnished from the ground line with fruitful, well-trained branches and large healthy foliage, and had borne good crops of fruit. Some of the trees, such as *Violette Hâtive* and *Sea Eagle*, were, at the time of my visit, ripening their fruits. The ground, for a space of about 3 feet from the wall, was heavily mulched with half-decayed manure, and liberal waterings afforded during the summer months had washed the soluble particles of the manure down to the roots with most satisfactory results. Among the *Nectarines* grown at Presdales are *Rivers' Early*, *Pineapple*, and *Dryden*.

A wall having a south or south-west aspect furnished a picture of healthy, well-trained, heavily-cropped, cordon *Pear* trees, the sight of which in itself well repaid a visit to Presdales. The trees, 61 in number, are trained obliquely, and they were all carrying heavy crops of large, handsome, well-developed fruits of the respective varieties. These consisted of *Durondeau*, *Fertility*, *Souvenir du Congrès*, *Emile d'Heyst*, *Duchess d'Angoulême*, *Beurré Bachelier*, *Beurré d'Anjou*, *Doyenné du Comice*, *General Todleben*, *Olivier de Serres*, *Princess*, *Pitmaston Duchess*, and *Nouvelle Fulvie*.

PLANT AND FRUIT HOUSES.

The glasshouses are conveniently situated at the north end of the kitchen garden, and consist of plant, stove, *Carnation* house, *Marguerite* house, *Fernery*, greenhouse, and *Palm* house, two *vineries*, *Melon* house, in three divisions, orchard house, besides numerous pits and frames. A nice lot of foliage and flowering plants, including brightly-coloured *Dracenas* and *Codiaeums* (*Crotons*) in variety, were

observed in the stove, all being, like the Ferns and all the other plants cultivated under glass at Presdales, of a decorative character for use in the residence. A good batch of Malmaison and perpetual flowering Carnations were observed in a house devoted to their culture, and in a span-frame close by were a quantity of flourishing young layered plants nearly ready for potting. The old plants had been turned out of their pots, and they were planted in about 6 inches deep of lightish mould and the shoots layered therein, the soil having been first surfaced with sand.

In the vineries were hanging bunches of Madresfield Court, Black Alicante, and Mrs. Pince's Black Muscat, the bunches of the latter being larger and better coloured than is generally seen in this fine late Grape.

Melons were flourishing on the single-stem system of training in one house, the fruits of Royal Jubilee, Earl's Favourite, and Lockinge Hero, being good specimens of skilful culture. Tomatos growing in narrow boxes in one of the houses and trained to a trellis a short way up the roof were bearing heavy crops of large, even-sized fruits, the varieties being Sutton's Perfection, Sutton's Al, and Polegate. The fruits of the latter variety are large, but irregular in shape. Other plants of the same varieties, with the addition of Up-to-Date, were planted in the open and trained singly and obliquely against the front wall of the same house, and bearing heavier crops of equally fine fruit than the plants growing inside. In both cases the lateral growths were kept persistently pinched and the foliage shortened back. By training the single-stemmed plants obliquely, a greater length of stem was obtained than could otherwise be secured, and the check thus given to the flow of sap ensured a better and more regular development of flower-trusses and a better setting of fruits than would otherwise be obtained.

Growing mostly in 10-inch pots were noticed several hundred plants of Chrysanthemums, not intended for large exhibition blooms, but for yielding a plentiful supply of cut flowers during the winter months. Other winter-flowering subjects were also observed growing in borders, and, like the Chrysanthemums, in pots, standing on the gravel walks and such-like places, ready for removing to the glasshouses in due time. Well-established plants of Marie Louise and Princess of Wales Violets, growing in borders, were ready for transferring to pits and frames occupying sunny aspects towards the end of September or early in October.

The young gardeners are comfortably housed and well cared for, as, indeed, are all the employees on the Presdales estate.

Evidences of cultural skill, good management, and perfect order were noticeable in every department of this beautiful estate, and proved the capabilities of the gardener, Mr. Noyce, and the efficiency of his staff. *H. W. Ward.*

NEW OR NOTEWORTHY PLANTS.

WOODWARDIA PARADOXA, SP. NOV.*

A SPECIMEN of a new species of Woodwardia has been received at Kew from Mr. F. W. Moore, A.L.S., of Glasnevin, who states that it is an evergreen Fern from a small island off Vancouver Island. Its fronds are narrower than those of the common *W. radicans*, J. E. Smith, to which it bears much resemblance in the cutting of its pinnules, but differs in having the veinlets perfectly free from the sorus to the margin as in *W. virginica*, J. E. Smith. The geographical distribution of these two last-mentioned species is very different. *W. radicans* encircles the northern hemisphere, and has for its northern limits Spain, Italy, North India, South China, and California, while *W. virginica* is confined to the eastern half of the North American continent and Bermuda, extending northwards to Nova Scotia and Ontario.

The oblong-lanceolate acuminate frond is 3 feet long and 9 inches wide at the middle, and has the lower pinnæ conspicuously reduced. The lanceolate pinnæ, are about 6 inches long and 1½ inch wide, and spring from the rachis at an angle of about 45°, the lobes are nearly 1 inch long and ¼-inch wide, serrate at the margin, and bearing about six sori on each side of the midrib. The whole frond is glabrous and destitute of scales. Its rootstock I have not seen: *C. H. Wright, Kew.*

THE WOBURN WASH.

As many fruit-growers will now be applying a winter wash to their trees, I should like to make known an important improvement which has been effected in the Woburn wash, although further investigation may still be necessary to perfect this improvement. The original wash consisted of a combination of caustic alkali with paraffin emulsion, and contained two per cent. of caustic soda, six per cent. of paraffin, and half per cent. of soft soap. The paraffin was first emulsified with half its volume of water, in which the soap had previously been dissolved, and the emulsion thus obtained was then added to the rest of the water with the soda dissolved in it. The only difficulty in using the wash lay in the fact that the soft soap was converted by the soda into hard soap, which, with the paraffin (still partially emulsified), rose to the surface as a scum, and rendered constant agitation necessary. Judging from the excellent results obtained, and the absence of any injury to the trees when the wash was used, either with a tank or a knapsack machine, this difficulty was not very serious; yet it certainly was a drawback, and, as indicated in our report, the search for some suitable emulsifier other than soap was very desirable.

Recent work in America has shown that lime will emulsify paraffin with water. This has formed the starting point of a somewhat long series of investigations, the conclusion of which is that, although lime cannot be used very satisfactorily as a substitute for soap in the Woburn wash, there are other somewhat analogous substances which can be so used, and which give a wash answering all requirements. The substances investigated include various hydroxides

(lime is an hydroxide of calcium), carbonates and basic sulphates. The two which I will mention now—though they may not eventually prove quite the best—are the basic sulphates of iron and copper.

Soda emulsions containing these may be prepared as follows:—Take sulphate of iron (copperas) or sulphate of copper (blm vitriol), 1½ lb.; quicklime, 6 oz.; paraffin, 5 pints; caustic soda, 2 lb.; water, 9½ gallons. Dissolve the sulphate of iron or copper in the water by suspending it in a bag of sacking overnight; at the same time put the lime in a jar with enough water to not quite cover it. Next day, when the sulphate is dissolved and the lime slaked, add a little more water to the latter, to make it into a milk, and pour it into the sulphate solution. Add the paraffin and churn the mixture with a garden syringe. One or two strokes of the syringe are sufficient to produce a perfect emulsion. The soda may then be added and the whole mixed well together. If the soda is in the powdered form, it may be added while solid to the water; if it is in large lumps, it should be dissolved separately in a portion of the water reserved for that purpose.

It is possible, in the case of the iron emulsion, to dispense with the lime, substituting for it another ½ lb. of caustic soda (to be added before the paraffin is put in); but the emulsion thus obtained is not so fine as that produced by the use of lime. With the copper emulsion such a substitution is not possible. The iron emulsion is considerably finer in character than the copper one, but the latter possesses the advantage of containing a fungicide of recognised value: it contains, in fact, normal Bordeaux mixture, and is a combined insecticide, fungicide, and destroyer of moss and lichen. Either emulsion will remain for hours without any appreciable rising to the surface, and, even when such rising has occurred, the slightest agitation will suffice to restore uniformity to the mixture. We have not yet found any indication of de-emulsification—i.e., of the separation of the paraffin from the emulsion.

The proportions of the constituents may be modified if desired. The copper sulphate may be doubled in amount, if a more energetic fungicidal action is required, but the lime used should be increased in a corresponding degree. The paraffin may be increased or diminished without affecting the emulsification, and the proportion of soda also may be varied, but 2 per cent. is the smallest amount which will ensure the removal of moss, &c., whilst more than 2 per cent. gives so caustic a liquid that danger is involved to the workmen using it. In the *Journal of Horticulture* for January 31 the proportions given for these washes differed slightly from those given here; the present recipes represent the results of further work on the subject.

The chemical and physical problems presented by these emulsions appear to be very interesting, but at present very obscure. The mere fact, however, that emulsions can be made so easily and so perfectly with a large number of precipitated solids, is a matter of great practical importance, as it will give fruit growers and gardeners a new weapon of attack for pests in general. Only one of the several curious points connected with these emulsions need be mentioned—namely, that the chemical character of the precipitate in the case of the iron and copper washes—and, consequently, the character of the emulsion—is affected by the nature of the paraffin used. The best results, so far, have been obtained with a solar distillate supplied by the Hope Chemical Works, Hackney Wick. This costs 4½d. the gallon, and is not reckoned as an inflammable for transit purposes. *Spencer Pickering, Woburn Experimental Fruit Farm.*

* WOODWARDIA PARADOXA, C. H. Wright, sp. nov.: *W. radicans*, J. E. Sm., simulans, venulis autem inter soros marginesque non anastomosantibus recedit. Frondes oblongo, lanceolati, acuminati, circa 90cm. alti, 22cm. lati, glabrescenti, perennēs. Pinnæ lanceolatae, 15cm. longae, 3-5cm. latae, erecto-patentes; lobi oblongi, leviter falcati, fere 2-5cm. longi, 5mm. lati, acute serrati. Sori circa 6 subtus utroque latere positi, elliptici.—Small island near Vancouver Island.

TREES AND SHRUBS.

TORREYA CALIFORNICA.

THIS Taxaceous tree, sometimes called *T. Myristica*, and by some placed in the genus *Tumion*, does not do well, as a rule, in this country, though probably in the south-west and in Ireland it might be cultivated as an ornamental evergreen. It is a native of California, where it occasionally reaches a height of 100 feet. It was introduced to this country by William Lobb for Messrs. Veitch. Up to this time we have not noticed much variation in individual specimens, nor are any mentioned in the Kew Hand-list, and Mr. Bean informs us that variation has not been noticed in the specimens grown at Kew.

We were in consequence the more surprised at receiving lately from Messrs. Croux et Fils,

distinguished from all the rest by its closely set, dark green, arching, relatively short foliage, which gives a plumose appearance to the branches.

The branches are ascending, bark of old shoots deep purple, that of the herbaceous shoots green. Buds ovoid compressed; scales conduplicate coriaceous, suborbicular reddish-brown glabrous. Leaves densely arranged, spreading horizontally 25 to 30 millimetres long, deep-green, much curved from base to point, linear oblong, spine-tipped convex on the upper surface.

2. Branches spreading dense, bark of old shoots reddish, of new shoots green. Buds ovoid acute compressed scales coriaceous deltoid-ovoid acute chestnut brown, with a narrow white margin. Leaves spreading or slightly ascending, 5 centimetres long 4 millimetres broad, straight, linear, acute, spine-tipped, deep green above, or in some leaves yellow, with a

This is described as of more regular habit than No. 3, with green foliage and more dense (etouffé) than in No. 2.

5. Branches ascending, lax; bark of the young shoots green, becoming reddish-brown when older. Buds ovoid, compressed, scales coriaceous suborbicular, pale brown. Leaves ascending, 25 to 40 millimetres long, linear, straight, 5 millimetres broad, shortly spine-tipped, spine translucent.

This variety is described as of spreading habit, shorter than broad.

6. Branches loose, widely spreading, buds oblong, acute, with oblong acute coriaceous chestnut-brown scales. Bark of the young shoots reddish-purple, with raised cushions (pulvini), older shoots dull brown. Leaves spreading 25 to 30 millimetres long, 2 to 3 millimetres broad, falcate, linear-acute, shortly petiolate, deep green above, with a broad central midrib between two whitish bands on the

FIG. 45.—CYPRIPEDIUMS IN THE COLLECTION OF DREWETT O. DREWETT, ESQ.

(For text see page 100.)

of Val d'Aulnay, Chatenay (Seine), some excellent cut specimens from seedlings, showing a considerable amount of variation in the habit of the tree, the direction of the branches, the colour of the herbaceous shoots, the dense, or relatively loose, disposition of the leaves, their spreading or ascending direction, their size and degree of curvature, and other points. In certain respects some of these forms resemble the species of *Cephalotaxus*, but these are usually of a paler green, and have the midrib prominent in the form of a central ridge on the upper surface, whereas in all the specimens of *Torreya* the upper surface of the leaf is convex or without any central ridge.

We give some notes on the specimens submitted as under number:—

No. 1. is stated by Messrs. Croux to be of regular habit, twice as high as broad, with regular verticils of five or six branches. It commences to grow very late—in June. It is

central green midrib between two white bands beneath, somewhat convex above. This variety is noted as of slender, somewhat loose, habit, three times taller than broad. Foliage irregularly but strongly tinted with yellow.

3. Branches ascending, bark of the old shoots greyish-brown, that of the herbaceous shoots green, flushed with red. Bud ovoid, scales coriaceous, reddish-brown, oblong, acute. Leaves ascending 5 to 7 centimetres long 3 millimetres wide, linear, lanceolate, spine-tipped, slightly convex above. Messrs. Croux describe this as of irregular growth and cultivated by them under the name of *T. Myristica*.

4. Branches ascending, old shoots reddish-brown, with grey lines on either side of the pulvini, young shoots green. Bud ovoid, somewhat compressed, scales broadly ovoid, acute, coriaceous, pale brown. Leaves slightly ascending, linear, 50 to 60 millimetres long, deep green, slightly convex above.

lower surface. This variety, raised from seed like the others, has a distinctly weeping habit.

Four specimens of *Torreya* or *Tumion* have survived from the tertiary period when the genus inhabited the Arctic Circle, and then, spreading southwards, existed for a long time in Europe, whence it has now disappeared (Saporta, *Origine Paléontologique des arbres*, 59, cited in Sargent Silva, vol. 10, 1896). Of existing species one, the type of the genus, inhabits Florida, a second is widely scattered through the forests of Western California, one occurs on the mountains of Central and Southern Japan, and another in Northern China (*T. grandis*).

With these specimens of *Torreya* come branches of a *Pinus* called *P. Malleti*, which is evidently one of the many forms of *P. ponderosa* with very long leaves, and of the true *Abies lasiocarpa*, which is also known as *A. subalpina* and *A. bifolia*.

CYPRIPEDIUMS AT WILLOW WOOD, RIDING MILL-ON-TYNE.

THERE are few collections of Orchids that have existed for a longer period than that at Willow Wood, Riding Mill-on-Tyne, the residence of Mr. Drewett O. Drewett. In early days it was remarkable as a general collection and for the fine hybrids it contained, raised by Mr. Drewett. During later years it has been particularly enriched by *Cypripediums* of the winter-flowering section. As will be seen in our illustration (fig. 45), *C. insigne* is one of Mr. Drewett's chief favourites, and he has brought together one of the finest collections of this most variable species. All the best known kinds are included, as well as many others that are not found in general cultivation. One of the finest among these latter is *C. i.* "Aberdeen," a most beautiful variety, possessing refinement and high quality so often lacking in the large flowers of *C. insigne*. Considerable attention has been devoted to the inter-crossing of the best of the varieties, in the hope that some good varieties may be produced, and there are a great number of young hybrid plants, in various stages of growth. *C. i.* "Grand Monarque" is another beautiful variety that has flowered this season, and it is highly prized by its owner. The plants seen in fig. 45 were carrying more than 500 expanded flowers at the time the photograph was taken, and the whole of the plants displayed excellence of culture. Mr. J. Renwick, the gardener, is an able seconder to Mr. Drewett in his enthusiasm for *C. insigne* and other winter-flowering species and hybrids. *H. J. Chapman.*

KEW NOTES.

THE GREENHOUSE.

SEVERAL early flowering trees and shrubs are already conspicuous in this house (No. 4). The hybrid *Rhododendron præcox* is naturally early-flowering, the blossom often being spoilt by frosts out of doors, but the plants respond readily to a little forcing, and the rosy-purple flowers soon make their appearance. Several large bushes of the double white *Spiræa prunifolia* call for special mention, the long slender growths being well furnished with flowers. *Forsythia suspensa* (syn. *Fortunei*), with its graceful habit, and the more erect growing *F. intermedia* are particularly spring-like in appearance. Another plant with yellow flowers is *Jasminum primulinum*. This proves hardy in some parts of the country, but at Kew requires protection. Only sufficient heat is necessary to keep out frosts; too much heat causes the development of growths instead of flowers.

A few spring-flowering bulbs adorn the side stages. Conspicuous are the Tenby Daffodil (*Narcissus obvallaris*) and *N. Golden Spur*. *Crocus* "Sir Walter Scott" appears to be a good variety for early flowering, the striped flowers being robust and freely produced.

A useful addition to the winter-flowering *Eupatoriums* is *E. vernale*, having white flowers. The Kew Wallflower, *Cheiranthus kewensis*, x, continues to flower throughout the winter in a cool house. Grown on for several years large specimens can be obtained; or rooted from cuttings in early summer useful plants in 5-inch pots may be had with eight or ten racemes of flowers. The two large standard plants of *Sparmannia africana*, for several years past a feature of this house in winter, are as full of flowers as ever.

The side stages in one wing of the house are devoted to hard-wooded plants. The slender growth and greyish-green foliage of *Grevillea thelemanniana* have a pleasing appearance. The drooping red and yellow flowers might at first sight be compared in form to a giant spider. *Olearia ramulosa*, a small-leaved, much branched Australian species, has little, white Daisy-like flowers. A large specimen of

Eriostemon myoporoides, 5 feet in height, planted in one of the beds, is covered with buds, while several have already expanded. The white flowers are slightly tinged with pink. Several other smaller specimens of this species in pots and a good plant of *E. affine*, a species with narrower leaves and starry flowers, deserve attention. Some of the flowers on *Acacia platyptera* have faded, but those on several other species are commencing to make a show. These include *A. obliqua*, *A. Drummondii*, *A. verticillata*, and *A. armata*. Although *Erica mediterranea hybrida* is a hardy plant, it is a useful pot plant for the cool greenhouse, lasting for several months in flower during mid-winter.

ARAUCARIA IMBRICATA.

MATURE trees frequently develop fresh shoots on the trunk around the older or dying branches. These shoots rarely live for any length of time, and it seems that the healthier the original branch the longer these secondary branches become, but they rarely exceed 6 or 7 feet in length. I enclose a photograph of a tree at Pencarrow, Cornwall (see fig. 46), which has thrown out two growths from the bole near to the ground, and instead of growing horizontally, as is usual with these adventitious branches, they have grown erect, having, when seen at a little distance, the appearance of natural seedlings growing close to the parent tree.

FIG. 46.—*ARAUCARIA IMBRICATA*, WITH ERECT BRANCHES FROM THE BASE OF THE TRUNK.

The two central pillars of the house clothed with *Cestrum* (*Habrothamnus*) only require to be seen to prove their value for furnishing unsightly pillars. The species used are *C. elegans* and *C. purpureum*. The former is much the showier plant, the red flowers being bright and very numerous.

Kew has, fortunately, not been visited quite so frequently as usual by fogs this winter, but a brief spell on January 18 and 19 was sufficient to ruin a number of plants and damage many others. *Moschosma riparium*, *Coleus thyrsoides*, and *Tecoma Smithii* suffered severely. Brown patches on the leaves of *Senecio Petaites* look as if they have been scorched, while many of the flower buds have turned brown and will never develop. *D. D.*

The taller growth is just over 12 feet high, and first appeared some 10 years ago. As to its cause, I can only suggest that at some time the tree sustained a blow from the lawn-mower. *A. C. Bartlett.*

THE ALPINE GARDEN.

RANUNCULUS RUTÆFOLIUS.

AMONG the Alpine plants which are not very generally in gardens is this pretty little species of *Ranunculus*, which one would expect was more difficult of cultivation than it really is, although it requires some attention in certain seasons if it is expected to thrive and flower. There is a curious contradiction between the descriptions given in some works regarding the

colour of the flowers of this plant. Thus Nicholson's *Dictionary of Gardening* describes the blooms as yellow, a colour I have not seen in the flowers of this plant. On referring to M. Correvon's excellent little work, *Flora colorée de Poche*, I find that the description there given is white, which is in accordance with my own experience. I should not call them pure white, but there is no doubt that they are a shade from white and not yellow. The centre of the flower is greenish. The inflorescences generally are solitary on a short and somewhat trailing stem, but occasionally two and even three blossoms are borne on the peduncle. The leaves are pinnate, with three-lobed multifid lobes, and from their appearance is derived the specific name of *rutæfolius*. The whole plant is generally from 3 to 6 inches high, more frequently the former than the latter height. It is a native of the high Alpine pastures, where it delights in plenty of moisture during the growing season, but is, of course, in a condition of entire rest in winter. It is impossible to secure these conditions in an ordinary garden, but they may, to some extent, be given, by planting in a thoroughly well-drained situation, and by giving occasional copious supplies of water during spring, summer, and early autumn, placing a few stones about the plants to retain some of the moisture. Under these conditions it may have full exposure to the sun. Although a native of the granite ranges in Dauphiny, Piedmont, Valais, the Grisons, Tyrol, and the Pyrenees, it seems not to dislike lime, and I have grown it on a rockery largely composed of limestone without any apparent harm resulting. It thrives best with me planted only some 6 inches above the ground level of the path and on a flat "pocket," where the rain reaches the roots freely. The soil contained peat with a considerable mixture of sand and grit. The difficulty with this *Ranunculus* is that it increases slowly. It is best propagated from seeds. I have lost it when endeavouring to obtain increase by root cuttings, although its roots from their appearance gave me the opinion that root-cuttings would strike readily. They did not, and the parent was lost in the process. I prefer spring planting in the case of *R. rutæfolius*, and it is desirable to apply an occasional top-dressing of loam, peat, or leaf-mould, and a little sand and grit. This is the more necessary, as the frequent waterings it requires soon expose the "neck" of the plant. This distinct little Crowfoot deserves to be more widely known. S: Arnott, Sunnymead, Dumfries, Scotland.

MUSA BASJOO (SYN. JAPONICA).

This hardy species of Banana was introduced by the firm of Jas. Veitch and Sons, Chelsea, who had the plant growing for several years in the open in their nursery at Coombe. It is a native of the island of Yesso, the most northerly of the larger islands of Japan, and has long been cultivated in that country for its valuable fibre, where it was found by Messrs. Veitch's collector, M. Maries. Our illustration (fig. 47) is from a photograph of a plant growing in the open at Trengwainton, Penzance, Cornwall, the seat of T. Robens Bolitho, Esq. The plant fruited freely in this favoured county, but the fruits require an exceptional summer to ripen in this country, even in the south of England, and plants in the Temperate House at Kew failed to ripen their fruits. It is, however, a handsome foliage plant, and a most valuable subject for sub-tropical bedding, the leaves being almost equal in luxuriance to those of *M. Ensete*. It is very necessary to select a well-sheltered site for such plants as *Musa*, high winds having an extremely disastrous effect on the large, tender leaves. Its propagation is readily effected by means of numerous suckers. The plant is figured in the *Bot. Mag.*, t. 7, 182, and a descriptive note appeared in our issue for December 22, 1900, p. 436.

PLANT NOTES.

RUELLIA PORTELLÆ.

If we except the ubiquitous *Chrysanthemum*, flowering plants are so scarce in December that it seems strange that such a bright winter-flowering plant as this Brazilian introduction should be so little grown. Its requirements are moderate, and its culture easy. Although classed as a stove plant it thrives equally well in an intermediate house where a maximum night temperature of from 50° to 56° Fahr. can be maintained. Cuttings root readily at all seasons; in common with almost all others they should be made with a sharp knife; non-compliance with this precaution is responsible for many failures. They should be short jointed, firmly inserted in small pots of sandy soil, and placed under a hand-light. When rooted they need not be potted off singly, but are best transferred bodily to 5 or 6 inch pots, using a light rich soil and pressing it

FIG. 47.—MUSA BASJOO (SYN. JAPONICA HORT.)
FLOWERING IN THE OPEN AIR.

firmly. During the summer months the shoots should be topped occasionally to induce a compact habit, but as autumn approaches the plants must be allowed to grow naturally or no flowers will be the result. The velvety leaves are so handsome that the plants will occupy a prominent place throughout the year. The rosy-pink flowers are freely produced at the ends of the growths and continue for a long time. Cuttings inserted in August will flower in quite small pots and are most useful for furnishing a jardinière or small vases. Spring struck cuttings will form plants 12 to 18 inches high. A. C. B.

CORYNOSTYLIS HYBANTHUS.

This pretty stove climber, which flowers at the duldest season of the year, is deserving of more general cultivation. It will grow well in a large pot, and better still when planted out, especially if given good soil and provided with

proper drainage. It can be trained up a wall or pillar, but, if space can be afforded, the best place is on the roof, where its flowers are more effective. It is very sensitive to drought, and especially so at the time of flowering, when, if it is allowed to become dry at its roots, the flower buds will drop before they expand. The flowers are produced on racemes, which arise from the axils of the leaves at the apex of the lateral branches. There are four or five racemes on each shoot, each raceme carrying from 12 to 15 flowers, which are snow-white, and with a curious twisted spur. They possess a delicious odour, which pervades the atmosphere of the house during the greater part of the day. The leaves, which are from 4 to 5 inches in length, are minutely serrated, and give further prominence to the white flowers. The plant flowers freely in the Palmhouse at the Royal Botanic Garden, Edinburgh, every year, and is much admired by visitors. It is a valuable subject for gardens, for winter-flowering plants are always acceptable. It is easily propagated by cuttings made of the young growths in the spring. They should be inserted in sandy soil around the side of a small pot. The plant belongs to the order Violaceæ, and is a native of tropical America. It was introduced into cultivation by Mr. Linden, and it is figured in the *Bot. Mag.*, t. 5960. L. B. Stewart, Royal Botanic Garden, Edinburgh.

CALLIPSYCHE MIRABILIS.

This ornamental and extremely curious Peruvian plant belongs to a genus comprising about three species of the *Amaryllidaceæ*. It requires a compost consisting of rich, fibrous loam and leaf-soil, with enough sand to make it thoroughly porous. Afford good drainage, and pot firmly. Copious supplies of water will be required during growth, but when the foliage has signs of decay, it should be gradually withheld, and during the winter months the soil should be kept moderately dry, to prevent the bulbs from excessive shrivelling. The species may be propagated easily by seeds, which should be sown in sandy soil, and the pots placed in a temperature of 70° at night, where they will soon germinate, and when large enough they should be pricked off into pans or pots, and be given a situation well up to the light. The flowers are small and greenish-yellow in colour, with stamens three times the length of the perianth, spreading out on all sides. Remove the plants to a greenhouse temperature when in bloom, for the flowers will be found to last longer there. G. H. Banks, Botanic Garden, Cambridge.

[A fine illustration was given in our volume for 1900, March 31.—Ed.]

DAPHNE INDICA, VARIETIES RUBRA AND ALBA.

In some of the more favoured parts of the country these sweetly-scented Daphnes can be grown against a wall, if afforded slight protection in sharp weather. I have seen out-of-doors plants, covering many feet of wall space, flower annually with great profusion, the air for some distance being filled with the delightful perfume. Those who cannot grow them outside will find them easy to manage in pots, providing they are potted into a good, sandy compost, and the pots are well drained. Stagnant moisture is fatal to the small, fibrous roots, and plants under such conditions will gradually lose their foliage and die. Large specimens can be cultivated in 10-inch pots. All through the summer months the plants should be placed in full sunlight out-of-doors upon a hard base, where they may be syringed two and three times daily. In such a position they will make good growth, and as autumn advances, each point of growth will have set flower buds. Gentle forcing is not harmful to the plants, and a constant supply of flowers can be thus maintained throughout

the winter. Intermixed with other flowers for room decoration, or in making up bouquets, sprays, buttonholes, &c., the flowers add a charm by their sweet perfume.

Propagation is easily effected by cuttings, and also by grafting. Cuttings taken off in July or August should be placed singly in pots, or several together in a 48-size pot, using a very sandy compost. The cuttings must be placed in a cool house, covering the pots with a bell-glass, or kept close in a frame until the cuttings have callused is the best plan, afterwards removing them to a warmer house, still keeping the atmosphere close until the cuttings have rooted well. For the first season and until the plants become thoroughly established, an intermediate temperature is best, as by giving them a genial warmth the young plants establish themselves more quickly.

The "crown" method of grafting is more generally adopted than "side" grafting. *Daphne Laureola* or *Spurge Laurel* is generally used for the stock. This *Spurge Laurel*, which in itself is an attractive evergreen with highly-scented flowers, is frequently found growing wild in our woodlands in different parts of the country. Not long ago when walking along the high road bordering a wood in Buckinghamshire, I saw a large number of small plants growing about the size of a lead pencil, and just a suitable size for grafting. When grafting is contemplated, the stocks should be potted up early in the autumn so as to become established. The grafted stocks should be placed in a close frame with an atmospheric temperature of 55° to 60°, airing the frame for an hour each morning, at the same time wiping the condensed moisture off the glass. In about ten days or a fortnight, the union of stock and graft will be sufficiently callused over to be removed from the frame. *W. H. Clarke, Aston Rowant, Oxon.*

The Week's Work.

PLANTS UNDER GLASS.

By J. G. WESTON, Gardener to H. J. KING, Esq.,
Eastwell Park, Kent.

The Palm-house.—Work in connection with the re-potting and top-dressing of Palms may soon be taken in hand. It is now fairly well known that most Palms will thrive and continue in a healthy state in much smaller pots or tubs than were at one time thought necessary. If Palms are healthy, and there is room in the pot or tub to apply plenty of water for the roots, there is no need to pot them into larger pots, always providing the plants, being gross feeders, are fed regularly with some good, artificial manure, and that the roots are never allowed to lack water. The above remarks apply principally to the stronger growing Palms as the *Kentias*, *Coryphas*, *Hyophorbe* (*Areca*), and *Phoenix*, most of which are much used for decorative purposes at the present time. Some of the more slender growing species like *Cocos Weddelliana*, and *Geonoma gracilis* require rather more careful treatment to keep them healthy. In the event of any of the latter being unhealthy and the soil sour, the roots should be washed out and re-potted in a pot of smaller size, being careful afterwards not to apply more water to the roots than is necessary, as they will be less active for a period. A lighter soil should be used for such Palms than is suitable for the stronger growing species. These latter succeed very well in loam with a little sand and soot added. When potting, ram the soil very firm, this being essential to keep them in small pots, otherwise they will soon lift themselves out of the pots. *Kentias* are probably the most useful of all Palms for decoration. *Cocos* and *Hyophorbes* (*Arecas*) are very graceful, but rather more tender; while for standing in draughty corridors, and putting up with general bad treatment, the hardier species of *Phoenix*, such as *P. tenuis* and *P. canariensis*, are useful for situations where better species would be sacrificed. Well-grown specimens of *Phoenix rupicola* and *P. Roebelinii* are very graceful for use upon tables, &c. Shading is a very important matter, and should be attended to early in the season, as dilatoriness in this matter may result in damage to valuable plants.

Bougardias.—These plants having been rested for a time in a cool house may now be cut back,

cleaned and placed in a moderately warm atmosphere. They will soon make plenty of young growths that may be used for cuttings. If preferred, the larger pieces of root may be taken off, cut up into small pieces, and placed in pans in the propagating frame. When they have commenced to grow, they may be potted up and grown on with the rest of the young stock, using a light, sandy soil with plenty of leaf-soil for the first potting, after which a rather stronger compost will be best.

FRUITS UNDER GLASS.

By ALEXANDER KIRK, Gardener to J. THOMPSON PATON, Esq.,
Norwood, Alloa, Clackmannanshire.

The vinery.—Muscat of Alexandria vines, which were started into growth last month, will now be swelling their buds, but their growth should not be hurried by excessive fire heat. The valves of the hot-water system should be turned on about 5 or 6 p.m., and be shut again about 8 a.m. in the morning, unless the weather is severe enough to necessitate a little artificial heat being applied during the daytime to maintain a temperature of from 55° to 60° Fahr. Maintain a humid atmosphere in the house by damping the borders and the paths twice daily, and if ventilation becomes necessary, through sun heat, close the house when the temperature has fallen to 80°. Do not allow excessive heat to radiate from the hot-water pipes at any time, for this is more harmful than allowing the temperature to drop a few degrees. Attend carefully to the watering of the borders, and use the tester to ascertain if they are dry, for the roots of Muscat vines will soon perish if the border is in the least degree overwatered. As soon as the buds burst into growth rub out all the weaker and leave only the strongest bud on each spur. In disbudbing young canes, leave only the strongest and best situated buds on each side of the canes. These will form the future fruit spurs, and should be 15 inches apart alternately on either side. Vines intended for planting in prepared borders in March should be kept in a dormant condition. Small, well-ripened plants of last year's growth in 7-inch pots are to be preferred to gross ones. Turf for dressing the borders may now be prepared. To every 3 tons of chopped turf we add 1 cwt. of coarse grade vine manure, one half-ton of lime rubbish, and a liberal supply of wood ashes. The whole is mixed thoroughly and wheeled on to the borders when convenient.

Vines which are passing out of flower will require to have the atmospheric temperature of the vinery lowered to 65° at night and 75° to 80° by day. Keep the atmosphere moist by damping the borders and paths once or twice daily. If the bunches show the slightest tendency to run out too long, reduce the moisture in the atmosphere and admit a little air by means of the top ventilators, meanwhile keeping a good heat in the water pipes. This treatment will have the effect of producing compact bunches, which are always desirable. Remove any bunches that will not be required, and tie up the shoulders of those that are to remain with a thin strip of matting. Thinning may now be proceeded with. Run a small strip of matting through the centre of the bunch; take the two ends of this in the left hand, and thus hold the bunch in position while it is being thinned. Begin at the point and thin upwards. Remove all stoneless berries and all that would grow inwards towards the bunch. Regulate the bunch by thinning out the berries, few or many, according to the variety. After the thinning has been done, test the inside border with the soil tester. Examine the sample of soil very carefully, and if it is dry apply a good watering with tepid water. Guard particularly against over or under-watering at all times.

Vines in pots.—If the early supply of Grapes is produced by pot vines growing in pits, the atmospheric heat should be a few degrees higher than that recommended for the vinery. Let all water afforded these be applied to the roots in a tepid condition. Manure water may be applied once a week. Ventilate the pits with great care; damp the paths twice daily. The vine shoots should be pinched at two leaves beyond the bunch, and the sub-laterals at one leaf; afterwards rub out all growth. Remove any bunches that will not be required, and tie up the shoots neatly to the stakes.

Forced Strawberries.—Plants that are now coming into flower must be allowed a temperature of 60° at night and 70° to 75° during the daytime. During fine weather they should receive a little ventilation daily, but cold draughts must be avoided. Pollinate the flowers at mid-day with the camel-hair brush, and keep the atmosphere of the house, in which they are growing, dry. Give abundance of tepid warm water at their roots and a little manure water twice weekly. As soon as the fruits are set remove the pots to a shelf near to the glass. Thin out the weaker fruits, leaving eight or 10 Strawberries on each plant. Support the bunches of fruits with forked twigs, or better still with wire stakes that can be obtained from the sundriesman. Grow the plants in a moist atmosphere, but guard against excessive moisture, otherwise mildew will put in an appearance. The variety *Royal Sovereign* is especially subject to this disease. As soon as the berries commence to colour discontinue the manure water, and keep the atmosphere drier and warmer to promote a fine flavour in the fruits. A successful batch of plants should be brought into heat every fortnight; a vinery about to be started with a temperature of 45° to 60° Fahr. will suit them, but they must not be hurried into growth. *Vicomtesse Héricart de Thury* is a suitable variety for early culture in pots.

THE KITCHEN GARDEN.

By WILLIAM HONNESS, Gardener to C. COMBE, Esq.,
Cobham Park, Surrey.

Winter Onions.—As soon as the ground is in good condition for being worked, let the winter or August-sown Onions be planted out. A good dressing of dung and soot should previously have been applied to the soil. Before lifting the young plants from the seed-bed, the soil of the bed should be loosened with a fork, care being taken not to keep the plants out of the ground longer than is absolutely necessary. The plants should be put in at distances of 6 inches apart, in rows drawn at 1 foot from each other.

Garlic and Shallots.—Plant out the former at a depth of about 2 inches, but on heavy soils Shallots should be planted in shallow drills, drawn at 12 inches apart, allowing a space of 6 inches between each bulb.

Celeriac.—Seeds of *Celeriac* should now be sown in a box, which should be placed in an atmospheric temperature of 55° Fahr. Cultivate the young plants when they have appeared above the surface as strongly as possible without "coddling." Transplant them as soon as they are large enough, and gradually harden them off as growth and the season advance. If a cold frame can be spared for them at about the third week in March, finer plants will then be available in April, when it is time to finally shift them into the open.

Celery.—Where Celery is required early in the season, a small sowing should now be made, and the young plants will require similar treatment to that recommended for *Celeriac*.

Brussels Sprouts being generally in great demand and one of the principal winter-vegetable crops, should be grown in at least two batches, the first sowing to be made at the present time in light soil in a cold frame, or in a box, which should be placed in a cold greenhouse. This structure will afford sufficient protection, and induce hardness, which must be the first consideration where vegetables are sown and cultivated in their early stages under artificial treatment.

Rhubarb.—If fresh plantations or beds are found to be necessary, a division of any old stools to hand should now be made, reducing them to single crowns, or if it is intended to give any of the more modern varieties a trial, these should be purchased immediately and planted 4 feet apart in rows, allowing a similar distance between the rows. Established beds that are to supply the season's demand for the kitchen or for the making of wine or jam, should now receive a dressing of dung, which should be well dug in, finally covering all the crowns with long litter as a protection, which will assist in obtaining an early supply of Rhubarb from the open garden.

Broad Beans.—Make a further sowing of these as soon as the ground is in a proper condition for the work, selecting Long Pod and Green Windsor varieties.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir Trevor Lawrence, Bart., Burford, Surrey.

Aërides and Saccolabiums.—These beautiful Orchids are undeservedly neglected by most Orchid cultivators, but when well grown they are capable of producing very fine racemes of fragrant flowers. In collections which possess any of the following varieties—*Aërides Lobbii*, *A. Fieldingii*, *A. Houlletianum*, *A. odoratum*, *A. suavissimum*, *A. virens*, *A. Larpentæ*, *A. quinquevulnerum*, *A. Lawrenceæ*, and its yellow-tinted variety, *Sanderianum*, &c., also such *Saccolabiums* as *S. guttatum*, *S. giganteum*, *S. præmorsum*, *S. retusum*, *S. violaceum*, &c., it may be noticed that the points of the old roots, which have been closed during their period of rest, are now turning green; therefore, the present is a suitable time to thoroughly overhaul the plants. Each one should be well cleared of scale insects, which are generally found on the stem and low down in the axils of the leaves. Any plants needing more rooting space should be re-potted. Pots are the best receptacles for *Aërides*, but for *Saccolabiums* teak baskets that may be suspended from the roof are preferable. Rough, unchopped, but clean-picked sphagnum-moss is the best material for them to root into, inserting among the moss moderate-sized pieces of crocks to ensure porosity, and covering the surface with a conical mound of freshly-gathered sphagnum-moss. Plants that do not need re-potting should have the exhausted material carefully picked out from the roots, and fresh sphagnum-moss substituted. Following this treatment the plants should be placed in the warmest house, and be protected from all strong sunshine. One thorough watering will be sufficient to last for several weeks to come, but their immediate surroundings should be kept fairly moist by damping the stage between the pots two or three times each day. After such a period the surface moss will have become dry, and may then be occasionally sprinkled or sprayed over with tepid rain water. Any of the plants that have had their roots disturbed by re-potting, and which may in a short time produce flower-spikes, should have such spikes pinched out, which will assist the plant to make a fresh start. The cooler-growing *Aërides*, which comprise such varieties as *A. crispum*, *A. crassifolium*, *A. Lindleyanum*, and *A. Warnerii* thrive best in the *Cattleya* or intermediate house, where they require a well-ventilated position.

Cattleyas.—*C. Trianae* and *C. Percivalliana* should, as they pass out of flower, be kept rather drier at the root until growth recommences. *C. gigas* and *C. Warnerii* are now starting into growth, and will need to be watered. Both species should be placed well up to the roof of the *Cattleya* or Mexican house, and the more light they can get without strong, direct sunshine the more likely are they to bloom satisfactorily. These two species should not be disturbed until they have completed their growth, for they will then produce many new roots.

In the *Mexican house*, *Odontoglossum citrosimum* is commencing to grow, but the plants need no water until the growths are well advanced, or when the flower-spikes are seen pushing up through the centre; then the compost should be thoroughly watered, and the plants subjected to a moister atmosphere. When the spikes appear, wrap a piece of wadding around the growths to protect them from such insect pests as cockroaches, beetles, or woodlice; if these abound, spread some "Beetle-cute" around their haunts, and they will quickly disappear.

THE FLOWER GARDEN.

By A. C. BARTLETT, Gardener to Mrs. Ford, Pencarrow, Cornwall.

The shrubbery.—All planting should be finished during this month, so as to allow time for the plants to form new roots before the drying winds set in. In all cases where it is necessary, afford a stake to the newly-planted shrub, in order to make it secure against wind, and affix an indelible label to new or rare varieties. At this season a mulching is even more essential than in the autumn. Examine the ties upon recently-planted shrubs to see that they are not likely to chafe the branches. Any needful pruning of those deciduous shrubs which flower on the current year's growth must be completed as

soon as possible. Those which flower on the previous season's wood must be pruned when they pass out of flower. The flowers of the invaluable *Winter Sweet* (*Chimonanthus fragrans*) will soon be past, but the less pruning this shrub receives the better it will flower. When growing against a wall I have found it best to cut away whole branches, as they become crowded, rather than to spur back the shoots. Persistently cut out all green shoots that appear in white and golden-variegated shrubs, or these reversions will grow strongly at the expense of the more decorative parts. Established shrubberies will require some soil-enrichment, and where it is possible, this should be lightly forked into the soil, as in doing this the soil becomes aerated, provides a better surface for the necessary hoeing later on, has a more cleanly appearance, and renders the manure more readily available to the roots. But when treating surface-rooting plants—more particularly *Rhododendrons* and *Ghent Azaleas*—this would lead to the destruction of many roots, and the manure must, therefore, be applied as a top-dressing.

Herbaceous borders.—As weather and opportunities permit, any necessary alterations or arrangements should be carried out. Many of the stronger-growing plants are probably occupying too much room and must be restricted. This is best done by taking up the whole clump and removing sufficient from the outside of the clump to replant. If they are to go back to the old position, the soil should be well broken up, and a suitable dressing incorporated with it. The spaces soon to be planted with *Pentstemons*, *Gaillardias*, summer-flowering *Chrysanthemums*, &c., should be well dug and heavily manured.

Lawns.—Continue to frequently sweep and lightly roll the grass. A light top-dressing of fine soil and wood ashes will quickly improve a poor sward, but it is necessary to exercise caution as to the source from which it is obtained, or a crop of weeds will take the place of the finer grasses. Turf-laying should only be proceeded with during fine weather; it is impossible to do the work properly between showers. Moss may be removed by scouring it with an iron rake. Where the rainfall is heavy, moss puts in an appearance towards the end of the autumn and dies away in the spring when drier conditions prevail. The periodical sweepings and rollings usually serve to keep the moss from becoming too much in evidence.

THE HARDY FRUIT GARDEN.

By J. MAYNE, Gardener to the Hon. MARK ROLLE, Bicton, East Devon.

New Strawberry-beds.—Where spring planting is contemplated, the preparation of the ground should be undertaken as soon as it is in a fit state to be worked. Trench the soil 2 feet deep or double-dig it, the latter term merely meaning the turning upside down of the second spit of soil. Place a layer of manure at the bottom of the second spit as well as between that spit and the top spit. Allow the ground to settle until the end of the present month, or early in March, when planting may be done. The distance to be allowed from plant to plant must depend upon the variety, but 2 feet asunder is a pretty general rule, although many set out the plants at 1 foot apart in the row, chopping out every alternate one at the end of the fruiting season 16 months hence.

American blight.—All cultivators of fruit are acquainted with this pest that attacks Apple trees more or less throughout the country, and this, the dormant season, affords an opportunity of battling with the enemy. Paraffin emulsion, spirits of turpentine, or methylated spirits applied with a fairly stiff brush, and thoroughly worked into every crevice of the bark, proves the most effective remedy. The soil or turf should be pulled aside, and the roots near the base of the trunk should be treated in like manner, as this proves a rare hiding place for the depredators. This practice should be persevered with throughout the summer, by the end of which few, if any, of the insects ought to be found. Do not touch the foliage with either of these spirits, or much injury may be done.

Grass orchards.—In the western counties it is general to stock these with sheep or pigs, but recently-planted trees must be well protected with wire netting, or the sheep will nibble the bark to such an extent that growth will become stunted; canker will set in, and eventu-

ally many a tree will have to be destroyed as worthless. Where this, or other effective protection is afforded, there is no better way of manuring the land, as grazing can continue right up to the time the fruit begins to fall, and where nettles abound pigs will unearth every root, and quickly rid the ground of this undesirable weed. In our case there is no stock to turn in, so we apply an annual top-dressing of waste soil, decayed leaves, grass, &c., and every few years a good percentage of fresh, slaked lime is added to the above compost, mixed together twice, and then distributed over the turf. We mow the grass twice in the summer, and the grass is used for mulching fruit-tree borders, especially those of the Apricot and Peach. Where drainings from the farmyard are plentiful, the liquid may well be utilised on orchard land at this time of year.

General remarks.—The thoughtful fruit-grower will have taken advantage of the firm state of the ground recently to get the necessary manure wheeled or carted on to the borders. Up to the time of writing, the small, mischievous birds that often cause injury to the fruit buds, have not commenced operations, but a keen look-out must be kept, especially during hard frost, which prevents their getting any food from the ground. During inclement weather examine netting of all kinds, any netting used for the protection of ripe fruit having got broken during the past year, and worth repair, should be put in order. One pound of small twine will go a long way in pulling rents together, and where hexagon netting is used as roller blinds in protecting wall fruit trees in spring, a small patch here and there of the same material will often make them serviceable for another season or two. Obtain the required supply of new netting, so that it will be available when needed for use.

PUBLIC PARKS AND GARDENS.

By W. W. PETTIGREW, Superintendent of the Parks and Open Spaces in the City of Cardiff.

Seats (continued).—There are many different kinds of garden seats, ranging from the ordinary cheap rustic seat to the large expensive kind with ornate cast-iron ends and supports. It must be admitted that for all practical purposes the less complicated a garden seat is, the better, and one having the seating and back made up of only six good-sized battens, is preferable to one consisting of 13 or 14 strips of wood—a very common type. It is also much better for the ends of seat battens to be free instead of being bolted in the grooves of cast-iron frame work. Seats of this latter pattern are constantly requiring repairs on account of the wood rotting in the grooves, and their upkeep is in consequence somewhat expensive. Seat battens are commonly made from pitch pine, although it is by no means the most suitable timber for withstanding the effects of our changeable climate. Teak and English Oak are the best for this purpose, and last very much longer than most other woods, but on account of their higher price are not generally used. Until recently, the iron work employed in the construction of seats was invariably cast, but in the better class of seats now coming into vogue, simple but strong wrought iron frames are used instead. Cast iron being so easily broken is not a suitable material for the framework of seats that have to be moved about from time to time, for if once damaged, it can hardly be repaired again. Wrought iron, on the contrary, can easily be welded together if by chance it gets broken.

Housing and painting of seats in winter.—It is convenient to have a large barn or shed, in which garden seats may be stored and painted during the winter months. When possible, seats should be stored several weeks prior to being painted, so as to ensure the woodwork becoming thoroughly dry before a brush is put upon it, and they should remain under cover for as long a period as possible after they have been painted, in order to allow the paint to get perfectly hard before being exposed to the weather. Many people like their garden seats oak-grained and varnished, but, for standing wear and tear, a couple of good coats of dark green paint, with a final coat of hard outside oak-varnish is hard to beat. Teak-wood, I understand, simply requires a dressing of linseed oil, with a coat of varnish to keep it in good condition.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

Illustrations.—The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY, FEBRUARY 10—

German Gard. Soc. meet.

THURSDAY, FEBRUARY 21—

Linnean Soc. meet.

Manchester & North of England Orchid Soc. meet.

FRIDAY, FEBRUARY 22—Roy. Bot. Soc. meet.

British Gard. Assoc. meet at Kingston.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—39° 6'.

ACTUAL TEMPERATURES:—

LONDON.—Wednesday, February 13 (6 P.M.): Max. 42°; Min. 37°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, February 14 (10 A.M.): Bar., 29° 8'; Temp., 41°; Weather—Bright.

PROVINCES.—Wednesday, February 13 (6 P.M.): Max. 48° Ireland S.W.; Min. 37° Scotland N.E.

SALES FOR THE ENSUING WEEK.

MONDAY—

Roses, Azaleas, Perennials, Lilies, and other Hardy Bulbs, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.

TUESDAY—

Clearance sale of Nursery Stock at Grove Park Nursery, Chiswick, by order of Mr. J. Smith, by Protheroe & Morris, at 12.

WEDNESDAY—

Hardy Bulbs and Plants, Azaleas, Palms, and Plants, at 12; Roses, Fruit Trees, &c., at 1, 80 and 4, at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

Plants, Roses and Lilies, at Stevens' Rooms, King Street, Covent Garden, W.C.

FRIDAY—

Azaleas, Roses, Border Plants and Bulbs, at 12.

Imported and Established Orchids in variety, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

Having so recently commented on the report of the Royal Horticultural Society for the past year, there is little left for us to say regarding the annual meeting. Sir Trevor Lawrence, in moving the adoption of the report, passed in review its principal features, and congratulated the Fellows, as well he might, on the flourishing condition in which it now is. Sir Trevor has indeed earned the congratulations of the Fellows, and must feel justifiable pride on seeing the old society not only rescued from its at one time desperate position, but now raised to a state of prosperity beyond what it has ever previously attained. With what different feelings must the President now address the Fellows to those he must have experienced in the bad old days. Sir Trevor was careful to assign credit where it was due, but the Fellows have shown that they are not unmindful of the services rendered by the President himself.

In the course of his remarks, Sir Trevor took occasion to comment on the great loss sustained by horticulture in general by the death of the learned and genial Comte de

Kerchove de Denterghem, whose incessant labours in the cause can in some degree be appreciated by those who have taken part in the Ghent Quinquennials. The death of Sir Michael Foster, who was a staunch friend to the society, was probably not mentioned from the fact that the President was alluding solely to the events of the year 1906.

The hall, which gave rise to dismal forebodings, has proved so attractive that the receipts obtained from letting it for various purposes when it is not required for the society's own use have sufficed to defray all, or nearly all, the very heavy outgoings for rates and taxes, and for ground rent. The Summer Show is, generally speaking, not a financial success, but last year at Holland House a small profit was made, and it is to be hoped that this year the balance may be equally favourable. This year, it may be added, occurs the tercentenary of Holland House. Amid the vast changes going on around us in London and elsewhere, this fact comes as a reminder that there is, nevertheless, a marked stability in British institutions.

When it came to the turn of Mr. Gurney Fowler to explain the items on the balance-sheet, we had one of those straightforward, lucid statements that he has taught us to expect from the treasurer. Not only is the society flourishing, but, like a prudent financier that he is, the treasurer is looking ahead, writing off certain sums for certain depreciations of buildings and appliances, including the glass roof of the hall, which it is supposed may require substantial repair within 40 years. As this will be an expensive business a sum of £120 a year is set apart to form a fund for the renewal of the roof when needed.

Nothing was said about the Lindley Library, but we trust that that may now be dealt with in a manner commensurate with its value and importance.

The usual well-earned compliments and thanks were accorded to the committees and the members of the staff, and as no one had any question to ask or criticism to offer, the meeting was brought to a highly satisfactory termination.

OUR SUPPLEMENTARY ILLUSTRATION shows the beautiful Water Lily that was exhibited by Lord HILLINGDON, under the name of *N. atropurpurea*, at the meeting of the Royal Horticultural Society, on July 31 last, when it received an Award of Merit from the Floral Committee. It belongs to the section of hybrids raised by M. Marliac. It is quite the deepest coloured, perfectly hardy Water Lily, and it has curled anthers, the orange-yellow colour of which is very effective. It is a flower of large size, being something like 9 inches in diameter, and the blooms are produced with the greatest freedom. Mr. A. R. ALLAN, the Gardener at Hillingdon Court, writes: "Nymphæa atropurpurea is a particularly showy variety, with large flowers, from 6 to 9 inches in diameter, and having yellow anthers. The petals are incurved, and of a very deep shade. It attracts much attention when planted between other paler varieties, as is done in these gardens. To my mind this is the most pleasing of all the Nymphæas, being a good grower, and without excessive foliage. It is planted about 18 inches below the surface of our Lily pond, fully exposed all day to the sun. At the time the flower, from which the illustration was prepared, was cut, there were 30 fully expanded blossoms, and as many more buds ready to burst."

ROYAL METEOROLOGICAL SOCIETY.—AN ordinary meeting will be held at the Institution of Civil Engineers, Great George Street, Westminster, S.W., on Wednesday, February 20, at 7.30 p.m. The papers to be read will include:—1, "Report on the Phenological Observations for 1906," by EDWARD MAWLEY, F.R.Met.Soc. V.M.H.; 2, "The Metric System in Meteorology," by RICHARD INWARDS, F.R.A.S.

THE FUTURE OF GARDENERS.—We would call the attention of our readers to the excellent remarks of the president of the Scottish Horticultural Association on the progress of gardening and the means of promoting it. We are on this occasion only able to publish a portion of the address, but in our next issue we hope to be able to give the remainder. His account of the botany system, we believe, is not by any means universally applicable nowadays, but there can be no doubt that whilst in some establishments means are taken to secure the reasonable comfort and welfare of the young gardeners, in others the disgraceful state of things portrayed by Mr. THOMSON still exists. One object of the British Gardeners' Association is to endeavour to remedy these defects. The president is a warm advocate of the necessity for suitable education. Concurrently with this improved education, general and technical, must come an augmented remuneration and an improved social position. True, very much depends upon the man himself. No association can make "character," but it can mould it and afford the opportunity for its development and ensure that "conduct" shall reap its appropriate reward. The president says the association has begun at the wrong end. It may be so, but for our part we do not think it will make much material difference at which end a beginning is made, so long as a fair start is accomplished. The first thing to be done is to secure unity of purpose and co-operation. That done, circumstances will soon show which is the best course to pursue in fulfilment of the aims.

NATIONAL POTATO SOCIETY.—The secretary informs us that the society's show this year has now been fixed to take place at the South Eastern Agricultural College, at Wye, in Kent, on Wednesday, October 2. Arrangements are being made for holding a series of Potato trials at the College gardens, under the direction of Mr. W. P. WRIGHT, the horticultural superintendent, in addition to the trials which will be continued at the Cambridge University Farm at Impington, Cambs., and elsewhere.

THE VEITCH MEMORIAL TRUST.—At a recent meeting of the Trustees a gold medal was unanimously awarded to Mr. WORTHINGTON G. SMITH in recognition of his invaluable services to horticulture as a botanical draughtsman. Mr. SMITH has been so long associated with this journal, both as a botanical artist and a student of fungi, that we feel no little gratification at this recognition of our friend's prolonged services. A similar medal was bestowed on Mr. J. G. BAKER, whose garden monographs are so highly valued. At the same meeting a most welcome addition to the funds of the Lindley Library Trustees, in the shape of a donation of £25, was made, and arrangements were made for the presentation of prizes at the special meeting of the York Gala to be held next year (1906).

SIR MICHAEL FOSTER.—The current number of *Garden Life* contains two portraits of the deceased physiologist, together with views of his garden and an interesting account of a chat with its owner about Irises. Speaking of the length of time required by the seeds of some Irises to germinate, Sir MICHAEL is reported to have said that he had repeatedly raised seedlings from seeds which had been lying in one pot for periods varying from five to ten years, in two instances for 13 and 15 years respectively, and in one case for 18 years. "There are still a dozen or more of

NYMPHAEA "ATRO-PURPUREA," A RICH PURPLE-COLOURED FLOWER, HAVING CURLED, ORANGE-COLOURED ANTHERS,
FROM THE GARDEN OF LORD HILLINGDON.

Temple Press Ltd., Printers, 7-15, Rosebery Avenue, London, E.C.

that 18-year-old seed sound and hard, and, I believe, still germinable. I am wondering whether it or I will come to an end first." Unfortunately there is no longer cause for speculation on this point.

BRITISH GARDENERS' ASSOCIATION RICHMOND (SURREY) BRANCH.—A public meeting of the Richmond and District Branch will be held in the Fife Hall, Kingston-on-Thames (close to Kingston Railway Station), on Friday, February 22, 1907, at 8 p.m. Chairman, Mr. ALEXANDER DEAN. An address will be given by Mr. R. HOOPER PEARSON.

LINNEAN SOCIETY.—There will be a meeting on Thursday, February 21, at 8 p.m., when the following papers will be read:—1, "The Percy Sladen Trust Expedition to the Indian Ocean," Mr. J. STANLEY GARDINER, M.A., F.L.S., &c.; Introduction—Part I. Ceylon to Mauritius; 2, Mr. R. C. PUNNETT, M.A., "Land Nemertean; with a Note on the Distribution of the Group"; 3, Mr. L. A. BORRADAILE, M.A., "Land Crustaceans"; 4, Mr. P. CAMERON, "Hymenoptera"; 5, Mr. F. F. LAIDLAW, M.A., "Dragon Flies"; 6, Prof. A. FOREL, "Fourmis des Seychelles, Admirantes, Farquhar et Chagos"; 7, Prof. G. H. CARPENTER, B.Sc., "Pycnogonida."

FLOWERS IN SEASON.—Mr. J. SMITH, V.M.H., of the Daisy Hill Nurseries, Newry, sends us male catkins and shoots of a variety of Alder, *Alnus incana aurea*, the bark of which is of a deep shining red, like that of some species of *Cornus*. The tree must be very effective in the winter season.

THE PREVENTION OF CORRUPTION ACT.—A correspondent writes to suggest that nurserymen and seedsmen, instead of reducing the price of seeds and plants to their customers, should give the amount they would have given to the gardener to the gardening charities, such as the Gardeners' Orphan Fund and the Gardeners' Benevolent. This suggestion would have to be carried out with the full knowledge and approval of the purchaser, else it would be open to most of the objections and penalties pertaining to the discount system.

NATIONAL FEDERATION OF FRUIT AND POTATO TRADERS' ASSOCIATIONS.—The annual dinner of the National Federation of Fruit and Potato Traders' Associations will take place at the Trocadero, on Tuesday, March 19 next, when Sir ALBERT K. ROLLIT, Kt., will preside.

THE SEEDLESS APPLE.—From Mr. NANSCAWEN we have received specimens of an Apple perfect except as to the seeds which are abortive. The ovules are formed, but they do not ripen into perfect seeds, and no embryo is formed in them. This points to the circumstance that the pollen is either not properly pollinated or that the pollen is not in good condition. Mr. NANSCAWEN tells us the tree has been on the estate longer than anyone can remember. Unisexual flowers are not at all uncommon in the Rosaceæ. Perhaps if the pollen of some other Apple were dusted on to the stigmas the seeds would be perfected.

ECONOMIC BOTANY.—The Council of the University of Manchester proposes to establish a lectureship on this subject. "The lecturer," says the *Lancet*, "will give instruction to special classes, and will assist in arranging the collections of plants and plant-products possessed by the University, examine and report on plant-diseases, timbers, and other vegetable products, and conduct special researches in economic botany."

THE UNIVERSITY OF CHICAGO.—Mr. J. D. ROCKEFELLER has endowed the University with the sum of £540,000, besides £43,000 for current expenses. On the whole, Mr. ROCKEFELLER has contributed more than £4,000,000 to this University.

PROFESSOR DR. KLESS, until now resident at Halle on the Saal, has been appointed to succeed the late PROFESSOR DR. PFITZER, as director of the Botanical Institute and Garden of the Heidelberg University.

DR. OTTO KUNTZE died suddenly, on January 28, at San Remo, where he had been residing for several years. To many of the readers of the *Gardeners' Chronicle* the deceased will be known by his controversy with the botanical world as regards nomenclature. Dr. KUNTZE was a self-made man. He began life as an office clerk; when he wrote his first botanical book, a *Flora of Leipzig and surroundings*. Having at the age of 27 years made his fortune, he decided to take his degree. He subsequently travelled in South Africa, South America, &c., and collected an enormous number of plants. These he described in his *Revisio Generum Plantarum*. With this publication his controversy began, which he continued until a few days before his death, when he sent out a protest against the last botanical congress at Vienna. [One of, if not the very last of, his letters appeared in our last issue.] However aggressive he was in his publications as regards nomenclature, he was a pleasant, kind-hearted friend to many, and ever ready to help and to allow the use of his rich library and herbarium. *Alwin Berger, La Mortola*.

MUSA BASJOO.—The *Revue Horticole* announces the flowering of this species (also known as *M. japonica*) in the open air in M. DE VILMORIN's garden at Verrières, near Paris. The plant is growing in a sheltered but sunny position, and is protected during the winter by a thick layer of dead leaves, whilst the stem, or what answers to the stem, is protected by straw and a hood of the same material of such a shape as to throw off the water if placed over the whole.

FLORA OF NEW SOUTH WALES.—"Botanists have long acknowledged that the vegetation of New South Wales is remarkable for its immense variety, and the dissimilarity of a large number of species from those of other countries. There are 3,374 species and 549 varieties (i.e., 3,923 named forms) of plants, including phanerogams (flowering plants) and vascular cryptogams (Ferns, 122 species and 7 varieties), described and recorded as having been found in New South Wales. The number slowly increases every year. Moreover, this enumeration takes no cognisance of the very large number of mosses, lichens, sea-weeds, and fungi also occurring in the State. The first three groups are little utilised, but the fungi are of enormous practical importance, less, perhaps, because of their direct utilisation (and even that in the case of a few edible species, e.g., the Mushrooms and the Jew's ear fungus, is considerable), but because of the power of the minute species, e.g., moulds and rusts, to injure and even destroy crops and other cultivated plants. An adequate account of these four classes of plants can only be given by specialists. The genus *Eucalyptus* comprises the principal forest vegetation of the State. It includes 89 species and 25 varieties, and some are added every year. Those which have smooth trunks are known as gums, and this term is qualified by adjectives such as white, blue, and red. Others have rough bark, and are known as ironbark and stringybark. The Wattles (*Acacias*) are worthy of more extended notice than can here be afforded them. Some are only 3 or 4 inches high, while others are over 100 feet, but the majority are shrubs or small trees. There are 122 species and 26 varieties of them, and they are found all over the State. They are a delight to the horticulturists, and they are highly prized by the tanner, the timber merchant, and the grazier." *The Year Book of New South Wales*, p. 115.

DEATH OF THE SULTAN'S GARDENER.—ADAM SCHLERFF, garden-director to the SULTAN at Constantinople, died on January 12. The deceased was born at Frankfurt on the Main in 1834, and entered the SULTAN's service as foreman in 1857. He had the superintendence of sixteen of the Imperial gardens.

LORD HOWE'S ISLAND.—"The flora of the island is in great variety, forming in all directions; the most picturesque of shady forests; the prevalence, however, of Palms (of the genus *Kentia* of Blume) and of Banyans (*Ficus columnaris* of Moore) form perhaps its most remarkable feature. Single trees of the latter in many instances cover acres of ground, while the Palms, countless in number, run up to 50, 60, and 70 feet in height, all of which, added to the colour of the water and the mountain, islet, and cliff scenery, give to the little isolated spot an unmistakable charm. The climate is peculiarly equable: Frosts are unknown, while in summer the thermometer seldom rises above 80°. Rain is abundant and frequent." *The Year Book of New South Wales*, p. 57.

A BIG HAUL OF QUEEN WASPS.—Whilst engaged in removing the lath blinds for painting from several of the glasshouses at Wargrave Manor, a colony of queen wasps was discovered. They were collected in a glass jam bottle and found to number 265. Mr. D. TURNER, the gardener, exhibited them alive at the meeting of the Wargrave Gardeners' Association held on February 6, and received the thanks of his fellow-gardeners for his services in ridding the district of so many of these objectionable pests.

THE RAINFALL during the past month in *Leonardlee Gardens*, Sussex, amounted to 1.89 inches. Rain was recorded on eight days only. This is in strong contrast, writes Mr. W. A. COOK, to January, 1906, when rain fell in these gardens on 20 days to the amount of 5.61 inches.

SILVER MEDALS FOR COTTAGE GARDENERS.—The Royal Horticultural Society, in granting to the Surrey Education Committee annually two silver Knightian medals, to be given each year to the worker of the best cottage garden and best allotment in the county, does so because the Society, being now a considerable landowner in Surrey, it realises that it has duties as well as rights. The past year was the fourth in which these medals have been awarded, and so keen is the desire to secure one that great efforts are made from year to year by workers to bring their gardens up to a high condition of cultivation. No competitor can take a medal twice in less than six years. As a rule, the presentations are made subjects of great local interest, some influential person being invited to give the medals. All those whose gardens are judged by the county horticultural instructor on a numerical basis are eligible. Last year's medal for a cottage garden was recently presented to Mr. A. DENNIS, a platelayer, for a capital, steep, sloping garden at Shenley; and the one for allotment to Mr. W. THOMPSON, of New Malden. In each class there were several close competitors.

Publications Received.—*Jamaica Bulletin of Miscellaneous Information*. January. Contents: Three Trinidad Orchids, Waste Organic Substances as Manures, Bamboo Notes, &c.—From the United States Department of Agriculture. Bureau of Entomology, Bulletin No. 61. *Laws in Force Against Injurious Insects and Foul Brood in the United States*. Compiled by L. O. Howard and A. F. Burgess.—Technical Series No. 14. *The Bacteria of the Apiary*; with Special Reference to Bee Diseases. By G. F. White.—Bureau of Plant Industry. Bulletin No. 102, Part I. *Summary of Recent Investigations of the Value of Cacti as Stock Food*, by David Griffiths and R. F. Hare.—Bureau of Entomology. Circulars: No. 77, *Harvest Mites or "Chiggers"*, by F. H. Chittenden; No. 78, *The Slender Seed-Corn Ground Beetle*, by

F. M. Webster; No. 79, *The Brood Diseases of Bees*, by F. F. Phillips; No. 80, *Melon Aphid*, by F. H. Chittenden; No. 82, *Pinhole Injury to Girdled Cypress in the South Atlantic and Gulf States*, by A. D. Hopkins.—*Bulletin of Miscellaneous Information, Kew*. Appendix V. 1906. This is the Index to Kew Bulletin, 1887—1906. We note with satisfaction the publication of this brought up to date.—*The Garden City* reminds us that this year the eighth annual meeting of the Association will be held.—*The Museum Gazette and Journal of Field Study*. January. Conducted by Dr. Jonathan Hutchinson, E. W. Swanton, and many others. Full of interesting notes and brisk useful articles.—Ontario Department of Agriculture. Macdonald Institute, Ontario Agricultural College. Bulletin No. 152.—*Gardening for Schools*, by S. B. McCready. North Dakota Agricultural College. Government Agricultural Experiment Station for North Dakota. Bulletin No. 71.—*Flax Culture*, by H. L. Bolley.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

BLUE HYDRANGEAS.—I should be inclined to answer Mr. James Brown's query, p. 68, as to whether "the real cause of some Hydrangeas producing blue flowers has ever been satisfactorily cleared up" in the negative, and I venture to assume that, beyond its being due to what has been vaguely described as "something in the soil," the predisposing cause has never yet been ascertained. Many theories have been advanced to account for this change of colour, but every one of these is capable of disproof. Mr. Mayne and Mr. Bear, p. 93, attribute this blue colouring in the flowers to the presence of iron in the soil and to shade respectively; other writers attribute it to the influence of a peaty soil, but many instances may be cited where neither of these conditions are responsible for the blue colouring. Some years ago I was in Abbotsbury Castle gardens at a time when the Hydrangeas were in flower. As mentioned by Canon Ellacombe in his paper on "The great drought of 1896," these gardens are heavily impregnated with iron, yet, in spite of this, all of the numerous Hydrangea plants except two bore pink flowers. These two plants were growing in shade, and Mr. J. Benbow, the gardener, considered, as does Mr. Mayne, that the colouring was due to their being shaded. Against this factor, however, I may mention that the bluest Hydrangeas that I have ever seen were growing at the edge of a steep cliff overhanging the sea, in South Devon, where they never experience a moment's shade from dawn till sunset. A difference of a few feet will often bring about a change of colour. Of this two instances are known to me. In the one case Hydrangeas are growing on either side of a little streamlet, which runs about 8 feet below the level of the ground, and the plants on one side bear pink flowers, those on the other side, blue. In the other case enormous bushes line both sides of a carriage-drive, those on the right hand producing pink blossoms, those on the left hand, blue. In both cases it would be imagined that the soil on either side of the streamlet and drive would be similar, but there is evidently some constituent present on the one side which is lacking on the other. It is sometimes stated that by watering these plants with a liquid heavily impregnated with iron or alum, or by burying iron filings in the ground, blue flowers may be secured, but though a certain change of colour may be effected, the clear blue of naturally grown plants is absent. Even where soil is obtained from ground producing blue Hydrangeas the result is not necessarily satisfactory, for a plant grown by a friend in earth, taken from among the exceptionally blue-flowered plants already mentioned, bore pink and not blue blossoms. My experience is that blue Hydrangeas are to be found in all manner of soils, whether gravelly, peaty, loamy, slaty, or iron impregnated, and in sunny as well as in shady spots. It is said that near Angers, in France, a soil is found, rich in silica, organic matter and humus, that invariably turns Hydrangea flowers blue. S. W. Fitzherbert.

—These gardens contain some hundreds of Hydrangeas: indeed one might almost say that Heligan is a garden of Hydrangeas, and in November last they were a glorious sight.

Many are growing under the shade of large trees, others in the open, and the majority of their flowers are of a lovely shade of light blue. I believe that shade and a certain quality in the soil are necessary to produce this beautiful blue in the flowers. These gardens are situated quite close to the sea, and this may also have something to do with the colouring. I have seen blue flowers in Hydrangeas at Penrhyn Castle, North Wales, the seat of Lord Penrhyn, which is also close to the sea, and I noticed many of the plants were growing in the shade. G. S. Jordan, *Heligan Gardens, Cornwall*.

I have been much interested in the correspondence on this subject. We have some old plants which produce flowers as blue as one could wish, but if cuttings are rooted from these and grown to flower on a single stem with large inflorescences, every one of these young plants will produce pink flowers. After flowering I cut the old inflorescence off, and when they flower again the following year all the flowers are blue and remain so afterwards. Whether I repot the plants or not it does not affect the colour. No special mineral or chemical is used in any way, and the plants are all fed and treated alike. We only shade while the plants are in flower. We do not grow Hydrangeas permanently out-of-doors, as they will not stand the winter here. T. B. Archer, *The Hazels Gardens, Prescott, Lancs.*

SOWING SMALL SEEDS.—The patience of a young gardener is often tried when he has to transplant seedlings of such plants as Lobelias, Begonias (tuberous and fibrous), Gloxinias, Streptocarpus, Nicotiana, etc., which have been sown in pans or boxes as thickly as hairs on a cat's back. All small seeds should be sown evenly and thinly, the result being strong healthy seedlings, which, after being pricked out, soon make good, strong plants. The same thing applies to the sowing of many sorts of vegetables, whether sown early in boxes and frames, or in the open ground. Much seed is wasted yearly through being sown too thickly. W. H. Collett, *Huntsham Court Gardens, Bampton, N. Devon*.

GAS TAR AS AN INSECTICIDE.—The vines in four vineries of which I had the care five years ago were covered with mealy bug. After pruning and removing the loose bark they were thoroughly washed twice with Gishurst compound, and afterwards painted with a mixture of nine parts clay, one of gas tar, one of soft soap, and half of sulphur. These ingredients were stirred in boiling water, and when the liquid was cold the rods were painted with it, but not the young wood and buds. I use this preparation each year, and have not been troubled with bug since. It is also an excellent remedy for scale or other insect pests. This year I intend to syringe a few fruit trees with this substance. With regard to the petroleum I feel sure Mr. Huntley does not mean neat petroleum, even when the sap is up, but it is one of the best insecticides for hard wooded plants when mixed with boiling soap and used carefully. A gardener I knew kept a small bottle of petroleum, and when the vines were in full leaf he placed a spot of the petroleum on every bug he could find. It killed the bug certainly, but when the vines were started the next spring it was found that they were nearly killed, too. *Cautious*.

—The following is a copy of a recipe from the *Gardeners' Year Book* for 1874:—"To destroy mealy bug, Mr. Speed, the able gardener to the Duke of Devonshire at Chatsworth, has furnished us with the following infallible remedy. Take a pint of gas tar and mix with it a pint of dry powdered clay. Form the whole into a paste by adding by degrees a gallon of warm soft water. If this is applied with a brush during winter it effectually destroys mealy bug and indeed all insects, while it does not injure the trees." This recipe is over 30 years old and yet we are still discussing the merits of gas tar as an insecticide. I do not think gas tar or any such crude mixture will give as much satisfaction as the very reliable preparations sent out by the horticultural sundriesmen. A. Prince, *Brockwell Park Gardens*.

—It may be of interest to many readers to have the experience of one who has used gas tar in various forms on fruit trees generally. There can be little doubt but that it is a most effective insecticide, and, when used in moderation, is quite safe to apply to fruit trees. I do not know what *South-East Sussex* means by "diluted," but the form in which I have used it, with very satisfactory results on Plum and

other trees, more with the object of saving the buds than the killing of insects, has been as follows:—Place a quantity of newly-made tar in an old iron pan, about half fill it with tar, and the other half with soft water. Leave this undisturbed for 48 hours. One gallon of the water only (the tar must not be disturbed) should be mixed with four gallons of soft water; and if the trees are syringed with this mixture I do not think birds or insects will visit the trees for some time afterwards. In time, however, the unpleasant smell is lost, and it will then be necessary to make a second application. The tar may be covered with water several times, and must be stirred in order to allow the water to become impregnated with the gases. With regard to Mr. Wilkinson's treatment of vines with tar, I can thoroughly recommend it. I have used it for years past exactly as Mr. Wilkinson recommends. I have also used it mixed with a little clay for the destruction of American aphid, with the best of results. I have also used it on orchard trees to prevent hares and rabbits from eating the bark. On one occasion the man sent to do the work used it in a pure state. They were young trees, and I must confess that I felt anxious as to their condition for some time. However, they came through the ordeal safely, and no mischief whatever resulted to the trees. T. A.

BURBANK'S CRIMSON WINTER RHUBARB.—Amongst the advertisements in a former issue of the *Journal of the Royal Horticultural Society* will be found one, occupying two pages, descriptive of "Burbank's Crimson Winter Rhubarb." The advertiser, after stating that he has "secured an importation of the latest and most valuable vegetable novelty produced by 'the notorious Wizard of the West' and raised in California four years ago," proceeds to give a quotation from the June number of the *World's Work* in praise of his wares. To this I desire to add a postscript, which has a most important bearing upon the identity of the article in question. In the course of a letter published in a later issue of the same magazine Mr. Lloyd, a seedsman of Sydney, N.S.W., states: "In the June issue of your interesting magazine there is a chapter devoted to Mr. Burbank's creations. . . . and there is a statement in the opening paragraph to which I take exception. It is 'only recently the King ordered from him a new variety of Rhubarb. It was obtained by Mr. Burbank from the wild Australian Rhubarb. . . . Now I do not think Mr. Burbank could have stated that he obtained it from the wild Australian Rhubarb, because we do not know of any such, but what we do know is that we supplied Mr. Burbank with seed of a variety which I believe was originated by a grower in Australia, and is known as Topp's Crimson Winter Rhubarb, and is the variety referred to by your contributor. . . . I am under the impression that an English firm include it in their list and call it some special name of their own." I think the case an interesting one, throwing as it does such a strong light upon the origin of this particular "latest and most valuable vegetable novelty." A. G. [Is there a wild Australian Rhubarb? We think not, and we are not aware that Mr. Burbank has ever claimed this variety as his production.—Ed.]

SWEET PEAS (see p. 90).—Mr. Brotherston's experience of the remarkable growth obtained from Sweet Pea plants, when very thinly sown or planted, should encourage other growers to be less free with their seed. It is not until some one bolder than another has the courage to break away from stereotyped methods in sowing seeds, not only of Sweet Peas, but of edible ones also, that the real capacity of strong growers to "branch" and thus become unusually productive is discovered. Only a few days ago a gardener stated that last year he sowed three seeds to a clump instead of the customary 10 or 12, and was astounded at the almost marvellous growth, branching, and fine blooms that resulted. It is by such thin sowing and the consequent free branching growth that our leading vegetable growers obtain their superb samples of Edible Peas and Runner Beans. But in obtaining seed of any of these plants, it is wise to select only the finest for sowing, and even when sown in pots singly, as Mr. Brotherston advises for Sweet Peas, to put out only the strongest plants, and thus is secured at once the finest growth and flowers, and a specially robust strain. A. D.

SOCIETIES.

ROYAL HORTICULTURAL.

FEBRUARY 13.—As is customary every year on the occasion of the annual meeting of this society, a large display of exhibits was made at the meeting held on Tuesday last, and there were numerous Fellows present on the various committees and amongst the visitors.

Orchids were shown well from numerous collections, and the ORCHID COMMITTEE recommended Awards, including one First-Class Certificate and two Awards of Merit.

The FLORAL COMMITTEE recommended Awards of Merit to Kalanchoe Dyeri and Nephrolepis Whitmani.

The chief exhibit before the FRUIT & VEGETABLE COMMITTEE was that of a magnificent group of Orange trees and gathered fruits of varieties of the Orange, and also species of Citrus shown by Messrs. RIVERS.

The annual general meeting of Fellows was held at 3 o'clock in the afternoon. Everything being satisfactory, there was no discussion, and the proceedings lasted for little more than half an hour.

Floral Committee.

Present: W. Marshall, Esq. (chairman), and Messrs. John Green, T. W. Turner, C. R. Fielder, W. Bain, Chas. E. Shea, W. Cuthbertson, W. P. Thompson, E. H. Jenkins, W. J. James, H. B. May, Jas. Walker, Chas. E. Pearson, C. Blick, J. T. Bennett Poë, J. Douglas, S. Reuthe, H. J. Cutbush, Geo. Gordon, Chas. Dixon, Ed. Mawley, Geo. Paul, J. F. McLeod, W. Howe, J. Jennings, N. F. Barnes, and R. Hooper Pearson.

Messrs. SUTTON & SONS, Reading, filled a very long table with named varieties of the florists' Primula, prominent among them being the peerless Duchess and derivative hybrids; His Majesty, with large, double, white flowers; Royal White, and many others, including seedlings in white, blue, crimson, pink, and other shades. The plants were exceptionally well grown, being compact and with bright, healthy foliage. The same firm displayed on an adjacent table a selection of Cyclamen in named varieties. We may mention, as being especially free flowering, the varieties Giant Pink and White Butterfly. (Silver-Gilt Flora Medal.)

Another excellent display of Primula sinensis, totalling nearly 200 plants, was shown by Messrs. H. CANNELL & SONS, Swanley, Kent. The plants were exceptionally robust, and were carrying very large "pips," some being 2 inches in diameter. One of the best varieties in this collection was Mrs. C. F. Raphael, with large inflorescence of rosy-pink coloured flowers of the largest type. There was also the fine white Queen Alexandra, Herbert Bennett (light blue), Mrs. Gregory (a free-flowering, double-pink variety, very useful for cut purposes), Sir F. Fuller (salmon-pink), and many others. (Silver-Gilt Banksian Medal.)

Messrs. JAMES VEITCH & SONS, Ltd., King's Road, Chelsea, exhibited a very pretty assortment of winter-flowering Carnations; miscellaneous greenhouse flowering subjects, including Kalanchoe Dyeri, Primula kewensis X, Astilbe (Spiræa) japonica, remarkably well-flowered; sturdy little plants of white and pink varieties of Azaleas, with a profusion of flowers, Chieranthus kewensis X, &c., and, as a separate exhibit, some interesting early-flowering shrubs, among which we noticed the large-flowered Jasminum primulinum, Loropetalum chinense, Corylopsis paucifolia, a very pretty Forsythia, F. intermedia, Andromeda floribunda, Wistaria, Staphylea, &c. (Silver-Gilt Banksian Medal.)

Mr. H. B. MAY, Dyson's Lane Nurseries, Upper Edmonton, staged a number of well-flowered Azaleas, a selected strain of Primula obconica, and many choice Ferns, including many handsome crested Nephrolepis, such as N. Todeaoides, a variety unsurpassed for its beauty; N. Whitmani (new), N. elegantissima, N. Piersoni, and plants of the less pinnatifid type, of which N. exaltata and N. Fosteri are the best examples. (Silver Banksian Medal.)

Messrs. R. & G. CUTHBERT, Southgate Nurseries, Middlesex, staged a very large number of forced flowering shrubs, including Magnolias, Azaleas, Lilac, Wistarias, ornamental species of Pyrus and Prunus, Daphnes, Spiræa Thun-

bergi, &c., with a setting of Ferns as a ground-work and an edging of Ericas. (Silver-Gilt Flora Medal.)

The largest group in the Hall was a collection of Magnolias, staged by Messrs. WM. CUTBUSH & SONS, Highgate, London, N. A very fine specimen, pyramid trained, of M. Halleana occupied the centre of the exhibit, and there were also tall trees of this variety at either end of the exhibit. Some very well-grown espalier plants of this and other species were prominent, and would be suitable for wall training. The species included the dark red Lenné, speciosa (conspicua), Soulangeana, amabilis and Alexandrina, alba superba, &c. Arranged in a setting of Ferns and small Palms, and relieved with taller Palms at the back, the group was one of much merit. The same firm also displayed seasonable Alpine flowers, and a very pretty collection of Crocuses. (Silver-Gilt Flora Medal.)

Messrs. WM. PAUL & SON, Waltham Cross, Herts, filled the corner adjacent to the east annexe with a group of Camellias, having large plants of the old alba plena—still one of the best white kinds; Reine des fleurs (red), imbricata, &c., at the back, and smaller plants of these and other varieties, such as Corallina, Beauty of Waltham, Tricolor, a single variety with striped petals, Princess Charlotte, &c., in the foreground. (Silver Medal.)

Mr. L. R. RUSSELL, Richmond Nurseries, Richmond, Surrey, showed hardy foliage and flowering shrubs, prominent among them being the new Buddleia asiatica.

Lady TAIT, Park Hill, Streatham (gr. Mr. W. Howe), made a bright display with forced bulbous plants—Tulips, Daffodils, Hyacinths, and Lachenalias. There was a remarkable freshness about this exhibit, and evidence of skill in forcing. The group received the high award of a Silver-Gilt Banksian Medal.

Messrs. J. HILL & SON, Barrowfield Nurseries, Edmonton, had Ferns in variety, a good selection of beautiful kinds, all admirably grown. We have space only to mention a few of the choicer examples, such as Gleichenia flabellata, Polypodium Schneideri, P. iroides, Davallia novae zealandiae, Polypodium quercifolium (a magnificent specimen), Gymnogramme schizophylla gloriosa, &c. (Silver-Gilt Banksian Medal.)

The best plants of Cyclamen seen in the Hall this season were shown by Mr. W. SEWARD, The Beeches, Hanwell, W. The foliage was almost hidden by a wealth of flowers, and the group, viewed from either end, was a carpet of colour. Each plant was a specimen of the best culture, and the strain is one of exceptional merit. (Silver-Gilt Banksian Medal.)

Lord ALDENHAM, Elstree House, Elstree (gr. Mr. Edwin Beckett), displayed a group of Cyclamen, for which he was awarded a Silver Flora Medal.

C. F. RAPHAEL, Esq., Porters Park, Shenley (gr. Mr. A. Grubb), displayed a group of large plants of Souvenir de la Malmaison Carnations of the deep-coloured variety Princess of Wales. The blooms were large and the colour well developed. (Silver Flora Medal.)

Messrs. HUGH LOW & CO., Bush Hill Park Nurseries, Enfield, showed some pretty vases of Carnations, and a mixed collection of indoor flowering plants, among which we noticed many species of Acacia, Euphorbia pulcherrima, Daphnes, the new Nephrolepis Whitmani, and a batch of plants of Dracæna Doucetti, a very ornamental plant, with narrow leaves that are striated and edged with gold. (Bronze Flora Medal.)

Messrs. FELTON & SONS, Florists, Hanover Square, London, showed vases of Carnations, including the beautiful scarlet variety Britannia, one of the best and brightest of this popular flower.

Mr. W. PALMER, Nurseryman, Andover, showed plants of Chinese Primulas, labelled the Andover strain. Some small plants in 60-pots had been specially grown for table decoration. At one end of the group was a batch of Primulas of the stellata type, with blush-white flowers; it was named Queen Alexandra.

Some heavily-flowered plants of Freesia refracta were exhibited by Mrs. B. GREGORY, Shoreham, near Sevenoaks (gr. Mr. Lawrence).

Miss DODGE, Loseley Park, Guildford (gr. Mr. R. Stanard), showed a panicle of fruits of Chamærops Fortunei.

RUBUS BIFLORUS.—This plant, with its long, whitish, wax-covered canes, has been a conspicuous object in these gardens during the winter in the midst of some Camellias and Ericas. This variety was, I believe, brought from the Himalayas, and is by many persons confused with R. leucodermis, a native of Oregon, U.S.A. R. biflorus has much the longer spines, and they are more widely separated than in R. leucodermis. The bark also is very much whiter, and the growths resemble those of a Blackberry, while R. leucodermis has more the appearance of a Raspberry cane. R. phoenicolasius has a rich red-coloured bark, and all three species are exceedingly ornamental in the garden at this season. The fruits of R. biflorus are very pretty in July. These plants grow freely in a moderately heavy soil, which, however, should have a mulching of cow manure applied during the growing season. W. A. Cook.

DAFFODIL "BLINDNESS."—I have more than once stated in the *Gardeners' Chronicle* that "blindness" in Daffodils is a misnomer, but there still exist persons who believe that the flowering spathe is capable of evaporating, or at least vanishing from the bulb, leaving no trace behind. I have also stated that a bulb may be so badly diseased as to be incapable of producing a single root-fibre, yet that same bulb would, provided it contained the traces of the inflorescence within it, produce a scape in the ordinary course. I enclose a bulb for your inspection, which is a poor example, and with no roots developed, yet not only has the flower been produced, but, as you will observe, it is of excellent size and finish, and, more extraordinary still, the leafage is without spot or blemish. From these data I conclude that this diseased-stricken bulb contracted largely of the disease now responsible for the non-production of root-fibres after the rudimentary flower was formed in the early summer of 1906. It is curious and interesting to add that this diseased bulb has produced its flower, &c., much in advance of other bulbs of the same batch that are healthy and well rooted. E. H. Jenkins, Hampton Hill.

ASPIDISTRA PUNCTATA.—This species of Aspidistra has, I believe, become almost ousted from cultivation by its more robust allies, the green and variegated forms of A. lurida. Notwithstanding that it is not quite so vigorous in its habit as A. lurida, it is undoubtedly a plant, owing to the peculiar markings of its leaves, worthy of greater attention. Quite recently I came across three excellent specimens of this particular species growing in a window. The owners had the impression that they possessed quite a new form of Aspidistra. It may be readily characterised by its deep olive-green leaves which are punctuated with white spots. Like all the forms of Aspidistra, it succeeds admirably in a compost of good fibrous loam, leaf-soil, and sand. F. G. Twacher.

APPLE MINCHULL CRAB.—In a district in which I was living some years ago, this variety had evidently at one time been thought much of, as part of an orchard had been planted with it, but subsequently these trees were "headed down" and grafted with Blenheim Pippin and Tom Putt. Although Minchull Crab itself is a good cropper and grower, it had not imparted these qualities to either of the varieties worked upon it, but on the contrary the grafted varieties grew so strongly that few fruits were ever formed, and the trees were ultimately grubbed up. W. H. Clarke, Aston Rowant, Oxon.

NEW INVENTION.

MESSRS. SKINNER, BOARD & CO., of Bristol, have introduced a boiler which is called the "DEFLECTA." They describe it as a multitubular saddle boiler case with a series of chambers in such a manner as to baffle and deflect the flame and heat in passing over the tubes of the boiler. It has the advantages of a tubular boiler without what has hitherto been its great disadvantage, i.e., masonry setting, so that any part can be instantly exposed by detaching the chambers covering the defective part. The series of chambers are rendered smoke-tight by means of faced edges, and to attach these to boiler (which is sent out complete) is a matter occupying but a few minutes. The "DEFLECTA" boiler is practically enveloped by the flame and heat-generated, thus rendering non-conducting covering unnecessary to obtain full power; neither does the temperature of the chambers necessitate covering owing to the baffling of the flame by the tubes of boiler. Great economy in fuel and other advantages are claimed by the patentees.

Mr. A. F. DUTTON, Iver, Bucks, displayed an improved form of the white Mrs. T. W. Lawson Carnation.

Sweet Peas and Carnations formed the subjects of an exhibit staged by Mr. C. ENGELMANN, Horneybrook Nurseries, Saffron Walden, Essex. Mr. G. REUTHE, Keston, Kent, showed several interesting Alpine plants, dwarf Conifers, *Berberis nepalensis*, a great improvement on *B. Mahonia*, to which type it is allied; *Garrya elliptica*, *Daphnes*, &c. (Bronze Flora Medal.)

Sir EDMUND LODER, Bart., Leonardslee, Hortham, Sussex (gr. Mr. W. A. Cook), showed uncommon flowers and shrubs from his interesting garden. A basket of *Sarracenia purpurea* was conspicuous; we also noticed *Grevillea rosmarinifolia*, *Chimonanthus fragrans*, rare species of Hollies, &c. (Silver Banksian Medal.)

Messrs. BARR & SONS, King Street, Covent Garden, W.C., displayed *Narcissi*, and several pretty Alpines. Forced plants of Solomon's Seal—*Polygonatum multiflorum* were interesting; we also noticed the new *Freezia Chapmanii* x.

Mr. ROBERT SYDENHAM, Tenby Street, Birmingham, had pots of forced bulbs grown in moss fibre, with no drainage provided to the receptacles. The plants had flowered well in this material.

Collections of Alpine and hardy plants were shown by Messrs. THOS. S. WARE, LTD., Feltham, who had also Carnations and Primulas. (Bronze Flora Medal); Messrs. JOHN PEED & SONS, West Norwood, including hardy succulent plants, *Primula obconica*, &c.; and the Misses HOPKINS, Barming, near Maidstone, Kent.

AWARDS OF MERIT.

Nephrolepis exaltata var. *Whitmani*.—This variety may be described as between *N. elegantissima*, which was shown last year at the Holland Park exhibition, and *N. Todeoides*, which was illustrated in the supplement to our issue for December 29 last. When fully developed, the fronds are fairly erect, rather spreading, and much less plumose than *N. Todeoides*, the pinnae being shorter and less acute. It should make a good decorative plant. Shown by Mr. H. B. MAY and Messrs. H. Low & Co. (Award of Merit.)

Kalanchoe Dyeri.—This species from British Central Africa was first described in the *Gardeners' Chronicle* for June 4, 1904, p. 354, and the flowers formed the subject of our supplementary illustration to the issue for May 12, 1906. The flowers are white, and the corolla tube about $1\frac{1}{4}$ inch in length. The spread of the segments measures about the same diameter. The plants grow $2\frac{1}{2}$ feet high, or even higher, and the leaves are 8 inches or more long and 5 inches broad. Shown by Messrs. JAS. VEITCH & SONS, Ltd.

Orchid Committee.

Present: J. Gurney Fowler, Esq., in the chair; and Messrs. Jas. O'Brien (hon. sec.), Harry J. Veitch, de B. Crawshaw, W. Bolton, W. Boxall, A. A. McBean, Francis Wellesley, F. M. Ogilvie, F. J. Hanbury, A. A. Peeters, W. H. White, W. H. Young, H. G. Alexander, H. A. Tracey, W. A. Bilney, A. Dye, G. F. Moore, R. G. Thwaites, E. Ashworth, J. Charlesworth, and C. J. Lucas.

There was a fine show of Orchids; several very nice groups were arranged and no fewer than forty-five novelties entered to go before the committee, but only one First Class Certificate and two Awards of Merit were voted.

J. BRADSHAW, Esq., The Grange, Southgate (gr. Mr. Whitelegge), was awarded a Silver-Gilt Flora Medal for a very fine group in which the *Lycastes*, *Odontoglossums*, and white forms of *Cattleya Trianae* were excellent. Of the last-named, *C. Trianae* Emerald and *C. T. Pandora* had fine white flowers with a pale pink tint on the lip. Of the coloured forms, *C. T. Lord Chancellor* was a fine flower of the *C. T. Backhousiana* class. *Odontoglossums* noted were *O. Othello*, of good colour, *O. amabile punctatissimum*, finely spotted with purple; *O. Lambeauianum*, and other hybrids. The best of the varieties of *Lycaste Skinneri* were the varieties *Enchantress*, *alba*, and *Vulcan*; and of hybrids there were a good rosy-red *L. Ballia*, and the fine *L. Imschootiana* variety *amabilis*.

Messrs. CHARLESWORTH & Co., Heaton, Bradford, secured a Silver-Gilt Flora Medal for a very handsome group of principally showy hybrids. The more important things were

arranged in batches of a dozen or so, and the effect was excellent. At one end was a batch of the dark orange-red *Laelio-Cattleya Charlesworthii*, around which were *Brasso-Cattleya Thorntonii*, and a plant of the new *Odontonia Ellwoodii* (*O. cirrosum* x *Miltonia Roezlii*), with a singular, narrow-petalled white flower with a few purple spots on the lip. Next were a clump of fine varieties of *Odontoglossum Rolfeae*; then an arrangement of the handsome *Cattleya Octave Doin*; then a fine set of *Odontoglossum crispum*, including some spotted forms. Beyond were some finely-coloured *Laelio-Cattleya luminosa*, and a further batch of hybrid *Odontoglossums*, and the showy *Cattleya Enid*. Others noted were *Odontodia Bohnhoffiae* and *O. heatonensis*, good *Laelia albida*, and *Miltonia Warszewiczii*.

Messrs. JAS. VEITCH & SONS, Royal Exotic Nursery, King's Road, Chelsea, were awarded a Silver Flora Medal for a neat group of rare and well-grown Orchids, among which were three varieties of their pretty hybrid *Cypripedium Little Gem* (*Harrisianum superbum* x *Baron Schröder*) of fine form and good colour, one of the varieties having the lower sepals enlarged, divided and coloured like the dorsal sepal; *C. Tityus superbum* of the dark rich colour of the best *C. triumphans*; a remarkably good *C.*

[Photo by W. P. Bound.]

FIG. 48.—CÆLOGYNE x COLMANII.
Flowers white, with reddish-orange crest on lip.

Milo, *C. vexillarium* and other *Cypripediums*, *Cattleya Trianae*, &c.

H. S. GOODSON, Esq., Fair Lawn, Putney (gr. Mr. G. E. Day), received a Silver Flora Medal for a good group of *Cypripedium*, *Cattleyas*, *Odontoglossums*, &c., the best of which were *Odontoglossum Othello* var. *Geo. E. Day*, a finely formed yellow flower almost covered with dark chestnut-red blotches; a very handsome dark form of *O. Wilckeanum Goodsoni*; the beautiful *O. loochristiense* *Tracyanum*, which had already gained an Award of Merit; and some excellent hybrid *Cypripediums*.

Messrs. SANDER & SONS, St. Albans, secured a Silver Flora Medal for an effective group, in which were good forms of *Cattleya Trianae*, the variety *exquisita* being white with a slight tinge of lavender colour; a good selection of hybrid *Odontoglossums*, one of the most noteworthy being *O. Wattianum princeps*, a remarkable advance on previous forms in size and colour; *O. Harryano-crispum macrochilum*, with a large shield-shaped labellum; *O. loochristiense nobiliss*, a charmingly-blotched flower; some fine *O. Wilckeanum*, and other hybrids. The *Cypripediums*, which were numerous, included several new forms. Others noted were a good *Laelio-Cattleya* *Henry Greenwood*, some finely-coloured *L.-C. Bletchleyensis*, *Brasso-Cattleya Thorntonii*, &c.

Messrs. JAS. CYPHER & SON, Cheltenham, received a Silver Flora Medal for a fine group of *Cypripediums*, varieties of *Laelia anceps*, *Odontoglossums*, &c., among which of special merit were *Cypripedium aureum virginalis*, and other varieties of *C. aureum*; *C. vill-exul*, *C. Mastersio-exul*, *C. "Transvaal"*, *C. tonso-villosum*, *C. Lathamianum giganteum*, &c.; the group also contained the large and singular *Masdevallia gargantua*, nice plants of *M. Hincksiana*, some pretty *Dendrobiums*, scarlet *Sophranitis*, &c.

Messrs. HUGH LOW & Co. staged a group which included good *Cypripedium aureum* *Surprise*, *C. a. Edippe*, *C. Mrs. Wm. Mostyn*, *C. Euryades enediense*, a large and finely-spotted form; *C. Memoria Jerninghamiae*, a very beautiful hybrid of fine shape; a selection of *Dendrobiums*, *Odontoglossums*, *Cattleyas*, &c. (Silver Banksian Medal.)

Messrs. ARMSTRONG & BROWN, Tunbridge Wells, staged a good selection of hybrid *Cypripediums*, of which specially good were *C. Minos Youngii*, *C. nitens Queen of Yellows*, *C. Juno Orchidhurst* variety, *C. aureum virginalis*, and a very dark form of *C. Fairrianum*. (Silver Banksian Medal.)

Mr. F. G. YOUNG, St. Albans, staged an interesting collection of hybrid *Cypripediums*, several of which were exceptionally pretty. (Silver Banksian Medal.)

R. I. MEASURES, Esq., Camberwell (gr. Mr. Smith), staged a group which included the greenish *Cypripedium venustum Measuresianum*, the fine *C. Leander Cambridge Lodge* variety, *C. Woottonii*, *C. Bryan*, &c.

Messrs. J. & A. MCBEAN, Cooksbridge, were awarded a Silver Banksian Medal and a Cultural Commendation for a pretty little group of the dark scarlet *Epiphrontitis Veitchii*.

FRANCIS WELLESLEY, Esq., Westfield, Woking (gr. Mr. Hopkins), again showed the noble *Cypripedium Aeon giganteum*, the fine *C. Tracyanum*, with a large amount of pure white in the dorsal sepal, and which has already been given an Award of Merit; a fine plant of *C. Ville de Paris* var. *magnifica*, with four massive yellow flowers finely spotted on the dorsal sepal, which has the marginal and upper third pure white; *C. aureo-Spicerianum* and the pretty white-petalled *Cattleya chocoensis* Mrs. Francis Wellesley, which has a yellow disc to the lip and light rose markings.

Messrs. LINDEN, Brussels, showed *Odontoglossum crispum* *Gloire de Moortbeek* and *O. c. Bijou de Moortbeek*, two very fine blotched, home-raised forms; *Odontoglossum auriferum* (*Halli-scanthum* x *crispum*); and *O. crispum* *Prince Carneval*, a good blotched, imported form.

M. A. A. PEETERS, Brussels, showed two fine forms of his beautiful *Odontoglossum Lambeauianum* (for the variety *Idol*, see Awards), and *Cypripedium Leeanum Laekenense*, a large yellow and white, sparsely-spotted form.

Sir FREDERICK WIGAN, Bart., Clare Lawn, East Sheen (gr. Mr. W. H. Young), sent *Cymbidium grandiflorum* and *C. eburneum*, the parents of his good form of *C. Holfordianum*, three nice plants of which were also shown.

M. MERTENS, Mont St. Amand, Ghent, showed several hybrid *Odontoglossums* and *Cypripediums*.

Messrs. J. W. MOORE, Ltd., Rawdon, Leeds, showed a selection in which were *Cypripedium* *Miss Louisa Fowler*, the fine *C. aureum virginalis magnificum*, varieties of *C. Aetæus*, *C. Bassano*, and a pretty, nearly-white form of *C. Mendelii*, with dark rose front to the lip.

Messrs. HEATH & SON, Cheltenham, showed a selection of *Cypripediums*, &c.

H. J. BROMILOW, Esq., Rann Lea, Rainhill, Lancashire (gr. Mr. J. Morgan), showed *Cypripedium Fulshawense Bromilow's* var., a large and well-formed flower.

DE B. CRAWSHAY, Esq., Rosefield, Sevenoaks (gr. Mr. Stables), showed *Laelia anceps* "*Holldayana Theodora*," a very fine, broad-petalled, white form, with violet lines on the side lobes of the lip, and yellow crest; and a good white *Odontoglossum crispum*, which was the first true *crispum* to be raised; also *O. Hunnewellianum* x *O. crispum* "*Raymond Crawshaw*," to prove that even the most promising crosses may not always answer expectation, for this proves to be an indifferent *O. Adriane*.

J. GURNEY FOWLER, Esq., Glebelands, South Woodford, sent *Odontoglossum* "*Othello*" Fowler's variety, a large, cream-white flower, with

innamon-brown blotches, and with purple spotting on the base of the white lip; also *Odontoglossum Lobbi* (amabile x *Pescatorei*), a pretty hybrid near to *O. Lambeanianum*.

Dr. HODGKINSON, The Grange, Wilmslow, sent the dark-coloured *Cypripedium insigne* *McNabianum* in good form.

Mr. JOHN ROBSON, Altrincham, showed *Cypripedium aureum* x *Pomona* and three other hybrids, also a good blotched *Odontoglossum* *rispum*.

F. MENTEITH OGILVIE, Esq., Oxford (gr. Mr. Balmforth), showed a strong specimen of *Cypripedium aureum* *Hyeaunum*.

G. JESSOP, Esq., Rawdon, sent *Cypripedium* *airreanum* "Lucifer," a very good dark form.

HENRY LITTLE, Esq., Baronshalt, Twickenham (gr. Mr. Howard), sent *Odontoglossum* *crissum* Miss Little, a very nice white variety.

AWARDS.

FIRST-CLASS CERTIFICATE.

Odontoglossum Lambeanianum "Idol," from M. A. A. PEETERS, Brussels.—A noble extension of this fine hybrid, two forms of which have already been illustrated in the *Gardeners' Chronicle*. The large, broad-petalled flower was of a rose-coloured ground, heavily blotched with laret. Lip white, with violet blotches at the base.

AWARD OF MERIT.

Odontoglossum venustum "Apollo," from J. BRADSHAW, Esq., Southgate (gr. Mr. White-egge).—A very attractive hybrid, with cream-white flowers blotched with purple.

Calogyne Colmanii (speciosa major x cristata lba), from JEREMIAH COLMAN, Esq. (gr. Mr. W. J. Bound).—A very interesting cross and quite intermediate between the parents. Flowers several on a raceme, large, white, with reddish-range crest on the lip. (See fig. 48, p. 108.)

Fruit and Vegetable Committee.

Present: Geo. Bunyard, Esq. (chairman), and Messrs. Jos. Cheal, Chas. O. Walker, W. Bates, Geo. Woodward, A. Dean, Ed. Beckett, Jas. Gibson, Geo. Kelf, H. Parr, A. R. Allan, W. Wright, R. Lye, H. Markham, W. Fyfe, W. Pope, G. Reynolds, J. Davis, C. G. A. Nix, J. McIndoe, Jno. Lyne, O. Thomas, W. H. Divers, V. Poupart, and A. H. Pearson.

Messrs. J. VEITCH & SONS, Royal Exotic Nurseries, King's Road, Chelsea, exhibited a new ear named "John Seden," raised from a cross between the varieties Bergamotte Esperen and Winter Nelis. The sample had been so conscientiously tested by the committee that we were unable to see a whole fruit afterwards, but we believe that in appearance the seedling somewhat resembles Bergamotte Esperen, and as slightly better flavour.

A fine sample of Chicory came from Miss M. DODGE, Loseley Park, Guildford (gr. Mr. R. Taward).

Messrs. T. RIVERS & SONS, Sawbridgeworth, Herts., displayed a collection of Oranges, both fruits and plants. On former occasions at these meetings Messrs. RIVERS have displayed excellent groups of these fruits, but this time they surpassed all their previous displays, and it was undoubtedly the finest group of any subject in the hall. We have no space to catalogue the many varieties shown, but may state that the variety Achilles had 20 fruits on one branch, and Excelsior as many as 30, which may be taken as a criterion of the splendid culture seen in the exhibit. (Gold Medal.)

About 35 dishes of Apples were shown by O. EARCE SEROCOLD, Esq., Taplow Hill, Taplow (gr. Mr. R. Bullock). Some of the varieties were presented in excellent condition, especially the Golden Apple. There were also good dishes of Blington Pippin, Claygate Pearmain, Baxter's Pearmain, Cox's Orange Pippin, &c. (Silver and Rankian Medal.)

AWARD OF MERIT.

Orange Excelsior.—This variety was selected from Messrs. RIVERS' group for its remarkable cropping qualities and its value as a decorative fruit tree. It is a very old variety, and has been grown at Sawbridgeworth for over 50 years. A small tree in the orangery has 115 fruits, and a branch exhibited had 30 Oranges, any being in clusters of from two to six. It belongs to the St. Michael type, is rather long, oval, and with somewhat thick rind, that is slightly ribbed. Mr. RIVERS informed us that the flavour of the fruits when ripe is very agreeable.

HORTICULTURAL CLUB.

FEBRUARY 12.—The annual general meeting of the members of the club was held at 5 p.m. on Tuesday, at the Hotel Windsor, Westminster, the president, Sir John Llewellyn, Bart., in the chair.

The report stated that there are now 124 members. The papers read at meetings held during the year included "Hybrid Orchids," by Mr. H. J. Chapman; "Parasitism," by Prof. Farmer; "Horticultural and Agricultural Education," by Mr. A. E. Brooke-Hunt; "In the World of Ferns," by Mr. C. T. Drury; "Co-operation," by Mr. T. W. Sanders; and "The Gooseberry Mildew," by Prof. Salmon. The annual outing took place in July, when nearly seventy members and friends visited the gardens at Halton and Tring, by kind invitation of Mr. Alfred de Rothschild and Lord Rothschild. Mr. Harry J. Veitch undertook all the arrangements on that occasion, and the outing proved to be a most enjoyable one. In August the delegates to the Hybridisation Conference were entertained at dinner by the invitation of Sir John Llewellyn. Owing to unusual circumstances, there was a deficit on the year's working of 17s. 9d.

The report was adopted, and the officers and committee re-elected.

The members and friends assembled at six o'clock for the annual dinner. The president, Sir John Llewellyn, presided over a company of sixty-five ladies and gentlemen. Mr. George Paul proposed the toast of "The Royal Horticultural Society," and having been present shortly before at the annual meeting of the Royal Horticultural Society, his speech was one of congratulation. Fortunate, indeed, said Mr. Paul, was a society which had an income of £5,000 a year more than it wanted! There were cries of "No" to this, however, and Mr. Paul then said "more than it has absolute need for." However, he was sure all were delighted to know that the society was so prosperous, and glad that the club had helped the society in various ways in dark days and bright days. They were pleased also to see that the society was putting its large income to good purpose, as was seen in the holding of the Hybridisation Conference, and in the establishment of a research station at Wisley. The society was growing rich, but there were no signs that it was also growing lazy. Mr. W. A. Bilney, in responding to the toast, said that he hoped Wisley would become the "hub" of horticulture in England. In connection with the subject of teaching at Wisley, Mr. Bilney said that at present there were 14 students there, and presently there would be 10 more from the Surrey County Council. At present students remained at Wisley for two years, but he hoped this would be altered to three years, and that part of the time would be spent in France and Germany, to enable them to acquire a knowledge of foreign methods and foreign languages.

The president proposed the toast of the "Horticultural Club." He said it was the daughter of the Royal Horticultural Society, and in entertaining the distinguished foreign visitors in August last, the club discharged one of its greatest duties, that of affording hospitality to eminent visitors to this country. Sir John announced that on March 5 Sir George Watt would deliver a lecture on the "Himalayas," illustrated with lantern slides. Mr. Geo. Monro responded. The toast of the "Visitors" was proposed by Mr. George Bunyard, and responses were made by Col. Prain, Director of the Royal Gardens, Kew, Mr. C. du P. Chiappini, Trade Commissioner to Cape Colony, and Captain P. C. Bam, M.L.G., chairman of the South African Produce Exhibition. Mr. Chiappini said he had only been in England for two days. He had brought 10,000 boxes of fruit with him, and he asked Britishers to help South Africa to right herself. For every box of fruit that arrives here from South Africa, there were twenty boxes of fruit rotting on the trees in South Africa. He wanted his friends here to befriend the fruit when it was placed on the English market. It may be stated here that Mr. Chiappini and Captain Bam have come to this country, as have also, amongst others, Mr. J. Burt-Davy (Transvaal) and Mr. Sim (Natal), in connection with the South African Exhibition to be held shortly in the R.H.S. Hall, Westminster.

The toast of "The Secretary, Mr. Cook," was proposed by the chairman and received with

musical honours. A good programme of vocal and instrumental music was rendered under the direction of Mr. Frank Morrison. Mr. Drury amused everyone present by his original recitation, "A Cheap Dinner."

SCOTTISH HORTICULTURAL ASSOCIATION

THE following extracts are taken from Mr. David Thomson's presidential address. The whole address is so suggestive and so stimulating that we hope it will be published in full and widely circulated.

In my last address I referred to many changes that might take place, and some of them have nearly come about. I think I drew your attention to the fact that the temperature of Stornoway in the month of January, 1906, was higher than it was in the South of France, but this year I find that the temperature of Iceland, a long way north of Stornoway, was higher than it was in many portions of Western and South-western Europe. It was 20 degrees warmer than in Edinburgh and 5 degrees higher than at Nice, and I made a suggestion that the time might come when tourists and invalids in quest of sunshine and warmth, instead of going to what has been termed the Sunny South, would have to come to Edinburgh and Stornoway as health resorts, but now it seems they will have to go still further north at this season of the year to seek the sun.

After alluding to various civic improvements of great local interest, the President continued:

IRELAND.

I paid a visit to Ireland during the past year, and have formed a very different opinion of our neighbouring island than I had done before. I there saw some of the best conducted horticultural establishments I have seen anywhere. I was very much surprised with the magnificence of some of their public parks and the natural beauties of its scenery.

But what struck me most was to see the dreadful state this grand country is getting into. Possessed as it is of the finest soil and the finest climate of any part of the United Kingdom, it is becoming a barren waste, and all this after successive Governments have tried to improve its condition. The land in Ireland that has been given over to the peasantry is going out of cultivation, because the peasants have neither the knowledge nor the means to cultivate it.

So far as I can see the only way to save Ireland is to begin and educate the rising generation, which, under existing circumstances, will be a most difficult matter to accomplish.

Our excursion this year is to visit the Glasgow parks, and there is a great treat in store for all those who have not yet had the privilege of inspecting those parks. There is no town I know of so well supplied with public parks or where gardening, in nearly all its branches, is so ably carried out under great climatic difficulties as it is in the western city.

Since the Mendelian theory has been expounded, many cross-bred and hybrid plants have been developed, which have tendencies that conform pretty definitely to mathematical rules, and this theory has placed the work of plant-breeding, particularly with hybrids, upon a very much more satisfactory basis than it was previously.

There have been some new diseases to record, and the latest of these, the Gooseberry-mildew, which I have already brought under your notice, that threatens to exterminate that fruit. I hope, however, some means will still be found to stay its disastrous progress. I have not heard of its appearance in Scotland as yet, but as I have warned you against it, I hope that if any of you should discover its existence, you will bring the matter before this association.

During the last 12 months there have been several new Acts of Parliament passed, some of which affect horticulturists. I will only mention a few.

Should a gardener fall down the steps of one of those grimy stone-holes I referred to last year, and break his neck, his employer will have to provide for his wife and his family until they can provide for themselves, and should a gardener, while engaged in nailing at the back of a north wall in the winter time miss the head of the nail and hit his finger, which might necessitate the amputation of his hand or arm, the employer will have to provide for him for life, and should a gardener meet with any accident when in the execution of his duties, always assuming, of course, that he is "compos mentis," his employer will be liable in expenses for his support. Another Act now in force ordains that you cannot keep a dog unless you have a collar, with your name and address round his neck, and should he attack a burglar or trespasser, and inflict injuries upon them, the owner must pay the costs.

There is only one more Act which has recently come into force to which I will refer, and it is one that affects us all very closely. It bears an ugly name. It is called "The Prevention of Corruption Act." I suppose you have all heard of this new Act and the terrible penalties that follow on all those who break the law.

The Potato boom has passed away, and the gentlemen engaged in that particular branch of horticulture have got back to their normal condition. The northern star in the firmament above still shines bright to guide the mariner in his trackless path, but the northern star of this hemisphere seems to have sunk into oblivion somewhere in the vicinity of Musselburgh or Inveresk, and the El Dorado is no longer heard of. The "Factor," I am told, has come to stay, but we all know that factors will thrive where others would starve. Potato-growers have now begun to turn their attention to the better cultivation of the older sorts, and I would like to ask if it is not possible to produce a race of Potatoes that will be disease-resisting through inculcation when hybridisation has failed.

The medical profession have found antidotes for many human diseases. They have been able to counteract the ill effects of small pox. They have been able

to find an antidote for hydrophobia, and for many other dire diseases. Can we not find an antidote to the Potato disease and other diseases affecting plant life? Three hundred years of European cultivation have left the Potato plant as tender as ever it was, and one sharp spring frost is sufficient to kill the plants to the ground. And I would here ask our Potato growers if we are cultivating this plant in the proper way? Is it wise to have Potato breadths moulded up as is commonly done? That it is done chiefly to keep the tubers from exposure to light and air is the case, but it still remains a question how far the practice may be detrimental to the robustness of the plant. The method of propagating Potatoes by means of sprouts or cuttings taken from tubers forced into premature growth in warmth under glass has led to its deterioration, and means ruin to the constitution of the Potato.

It would be interesting to note the effects of earthing up and non-earthing up on the Potato. It is not earthed up in its natural state, and if anyone could only produce a Potato that could be used without boiling, a process in which the best of Potatoes are nearly always destroyed, but that could be peeled and eaten like an Apple, he would not only be able to sell it at the fabulous price that some of those now obscure varieties were sold at, but he might even be raised to the Peasage!

NITRIC ACID FROM THE ATMOSPHERE.

Widespread interest and gratification will be aroused amongst agriculturists and horticulturists by the intelligence that a method of extracting nitric acid from the atmosphere has been discovered. This is the latest of a series of recent discoveries which would seem likely to be of the utmost value to agriculturists, who are considerably handicapped by the high price they have now to pay for nitrogenous manure. It is known that in the atmosphere there are practically inexhaustible stores of nitrogen, and this is already being brought into use in two forms of manure, the nitrogen of which is drawn from that source. These manures are, nitrate of lime, made in Norway, and cyanamide of calcium, hailing from Italy and Germany. If the new discovery should lead to the introduction of other forms of nitrogenous manure at more moderate prices, the gain to agriculture may be very great.

I have referred to a few matters outside our association, which I hope may be of interest to you, and I will now come to deal with some of our own affairs.

We have increased our membership, and have consequently increased our revenue from subscriptions.

We have developed our annual flower show, and it is now one of the finest of its kind in the country, but we want still further development.

(To be continued.)

ROYAL GARDENERS' ORPHAN FUND.

FEBRUARY 8.—The annual meeting of the supporters of this charity was held on this date at "Simpson's," Strand. Mr. H. B. May chairman of the Executive Committee, presided, and there were present about the usual number of subscribers.

EXTRACTS FROM THE REPORT OF THE EXECUTIVE COMMITTEE.

The nineteenth annual report of the committee now presented practically concludes the second decade of the fund's existence. Since its foundation, in 1837, the receipts from all sources amount to the grand total of £34,937 9s. 11d., of which sum not less than £16,573 2s. 6d. has been expended in assisting in the maintenance and education of the orphan children of gardeners, and in otherwise helping to give them a start in the battle of life—the special object for which the charity was founded. During the same period of 30 years, investments have been made amounting to over £11,000, yielding a permanent annual income which covers all ordinary working expenses and leaves an acceptable balance to the credit of the fund. The total number of orphans who have been elected to receive the benefits afforded by the charity is 217. At the commencement of the year 90 children were receiving the full allowance of 5s. per week, and to this number 13 were added at the annual meeting, while assistance has been rendered to 19 candidates waiting for election.

The committee again gladly record the fact that the accounts presented show an appreciable increase in the ordinary sources of revenue over the total of the previous year, and their gratification in this respect is greatly enhanced by the knowledge that the increase is largely due to the fact of a greater number of gardeners than heretofore having become subscribers. The expenditure in allowances made to the children during the year shows a slight diminution as compared with the total in 1905, owing to some £25 less having been expended in the item of extra assistance given to children who have ceased to be chargeable to the fund.

The annual dinner, held at the Hotel Cecil on May 10, under the presidency of the treasurer of the Royal Horticultural Society, J. Gurney Fowler, Esq., proved a greater success in every way than any preceding festival, and for the first time in the history of the fund—thanks to the chairman's most appreciative advocacy of the claims of the fund upon all who take pleasure in their gardens—the subscription list amounted to over £1,000.

With the greatest possible pleasure the committee make the announcement that the Rt. Hon. the Lord Mayor, Sir William Treloar, has kindly consented to preside at the next festival, which has been arranged to take place at De Keyser's Royal Hotel, Victoria Embankment, E.C., on Thursday, May 23, and it is sincerely hoped that all supporters of the good cause will assist the committee to their utmost on that occasion to make the presidency of "The Children's Lord Mayor" a memorable event of the year in the horticultural world.

Early in the year the committee received a proposition from the Messrs. C. & W. Bonton, of The Oaks, Herman Hill, Snaresbrook, to place a child of their late gardener on the Fund in consideration of the payment of a lump sum, as provided for by rule 12, but with the stipulation that the child shall be paid the usual allowance of five shillings per week until he is 14 years of age, even though his mother

should marry again in the meantime or not. Desirous at all times of making the Fund as useful as possible, and recognising the generous spirit evinced by the Messrs. Bonton in their desire to benefit the orphan child of a faithful employee, the committee gladly accepted the trust.

The members of the committee who retire by rotation are Mr. John Assbee, Mr. William Bull, Mr. William H. Cutbush, Mr. George Gordon, Mr. J. F. McLeod, Mr. T. A. Morris, Mr. R. Hooper Pearson, and Mr. William R. Upell. To the great regret of all his colleagues, Mr. Morris finds that his business engagements do not permit of his attendance at committee meetings so regularly as he could desire, and on that ground he does not seek re-election, though his fellow workers feel sure that his interest in the Fund will remain as keen as ever. Messrs. Assbee, Bull, Cutbush, Gordon, McLeod, Pearson and Ruppell, all being eligible, offer themselves for re-election. For the seat vacated by Mr. Morris, the committee recommend the election of Mr. David Ingamells, 27, Catherine Street, Covent Garden, W.C.

The balance-sheet showed that the income of the fund during the past year from all sources was £2,573 12s. 2d. (including a balance from the last account of £697 0s. 10d.). A profit of £843 13s. 8d. was made in connection with the holding of the annual dinner in May last. From invested funds, dividends were received amounting to £354 1s. 3d., and from subscriptions and donations (other than those given in connection with the annual dinner), £537 11s. 8d. The following are the principal items on the "expenditure" side:—Allowances to orphans, £1,278 2s. 6d.; grants in aid, £120 7s. 6d.; secretary's salary and clerical assistance, £130; purchase of £114 2s. 5d. 2½ per cent. Consols, £100. The total expenditure, including investments (also balances at bank and on deposit of £771 19s. 8d.) was £2,573 12s. 2d.

The chairman, in moving the adoption of the report, said that it was satisfactory for them to know that in the past twenty years the fund had raised a sum of £34,937 9s. 11d., and that as many as 217 orphans had benefited from their charity. The income continued to increase each year, and he (Mr. H. B. May) was glad to state that some of the increase during the past year was due to the greater amount contributed by gardeners themselves. As showing that there are more subscribers, Mr. May stated that 147 more voting papers were issued this year than last year. The motion for the adoption of the report and balance-sheet having been seconded by Mr. William Marshall, V.M.H., late chairman of the Executive Committee, it was carried unanimously. On the proposition of Mr. Assbee, seconded by Mr. Alderson, Mr. J. Gurney Fowler was elected a vice-president. Mr. Edward Sherwood was re-elected treasurer on the proposition of Mr. Poupart, seconded by Mr. Bull. Mr. Rudolph Barr was re-elected auditor on the proposition of Mr. J. F. McLeod, seconded by the local secretary from Southampton.

The retiring members of the committee were all re-elected, with the exception of Mr. Morris, whose place was filled by the election of Mr. David Ingamells.

The chairman proposed the re-election of Mr. Bryan Wynne, and the motion having been seconded by Mr. W. Bates, it was carried unanimously.

ALTERATION OF RULE.

In accordance with notice, the chairman proposed to alter Rule 4 by omitting the word "secretary" in the fifth line, the alteration being regarded as already overdue, owing to the position of secretary having ceased to be honorary. The motion was adopted without debate.

ELECTION OF ORPHANS.

The following gentlemen having been elected scrutineers of the ballot, the meeting was adjourned until 4.30:—Messrs. Alderson, Cutbush, Cutbush, Howe, McLeod, Pearson, and Poupart. On the meeting reassembling, the chairman announced that one of the candidates was withdrawn from the list owing to the mother having married since the list was drawn up. He declared, therefore, the following candidates duly elected:—

	Votes.
Ivy Constance Warwick ...	408
Nellie Kathleen Wright ...	397
Gertrude Elma Prime ...	363
Annie Violet Claxton ...	356
Jane Laing ...	331
Jno. Edgar Stride ...	310
Edith Fanny Cooper ...	273
Annie Wade ...	249
Herbert Charles Renshaw ...	248
F. B. Gascoigne ...	241
Mary Janet Reid ...	235

	Votes.
M. E. M. Mullens ...	228
C. A. Boyce ...	226
Gladys V. Blackmore ...	174
Amy Tebbutt ...	173
William S. Harrison ...	167

The chairman then said that owing to the retirement of one of the candidates, there were only three upon the list who were unsuccessful, and having regard to the fact that since the close of the year the receipts had been unusually good, and to other circumstances which had happened since the list was drawn up, the committee would be prepared to accept a resolution from the subscribers having for its purpose the election of these also. The resolution having been proposed by the local secretary from Southampton, and seconded by Mr. Harry J. Veitch, the election of Lewis E. A. Tickner, Sarah E. Dudley, and Daisy Ethel Wiggins was carried by acclamation. Thus there were 19 fresh beneficiaries added to the list.

THE FRIENDLY DINNER.

In the evening the committee and a few friends dined together, also at "Simpson's," when Mr. H. B. May presided, and there were about 30 present, including the late chairman, Mr. W. Marshall, V.M.H.

Obituary.

GEORGE MORRISON.—We regret to learn of the death of Mr. George Morrison, for 32 years gardener to Sir George Wombwell, Bart., Newburgh Priory, Yorkshire. After retiring from service in November last deceased went to live with a

THE LATE GEORGE MORRISON

relative at Loch of Liff, near Dundee, where he died on the 8th inst. in his 79th year. He was born in 1828, on the estate of Castle Menzies, in the parish of Ween, Perthshire, and at an early age he was apprenticed to gardening at Scone Palace, the seat of the Earl of Mansfield, near Perth. When quite a young man he came to England, and was later engaged as gardener to Lord Wolverton, in whose service he remained for nearly 30 years. In 1875 he was appointed gardener by Sir George Wombwell. I had the pleasure of knowing the deceased for many years, and also the family whom he served, and it was pleasant to hear how highly the family appreciated their gardener, and how well the latter esteemed his employer. Mr. Morrison was well known as a successful cultivator of fruits. At the York Galas and at various other horticultural shows in the North of England his services were requisitioned as a judge. He was never married. His remains were laid to rest in a sunny spot selected by himself in the beautiful parish churchyard of Liff, on the 11th inst. and were followed by a large company of sorrowing friends. In seeing the grave close over this good old gardener I could not help recalling in my own mind—

Time, like an ever-rolling stream,
Bears all its sons away;
They fly forgotten, as a dream
Dies at the opening day.

—Alex. Innes, Hallyburton, Coupar-Angus, N.B.

JOHN WALLIS.—We are now able to publish a photograph of this esteemed and lamented gardener, whose death was announced in our last issue. He served as a young man for some time under the late Mr. Hill in Keele Gardens, near Newcastle-under-Lyme, Staffordshire. In November, 1872, Mr. Wallis was appointed gardener at Osmaston Manor, Derby, in succession to Mr. Harrison. He only remained at this place for a period of six months, for on the death of his employer, Mr. Wright, the Orchids, stove and greenhouse plants were sold, and there was a general reduction in the establishment. In the same year, or early in 1874, Mr. Wallis was appointed gardener to E. M. Mundy, Esq., at Shipley Hall, Derby, where he remained for six years, during which time he remodelled the gardens and erected a fine range of curvilinear fruit and plant houses.

Mr. Wallis returned to Keele in 1878, and succeeded Mr. William Hill as gardener to the Rev. Walter Sneyd. Mr. Hill, who died in May, 1878, was known all over these islands as a most skilful cultivator of the Grape vine. He won prizes for Grapes at all the important exhibitions, and he occasionally exhibited his fruit on the Continent with equal success. Fruit culture was pursued at Keele by Mr. Wallis with the same ardour as by Mr. Hill, but the vines were cultivated with rather less regard to exhibiting them.

Mr. Wallis made a speciality of Fig-culture, paying much personal care to the trees, and

every shoot should be straightened and the trees be trained perfectly. Many a winter's day was spent in doing this work, but the time was always accorded cheerfully. Pines, Melons, Apricots, Cucumbers, and Tomatoes were grown in considerable numbers under glass, and many Strawberry plants were forced each year. When Mr. Wallis had been at Keele for some years the establishment suffered a severe loss in the death of its owner, the Rev. Walter Sneyd. His son and heir, Mr. Ralph Sneyd, never appeared to regard Keele with much affection as a residence, and eventually the place was leased to the Grand Duke Michael of Russia, the present tenant. Mr. Wallis retired in March, 1899, and has since lived at Woore. He was greatly interested in bees, and knew much of their habits. All who knew the deceased gardener respected him for his conscientiousness. He was straightforward, genial, and kind, and he supported the gardening charities to the best of his ability. For many years he acted as a judge at the Shrewsbury, Wolverhampton, Hanley, and other important exhibitions, and he officiated at Shrewsbury last year. His illness scarcely lasted a week, and it was not until two days before his death that it was thought to be serious. Mr. Wallis married twice. He leaves a widow and seven children to mourn his loss.

LYNCH WHITE, J.P.—We regret to learn of the death, on the 5th inst., at Leigham House, Streatham, S.W., of Mr. Lynch White, J.P., in his 87th year. Mr. Lynch White was the founder of the business which, for many years past, has been carried on as the Thames Bank Iron Company, in Upper Ground Street, S.E., and of which Mr. W. Y. Baker is now the sole proprietor.

MARKETS.

COVENT GARDEN, February 13.

Cut Flowers, &c.: Average Wholesale Prices.

s.d.	s.d.	s.d.	s.d.
Azalea Fielderi, per dozen bunches	4 0-6 0	Marguerites, yellow, doz. bchs.	8 0-4 0

THE LATE JOHN WALLIS.

pruning them always with his own hands. We have never seen better-cultivated and more freely-cropped Fig trees than those at Keele, and for many years they continued to obtain 1st prizes at the Crystal Palace fruit shows. Taking advantage of the ease with which Fig trees may be grafted, Mr. Wallis employed this means to prevent any waste of space through want of young and fruitful growths near to the base of the larger and older trees. Grafts were inserted on the upper side of the main branches, sometimes as many as five or six on one tree, and these fruited very well in the following season, and grew with astonishing vigour. On some of the trees several varieties were thus grafted. Mr. Wallis never stopped any but the very strongest shoots on his Fig trees, preferring to cut out altogether those shoots for which there appeared insufficient space. It was the practice at Keele to employ considerable heat and much moisture in the Fig-house, and, whenever it could be safely done, a little ventilation was left open at the back of the house during all the night. The tree of "Brown Turkey" in the house at Keele at the present time covers a very large space, and has several varieties grafted upon it.

Peach and Nectarine trees under glass were another important feature of the fruit garden at Keele, and those gardeners who, in their younger days, served under Mr. Wallis, will remember how careful he was that

REMARKS.—Alicante and Gros Colmar Grapes are much firmer owing to a short supply, the Alicante being especially scarce. Bananas are dearer and good bunches are a very short supply indeed. Cape fruit is selling readily, and is a little cheaper. Canary Potatoes are a very bad trade. Business generally is quiet. E. H. R., *Covent Garden, Wednesday, February 13, 1907.*

POTATOES.

Bedfords, 65s. to 80s.; Blacklands, 60s. to 70s.; Lincolns, 70s. to 95s.; Yorks, 80s. to 100s.; Dunbars, 80s. to 110s.; Teneriffe, 18s. to 15s. cwt. W. J. C. & S., *Covent Garden, February 13, 1907.*

COVENT GARDEN FLOWER MARKET.

During the past few weeks growers have had no cause to complain, especially in the case of cut flowers. Last season was disastrous as far as Daffodils were concerned, but up to the present time prices have been much better this season, and samples which realised only 4s. per dozen bunches last year have made 9s. this season, and have cleared out well. I find this morning, however, that there is a general drop in prices. Callas, which were making 6s. to 7s. per dozen on Monday last, are down to 4s. this morning; Tulips and Daffodils are cheaper, and it is difficult to forecast even approximate prices for the next week or two. I am afraid growers will be overdone with good cut bloom when it is not wanted, but as Easter falls early, there will be an opportunity of keeping many things until then. It is certain that supplies will be over abundant for the next few weeks. On Monday last the new American Rose Richmond was making 15s. per dozen for special blooms on long stems. This is evidently a Rose with a future. Other good Roses have been making high prices, but a few days of mild weather may make a great difference in supplies. Carnations have been making good prices, but this morning they were cheaper, and it is probable that they will be cheaper still. Gardenias at the end of last week were making 8s. per dozen blooms, a price they have not reached for some years past. Eucharis are more plentiful. Among Orchids Cattleyas have been dear, but Dendrobiums and Cypripediums have not sold well. Double scarlet Pelargonium has been making high prices, and appear likely to do so. The old double white Primula has been selling better lately, and white Azalea (indica) has also realised better prices. We have not quite seen the last of the Chrysanthemums, but they are of poor quality.

POT PLANTS.

Cyclamen and Primula sinensis are both very good. Indian Azaleas are still the leading feature in pot plants, and Dutch bulbous flowers come next, so that Holland and Belgium are responsible for the best supplies of flowering plants just now in Covent Garden. Many foliage plants seen are also from Belgium. Cinerarias are arriving, and with better weather they will be useful. Genistas are more plentiful. In Ericas I have rarely seen better E. Wilmoreana than are to be had. E. persoluta alba is also good, though only brought in as pot plants. I find the florists use this extensively as cut bloom. Hyacinths, Tulips, Marguerites, Begonia Gloire de Lorraine, and Spiraea japonica are well supplied. Growers have not been sending quite such large quantities of foliage plants, but as soon as the weather is more settled the stands will be better filled. A. H., *Covent Garden Market, Wednesday, February 13, 1907.*

THE WEATHER.

THE WEATHER IN WEST HERTS.

Week ending February 13.

A cold and wet week.—The present term of cold weather has now lasted four weeks, during which time there have been only three unseasonably warm days, and but one unseasonably warm night. On the coldest night during the past week the exposed thermometer registered 18° of frost. The ground is now 2° colder than is seasonable, both at 1 and 2 feet deep. Rain, snow, or sleet fell on each of the last five days, and to the total depth of rather more than an inch. These rains have restarted the drainage through the soil gauges, through neither of which had there previously been any measurable percolation for three weeks. The sun shone on an average for 8 hours 40 minutes a day, or for 1 hour 25 minutes a day longer than the average duration for the middle of February. On the brightest day 7 hours 25 minutes of bright sunshine was recorded, which is an exceptionally good record for the time of year. The wind continued on the whole rather high, but in no hour did the mean velocity exceed 14 miles—direction S.S.E. The average amount of moisture in the air at 8 p.m. exceeded a seasonable quantity for that hour by 2 per cent. The winter Aconite first showed an open blossom in my garden on the 11th inst., which is 23 days later than the average date of its first flowering in the same spot during the last 20 years, and later than in any year since 1891, or 16 years. E. M., *Berkhamstead, February 13, 1907.*

TRADE NOTICE.

Mr. S. ASH, for several years Head Gardener to Major-General Hadden, C.B., Rossway, Berkhamstead, has commenced business as a Nurseryman, Seedsman, and Florist, at Church Street Nurseries, Dunstable.

ENQUIRIES AND REPLIES.

CAN any reader recommend small inexpensive books in German or in French relating to, 1, Agriculture, 2, Horticulture, 3, Elementary Botany? L. E. N.

ANSWERS TO CORRESPONDENTS.

* * * The Editor will be glad to receive, for consideration, large photographs of horticultural subjects, suitable for forming Supplementary Illustrations to this Journal.

AMERICAN GOOSEBERRY-MILDEW: D. H. H. You will find an illustration of this disease in our issue for January 19 last, p. 48. A description by Mr. Geo. Massee was published on p. 148 of our issue for August 25, 1900. On page 409, December 15 last, was published the Board of Agriculture's report of this disease, containing information as to symptoms of an attack, and the preventive measures recommended.

CHEMISTRY OF THE PINES: A Thirty Years' Reader. The evergreen trees, including the Pines, absorb the atmospheric air and decompose the carbon dioxide, eliminating the oxygen under the influence of sunlight and fixing the carbon just in the same way as deciduous trees do. They also breathe just as other plants do.

CYANIDING VINES WHEN BREAKING INTO GROWTH: H. S., *Yorkshire*. We have had no experience in cyaniding vines when breaking into growth, but vines have been successfully treated before reaching the flowering stage. Use very small quantities of the cyanide (POISON), and first see that the atmosphere is in a very dry condition and the temperature low. See Mr. Dobson's note p. 85 February 10, 1906. As Muscat of Alexandria is a vine susceptible to injury from fumigation, you should proceed even more cautiously when cyaniding this variety than in the case of the other vines.

EXAMINATIONS: W. Y. Apply to the Science and Art Department, South Kensington, and to the various polytechnics in London.

MIXED FUEL FOR HEATING APPARATUS: E. A. D. D. In our experience in the use of mixed fuel—anthracite, coke and bituminous coal—in the heating of horticultural boilers no harm to boilers has resulted therefrom. Coke and anthracite coal are frequently used together in the heating of horizontal and upright tubular boilers, the former being used the first thing in the morning whenever the temperature happens to be below the desired degree of heat, as it is quicker in action than the anthracite coal, which is used by itself in making up the fire for the night. The burning out of the side of boiler (a wrought iron saddle we presume) at the point where the cold water enters therein through the return pipe near the front of the furnace, is caused through the formation thereon of a calcareous deposit which results from the use of hard water and thereby forms a sort of division between the water and the iron. In some cases this blocks up the water-way, with the result that the iron necessarily burns through in a few years at this point. The injury referred to in your note was certainly not caused through the use of "mixed fuel." The "Economic" horizontal tubular boiler, introduced some 30 years ago by the Thames Bank Iron Company, is constructed with a water jacket fixed over the cradle of boiler, and covering all the top flow-pipes and connected with them. The jacket consists of two 8-inch water-ways one above the other, with a space of 3 inches between to admit of the flame passing between them. In this way the flame that would otherwise be wasted in heating the fire-tile covering of the top of the boiler about 4 inches above the pipes is utilised in heating and furnishing an additional supply of power. This is, in our opinion, a more efficient and economic water-jacket than the one you mention in your note. You might be able to have the sort of water-jacket indicated fixed on to your 9-feet

6-inch horizontal tubular boiler if the work is done during warm weather in summer. Cover your boiler with sufficient sand to form a kind of dome over it, and afterwards cover this with about 2 inches thick of a composition, made by mixing together with water two parts of silver sand and one part cement. This will not only preserve the heat about the boiler, but will also throw off and resist the effects of rain.

NAMES OF FLOWERS, FRUITS AND PLANTS.—We are anxious to oblige correspondents as far as we consistently can, but they must bear in mind that it is no part of our duty to our subscribers to name either flowers or fruits. Such work entails considerable outlay, both of time and money, and cannot be allowed to disorganise the preparations for the weekly issue, or to encroach upon time required for the conduct of the paper. Correspondents should never send more than six plants or fruits at one time: they should be very careful to pack and label them properly, to give every information as to the county the fruits are grown in, and to send ripe, or nearly ripe, specimens which show the character of the variety. By neglecting these precautions correspondents add greatly to our labour, and run the risk of delay and incorrect determinations. Correspondents not answered in one issue are requested to be so good as to consult the following numbers. PLANTS: S. H. We cannot name the specimen from the capsules only; they are those of some Malvaceous plant, probably a species of Hibiscus.—R. J. P. The shrub is not a Daphne but Pittosporum Tobira, the other plant is a Billbergia, probably B. vittata.—F. V. 1, Cyrtomium falcatum; 2, Cestrum fasciculatum; 3, Pteris cretica; 4, Pelargonium, we cannot tell which from a single leaf; 5, Alonsoa incisifolia; 6, Phyllocactus. Why send such abominable specimens?—G. C. W. An ordinary form of Dendrobium nobile.—C. S. Poinciana pulcherrima, from Uganda.—H. G. Lonicera St. Indishii.

NITRATE OF POTASH: J. P. Yours appears to be a good sample, but we cannot undertake its analysis. If you are a member of the Royal Horticultural Society you can have it analysed by the society's chemist at a low fee.

PLANTS FOR GLASS CORRIDOR-HOUSE: J. W. M. There should be no difficulty in keeping your glass-house bright with flowers all the year round, providing you look a season ahead and prepare your plants beforehand. The main batch of Chrysanthemums will be over by the end of December, therefore in January and February bulbs must be chiefly relied upon, including Narcissus, Hyacinths, Tulips, and Lily of the Valley. These might be mixed with Eupatoriums and Marguerites. For March and April there should have been prepared a good batch of Cineraria stellata, and Richardias will also be in full bloom. In May and June "fancy" Pelargoniums and Cytisus racemosus, Coronilla glauca, Rhododendron (Azalea) indicum, with flowering shrubs (hardy), such as Lilacs, Laburnums, Gueldres-Rose, will flower, these being followed by ivy-leaved and zonal-Pelargoniums, Coleus, Fuchsias and Begonias. Annuals cultivated in pots will be decorative in July and August, while Lilliums, early-flowering Chrysanthemums, perennial Asters in pots, and Salvia splendens will keep the house gay during September and October, when the main batch of Chrysanthemums will commence to flower and continue bright until the end of the year. Most of the plants mentioned may be cultivated either out-of-doors or in frames, and upon their careful and proper preparation the results will depend.

RASPBERRIES: J. R. You do not read your *Chronicle* carefully. The information you require was given in our weekly calendar of the Hardy Fruit Garden, on page 39, in our issue for January 19. As yours is not a heavy soil, you should include Superlative in the list of varieties, for this is probably the best all-round variety of Raspberry. Belle de Fontenay and October Yellow are late fruiting varieties.

TWIN-SPATHED CALLA: J. A. B. Richardia africana frequently produces twin-spates under cultivation. Specimens such as that you have sent us are received repeatedly at this office.

THE SPECIES OF THALICTRUM.

HERE are several excellent garden plants among the *Thalictrums* that can be confidently recommended for the ever border, rock garden, waterside and woodland, but there are others wholly unsuited to the garden, being weedy, aggressive, or of botanical interest only. Probably the earliest species to be cultivated is the native *T. flavum*, a plant of some merit, but which is surpassed by at least a dozen species and varieties, some of which are almost unknown to gardeners. The latest arrival—*T. Delavayi*, from China—is a splendid plant whose graceful habit and tiny mauve-coloured flowers appeal most to the artistic sense; it shares, however, with other Asiatic *Thalictrums* the reputation of being somewhat difficult to manage. Several Malayan *Thalictrums*, described as very useful, are not happy in this climate; one does nothing with them, and they ultimately find their way to the rubbish heap, or dead than alive. Those species easy to manage are European and American; they will grow in any well-drained soil, and some of the coarser species can hold their own effectually in competition with grasses and other native vegetation.

Their propagation is effected simply by separating the resting crowns. Another method is to raise plants from seeds, but seeds of the different species, in common with most *Ranunculaceæ*, are naturally slow and irregular in germinating, inasmuch that two years may elapse between germination of the first and the last seedling in one pan containing seeds of one species gathered on the same day, whilst different species from various sources may vary still more.

SPECIES AND VARIETIES.

T. alpinum.—This little plant is the smallest of the genus, and so typically Alpine that one would intuitively plant it in a crack between boulders. It has delicate leafage but 3 inches high, coloured pale green, and is surmounted by dainty panicles of white flowers. It is found on British mountains, and extends northward to the Arctic circle.

T. anemonoides, variously known as *Anemone Thalictroides*, *Rue Anemone*, &c., is a dainty American plant that can only be successfully grown in moist grit and leafsoil at the foot of a rockery slope or at the margin of a pond or brook, where it would get shelter, moisture, and good drainage. It has curious tubercled roots, three-lobed *Adiantum*-like leaves in pretty verticils and panicles of white flowers, that more resemble those of an *Anemone* than of a *Thalictrum*, and which are pure white or pink-tinted, and surrounded by a collarette of leafy bracts. The plant is slender throughout, rarely exceeds a foot in height, and may be described as a marvel of delicate leafage and inflorescence. It blossoms in April, and again in September if the conditions at the root are cool and moist. The plant resembles our native *Wood Anemone* in many respects, and is even more refined and pretty.

T. angustifolium is a sturdy grower that will form a sheaf of pretty leafage 6 feet high overtopped with a foamy mass of pale yellow flowers in plumose panicles. The colouring is derived from the anthers solely, the petals being small and fugitive. It is a capital border plant, whose value lies in its light, airy grace rather than in colour and size of flower.

T. aquilegifolium is a useful and showy border plant that has long been cultivated. The type-plant has yellowish flowers in flattened panicles, consisting mainly of stamens closely aggregated into foamy masses. The stems are hollow, purplish, and are clothed with broad leaves modelled on the lines of those of the *Columbine*. These leaves vary in tint, but are more or less glaucous. Several garden forms have been reared, differing mainly in the colouring of the inflorescence. Of these, the best are album (white), atro-purpureum (dark lilac), lilacinum (pale lilac), and roseum (pale rose). All these forms average 3 feet in height, and, when fully established, are capable of throwing up stems that will give a mass of florescence 2 feet across in June. The species thrives in any soil, but reaches its fullest development in a strong loam, and is of considerable value for grouping by the waterside—the soft tints are just what are required for such a position, and the plant is strong enough to hold its own among the coarsest grasses.

T. Delavayi, from China, is the very best of its race. It is of slender growth, having thin, wiry stems 3 feet high, and slight, airy panicles of mauve-tinted, cupola-shaped flowers, that hang like tiny bells among the *Adiantum*-like leafage. It is more easily grown in a light, moist, sandy soil, and is seen at its best on a rockery slope. Few plants possess the natural grace of *T. Delavayi*. It forms a loose bush, in course of time, that is studded in July and August with hundreds of flowers. The leafage is of value for cutting, being of a deep sage green, with French grey reverse, and one gets a pretty shimmering effect when breezes show the reverse of the leaves and set waving to and fro the tiny tassels of yellow anthers suspending from each mauve dome. It should be planted in spring only. (See fig. 169, December 30, 1905.)

T. flavum, the familiar native meadow Rue, is a useful border plant for bold grouping. A single specimen is too attenuated to be effective, and it is only when forming a group that one can appreciate its true merit. The stems reach 6 feet in height, are sparsely clothed with grey-green, multi-pinnuled leaves, and surrounded by pale yellow panicle flowers, consisting mainly of stamens. It succeeds everywhere—amid shrubs, by the waterside, and in the wild garden. It will thrive in next to no soil, provided it gets plenty of moisture, and it associates well with the subdued colours characteristic of wild English landscape.

T. glaucum.—This plant is a glorified *T. aquilegifolium* with yellow flowers. It is extremely vigorous, and will reach 7 feet in height when established. The root-system covers a square yard, the stems are purplish, and well clothed with glaucous, pinnuled leaves of triangular outline, and they form distinct and imposing features in the plant border throughout summer. The inflorescence is a flattened panicle of soft yellow flowers 2 feet and more across, and when this has finished flowering, numerous subsidiary branches arise from every node of the stem and continue the display. It is a border plant of the first rank. I can recommend it for any position where a bold, imposing plant of refined colouring is required. Custodians of public parks will find it splendid for the decoration of isolated beds, whilst for the waterside, grouped as one would group *Spiræas*, it is very beautiful. *Flavescens*, a paler variety with green, not glaucous, leaves, is a good plant, but lacks many of the distinctive features of the type-plant, and its yellow colouring is reduced to silvery straw-yellow.

T. minus is the familiar *Thalictrum* of wild rocky districts of this country. Its garden value is comparatively slight, but several of its forms find favour for their neat habit and other good features.

Var. adiantifolia.—Practically all the forms of *minus* do duty for this variety from time to time. The true plant does not exceed 18 inches in height. It has minutely pinnuled leaves of a bluish-green tint, and slender panicles of greenish-yellow flowers, with violet-tinted anthers. It is somewhat rare, and is much valued as a rock plant for its pretty habit and diminutive leaves.

Var. elata is grown for its leafage mainly. It reaches 6 feet in height, forming an elegant bush surmounted by a cloud of greenish-yellow flowers in July. Its growths, cut any length, lend elegance to any arrangement of cut flowers, and they will prove useful for table decoration also.

Var. flexuosa is a kindred plant that could be put to similar uses. It has zig-zag stems, and its habit is more lax.

Var. purpurascens grows to 4 feet in height, and has clouds of purplish-tinted flowers that are none too well coloured.

Var. concinna is a dainty little plant of real worth. It has very pretty leafage and greyish-white flowers in clouds. It has the habit, and may be applied to the same uses as *Gypsophila paniculata*.

T. petaloidum.—A very pretty border plant that does not exceed 2 feet in height. It has tuberous roots that fork freely, slender stems in dense thickets, and white flowers in flattened panicles, the petals of which are white, persistent, and comparatively large. Individual flowers have the shape and size of *Anemone narcissiflora*. The wonder is this plant has not been a common inhabitant of gardens years ago. It prefers a light, well-tilled soil, and may be readily increased by simple division. The filaments are flesh-tinted when young.

T. purpurascens, from North America, is a vigorous species that one can recommend for border planting and for informal grouping by the waterside. It grows 6 feet high, and has the stems and leaves of *T. glaucum*—bold, massive, and very handsome. The inflorescence is a dense, drooping mass of purplish flowers 2 feet through, consisting mainly of filaments and sepals. It is a splendid plant—not at all well known, though quite easy to grow.

T. tuberosum is a petaloid species that prefers the drier slopes of the rock garden to the plant border. It rarely exceeds a foot in height. The leaves are marvels of delicate lobing, and the flowers are clustered as in the Rue Anemone, pure white, small in size, but freely produced at midsummer and again in autumn. It is just the plant to form a mass of flower and foliage on the rockwork.

Many other species might be added, but for garden purposes they are not equal to those already described. The Himalayan species alone are worth every effort to grow; they are of the type of *T. Delavayi*, but are even more intractable in our climate. G. B. Mallett.

NEW OR NOTEWORTHY PLANTS.

DISA EQUESTRIS, RICH. F.

THIS pretty *Disa*, described in *Flora*, 1865, p. 181, is flowering for the first time in The Right Hon. Lord Rothschild's gardens, Tring Park, Tring (gr. Mr. A. Dye), on a specimen obtained by the Hon. Walter Rothschild from Rhodesia, and identified, by the courteous assistance of Dr. Rendle, in the Botanical Department of the British Museum of Natural History, South Kensington.

The growth-crown has rather slender, lanceolate leaves about 6 inches in length. The inflorescence, which is about a foot in height, bears on the lower half, at wide intervals, a few

lanceolate leaves, getting smaller towards the flowering portion, where they appear as bracts. The showy part of the flowers consists of a broad, funnel-shaped dorsal sepal, which gradually tapers into a slightly clavate, obtuse, stout, horizontal spur, the whole being about an inch in length and pale-blue to light violet in colour. The less conspicuous organs are the deflexed lower sepals, which are pale violet; and the small white petals, on which is an elongated reddish spot at the tip.

The specimens in the Natural History Museum, marked Salisbury, Rhodesia, show great variation both in the size and number of the flowers on an inflorescence, some of them having forty or more. J. O'B.

ABIES MAGNIFICA VAR. XANTHOCARPA.

THIS superb Silver Fir, like so many others of its race, has had an unfortunate history so far as the names given to it are concerned. We

FIG. 51.—BRACT AND SCALE OF THE SHASTA FIR.
To the left scale with upper part of bract seen in face.
To the right is the scale seen in vertical section, and the bract projecting at right angles.

do not propose to go into this matter now, as we have done so already more than once. The name here used is that which we adopted in the *Hand-list of Conifera* published under the auspices of the late Director of the Royal Gardens, Kew. Nor do we propose at the present time to more than allude to the botanical history of the tree. It may suffice to say that, while some have considered it a form of *nobilis*, others have

FIG. 52.—SCALES, BRACTS, AND SEED OF THE SHASTA FIR.

The bract is incorrectly shown as erect and appressed instead of projecting horizontally: see the right-hand drawing in Fig. 51.

referred it to *magnifica*, and a third made a new species of it under the name *Shastensis*. It is one of those relatively few cases where a vernacular name proves the most convenient. As the Shasta Red Fir it is easily recognisable. So far as cultivated plants are concerned, we first met with the species or variety, whichever it be, in the Cranston Nursery, near Hereford, many

years ago, and since then we do not remember to have seen a cultivated specimen till quite lately, when it was sent us by Mr. J. Crozier, from Durris, Aberdeenshire.

The foliage is like that of *magnifica*, and the shape of the cone also; but in the true *magnifica* the bracts do not protrude. In true *nobilis* the cones are more slender and more elongated, and the bracts are sharply bent downwards. In our present tree, therefore, the distinguishing characteristics reside in the thick, somewhat barrel-shaped cone, and in the bracts that project almost at right angles to the cone. These bracts are of a rich golden-brown colour, and are so striking as to justify our epithet *superb*.

With reference to the direction of the bracts, it may be pointed out that the delineations of the individual scales and bracts, as isolated from the cone are often misleading. What is obvious enough when the whole cone is seen is by no means so apparent when detached or isolated scales are dealt with.

After long study and innumerable comparisons, we had satisfied ourselves as to the distinctness of *nobilis* and *magnifica*, but Mr. Crozier tells us that if we could see the very numerous trees under his charge we should find all kinds of intermediate specimens, to the increased perplexity of the unfortunate student. Only those botanists who have the opportunity of seeing the trees growing in their native habitats can be said to be qualified to give an adequate opinion, and they must study the tree not in one district only, but throughout the whole area in which it grows. It is very probable that many specimens are in the country, but until they produce their splendid cones they are not noticed. M. T. M.

THE ROSARY.

THE NATIONAL ROSE SOCIETY'S ANNUAL.

THIS publication is destined to supply the void left by the discontinuance of the *Rosarian's Year Book*, and to afford timely information of the doings of the National Rose Society. The report and balance-sheet, both very satisfactory documents, have already been commented on: they form the prelude to a sympathetic account of the late Rev. H. H. D'Ombrian, the founder of the society and its secretary for a quarter of a century. Dr. Bernard Dyer's analysis of certain Tea Roses submitted to him is interesting, particularly as showing the relatively large proportion of lime that they contain. Basic slag, which contains lime and phosphorus, may, with advantage, be used in the proportion of 3 to 4 ounces per square yard, whilst nitrogen may be afforded by a dressing of dried blood or fish guano, followed by applications of the nitrate of soda. A good general manure for Roses consists of two parts of dissolved Peruvian guano containing 8 per cent. of ammonia, one part fine bone meal, half part of sulphate of potash, one part of dried blood, half part of nitrate of soda. The whole should be well mixed and applied in early spring at the rate of 5 ounces per square yard. A useful table is given showing the equivalent amounts required per square yard, square rood or perch, rood, and acre respectively. Mr. Mawley's analysis of Roses arranged in statistical form is useful in showing what are the prime favourites at any particular time, and also as indicating the rapid changes in the public taste as regard some varieties, whilst the fickleness of rosarians in some cases is balanced by the persistent favour accorded to other varieties. It is among the last-named that the novice should make his selection.

FRUIT-CULTURE.

WINTER WORK IN FRUIT PLANTATIONS.

PERHAPS a recital of my experience during the present winter will raise some points of interest to growers of fruit, and particularly to growers on a large scale for market.

The beginning was the planting of a field with Apples and Black Currants. The land had been prepared by chalking, ploughing and sub-

there were interruptions; and, if some wise prophet could have foretold the weather of January, there would not have been any resumption of planting until that month had begun. As it was, we had a fair beginning, a somewhat unfavourable middle period, and a good finish.

After all, if Mr. Spencer Pickering's experiments at Woburn, and those which he induced growers to make elsewhere, are to be trusted, the trees planted where the land was wettest

work well. It is a comparatively small and light one, which two horses can draw. Most of these old ploughs are too heavy for a pair of horses. The marking-out of the rows of trees and bushes 6 feet apart each way, was done with a ridging plough without its breast and a marker fixed to it. The stakes were driven in 2 or 3 inches to the north of each cross in a tree row left by the marking plough, and each tree was planted to the south of the stake, small straw

FIG. 53.—THE SHASTA FIR; *ABIES MAGNIFICA*, VAR. *XANTHOCARPA*, A CALIFORNIAN SILVER-FIR.

soiling before the extremely wet weather of November set in, and it was extremely disappointing to have good work neutralised to a great extent by the excessive rainfall. The only consolation was that the downfall showed patches in the field requiring draining, although most of it was drained some years ago; and this requirement was met accordingly. We had no rain worth mentioning from November 20 to December 13, so that a fortnight's fair planting up to the latter date was feasible. Afterwards

ought to grow best. One row was rammed, according to his directions, but not "puddled," as the soil was not wet enough—not being heavy—to churn up into mud. The row of rammed trees, however, is labelled for future observation.

The subsoiling, it should have been mentioned, was done with an old wooden "turn-wrest" plough, without the wrest on. This implement, which may often be bought at a farm-sale in Kent or Sussex for five or six shillings, does the

twists being used when tying the trees, to keep them from chafing against the stakes.

As the trees and bushes are in straight rows, up and down and across, horse cultivation will be possible in both directions for some years. To facilitate this, the trees, although intended to be trained in bush shape, are so trained that they have stems about 3 feet high.

Great inconvenience having been experienced in getting bulky manure on to plantations previously made, through the lack of roadways,

one row in every ten rows, counting both trees and bushes, was omitted for a roadway, which is where bushes would have come in. Thus, between each couple of roadways there are five rows of trees and four of bushes. As the field is a long one of nine acres, there is also a cross roadway through the middle of it, connecting the highway on one side and a farm road towards another highway on the other.

In relation to Black Currants, it may be worth while to mention that an experiment tried in planting part of the field last season has not been repeated. This consisted in the planting of the bushes up to the notches, with the idea that they would throw out more suckers from close to the roots. The results seem to indicate that this was a mistake, probably because the buds just above the roots were buried too deeply. The bushes were cut back severely to make them branch well before they come into bearing, and the trees will be treated in the same way in March or early in April. All the bushes planted this season were raised on the farm from cuttings taken from mite-free Boskoop bushes.

The Apple trees are of several varieties, all budded or grafted on the farm, some on crab-stocks, some on free-stocks, and others on Doucin stocks. Trees on the Paradise do not make enough wood on my land, or at least not on the lighter parts of it.

The reference to raising trees reminds me of the disappointing results of last season's budding, which was the worst for that operation ever experienced since it was first adopted by me. Not only was the drought severe and protracted, but, for some unaccountable reason, it was extremely difficult to find any considerable number of bold and well-ripened buds of many varieties of Apples. Most of the budding was done by myself, and the bark slipped well enough; but the scorching sunshine, day after day, or the poorness of the buds, or both united, rendered failure as common as it had been rare in previous seasons. Plums, budded before the drought got to its worst, succeeded remarkably well, and so did Pears, done later than Apples.

The planting of some thousands of Black Currant-cuttings and some Apple stocks followed the tree and bush planting. The cuttings were made about 8 inches long, and were not disbudded. Why nurserymen usually disbud Black Currant cuttings is a mystery to me. No greater mistake could be made, as the more suckers there are to form branches straight from the roots, the better it is. With red and white Currants the case is different, as they bear on the old wood, and suckers are not wanted; whereas, Black Currants bear chiefly on the new wood, and, consequently, new shoots are wanted from the ground level every year to replace the old ones. The cuttings are planted with about half their length in the soil, so that only five or six buds appear above ground.

Winter pruning is in progress, but is in arrear, in consequence of stress of other work.

A more urgent topic is winter-spraying, and particularly the spraying of Gooseberry bushes, to keep birds from eating the buds. To avoid rendering this article too long, remarks on this subject must be deferred, excepting the prescription for the wash used, which may be immediately useful to some readers. The mixture mainly used this season, while experiments are being tried on a small scale with others, consists of 60 lb. of quicklime, 30 lb. of flowers of sulphur, 12 lb. of caustic soda, and 10 lb. of soft soap to 100 gallons of water. The method of mixing this wash, which is a self-boiling one, is important, in order that the sulphur may be made to combine well with the lime. The sulphur is beaten into a stiff paste, to get all lumps well broken, and is gradually diluted and poured over the lime to slake it. The mixture

should be well stirred while the slaking is going on, and next the caustic soda is added, again stirring until the boiling action has ceased. Then the soft soap, previously dissolved in boiling water or by actually boiling it, is added, and the whole, after another good stirring, and having water added to make up 100 gallons or a multiple thereof, is passed through a fine sieve of brass wire gauze. This mixture is effectual so long as it sticks on the bushes, and nothing yet tried is better than soft soap to make the lime and sulphur adhere to the buds. Somewhat profuse spraying is necessary to coat the bushes well. *A Working Grower.*

MARKET GARDENING.

LILIUM CANDIDUM.

Of late years, in both private and commercial gardens, the culture of this plant has been largely neglected. Its worth, either for its flowers, which are valuable for market purposes, or for the plant itself as a bedding subject and for the embellishment of the conservatory, entitles it to more extended culture. It is surprising how few of these plants are met with, and more especially as they are among the most easily cultivated plants when their requirements are understood. There is no doubt this lack of favour is in a great measure due to the many failures growers have experienced with bulbs procured from seedsmen and dealers. These bulbs are usually imported from the warm climate of the south of France, and are more or less liable to disease, against which there does not at present appear to be any really reliable preventive or remedy. Much of this trouble is caused through the bulbs being imported from such a warm climate, as the bulbs imported from Holland and North Germany are much more successful. Undoubtedly the finest bulbs obtainable, especially for early forcing, are those grown undisturbed for some years in England, and such as are obtained by dealers from small, country cottage-gardens. Another cause of trouble is the drying the bulbs undergo in lifting and transit, for of all bulbs or plants *Lilium candidum* most resents disturbance, and it is better treated as a green plant than as a dry bulb. Another cause of trouble is that many Continental stocks, and more especially the French, are of a different variety to our English, and although many persons would deny it, two distinct types of this plant exist. The less valuable, and the type to be rigorously avoided, is in growth much shorter than the other. The blooms are smaller, not so pure white, and are not so freely produced. The leaves are also much narrower and less numerous on the stem; the bulb can also be easily distinguished, as the scales are much smaller and narrower, while the bulb is inclined to develop a "neck," and is almost identical in shape with that of the old purple Tiger Lilies, *Lilium tigrinum purpureum*, whereas the true English type has very fat, thick scales, and the bulb is perfectly flat on the top, with an entire absence of any neck. This weaker Continental sort is cultivated by exporters in preference, on account of its being more readily obtainable for stock purposes, and also because it can be propagated more quickly and is not so difficult to cultivate. The primary and by far the most important detail to observe in its culture is to not replant oftener than is absolutely necessary. When grown for outdoor decoration, lifting the bulbs once every four or five years is quite often enough, and if the bulbs are cultivated for sale, better returns of large-sized, healthy bulbs will be the result if they are not lifted earlier than the fourth year after planting. August is the proper month to lift them, just after the tuft of new leaves shows above the ground. The bulbs should be planted as soon as possible after lifting and not allowed to become dry. Ample proof of the benefit of

leaving these plants undisturbed may be seen in the exceptional strength and vigour of the clumps found in cottage gardens, where they bloom year after year, producing immense inflorescences, with no trace of exhaustion or disease. The writer has known them to bloom in the same spot for ten years without deterioration. Any good garden soil suits them, but for preference it should be of a light nature and rich in plant food. When planting, dust each bulb with sulphur to prevent attack by the rust and the mildew disease. During the autumn and winter apply a dressing of soot and lime and a mulching of well-rotted manure to the soil, which must always be kept free from weeds.

CULTURE UNDER GLASS.

The cultivation of the plant under glass is more difficult, especially in the case of very early forced bulbs. A very successful method is as follows: Pot the bulbs as they are required for forcing into 8-inch pots. Plunge the pots outside in soil, covering the tops of the receptacles to a depth of 3 inches, and allow the plants to bloom and occupy these quarters for one year, treating them in every respect as though they were planted out in a border. Lift the pots and place them in a glasshouse during the late autumn, and feed judiciously during the whole time of growth. The plunging of the plants outside for a period of one year allows the bulbs to become thoroughly established, and the feeding during their growth under glass compensates for the exhaustion of the plant food in the soil. This soil-exhaustion is not a question of primary importance, as the bulbs will have stored up the greater part of it in their scale-leaves, and this will furnish the energy required to carry them through the second year. There is no doubt but that *Lilium candidum* can be successfully grown in England, and the bulk of the several thousand pounds sterling annually spent on imported bulbs and flowers diverted to our own market growers. *E.C.*

PLANT NOTES.

RUSCUS RACEMOSUS.

THE Alexandrian Laurel is an admirable evergreen plant for mid-winter effect in the garden. It is a green, Bamboo-like plant growing from 4 to 5 feet in height, and succeeds well in a spot that is partially shaded. The wand-like shoots are thickly clothed with small "leaves," and at a distance the plant much resembles a Bamboo. It should be planted in a well-drained soil of a heavy nature, with which has been incorporated some leaf soil and manure.

RUSCUS ACULEATUS

is a suitable plant for covering bare patches under the shade of dense trees. It is a sturdy prickly evergreen, its common name being the Butcher's Broom. In some seasons it develops large red berries, and is then an extremely pretty shrub. This plant is often confused with *Colletia cruciata* (Bictonense), sometimes called the Anchor plant, on account of the woody branches and spines resembling small anchors. It forms a bush 5 to 7 feet in height, and in spring and summer bears a large number of tiny, white fragrant flowers. *W. A. Cook.*

[*C. cruciata* is, as has been shown in our columns, only a form of *C. spinosa*. Both forms have been seen on the same bush. See *Gardeners' Chronicle* Feb. 23, 1878, p. 243, fig. 43. *Ed.*]

TREES AND SHRUBS IN SCOTTISH GARDENS.*

SINCE the middle decades of the last century—the days of the famous Oregon Association and of the collectors W. Lobb and Frey—the gardens of Scotland, and more especially those of Perthshire, have been noted for their collections of Conifers. Certain types of coniferous plants, especially those of West African origin, seem to find there conditions congenial to them than almost any other part of the British Isles or even of Europe. No single garden or locality, I believe, can ever be found to suit all Conifers. Irrespective of hardness, their requirements are too varied for that. But a climate with no great extremes of heat or cold, with abundant moisture, and one never subject to the long intense droughts such as are common in the Thames valley, induces the luxuriant growth of a larger portion of Firs and Spruces than any other part of a climate a considerable portion of Scotland affords.

It is not only Conifers, however, that find congenial conditions there. The extensive coast of the country, the deep inlets of a warm bay, the Gulf Stream and the large amount of mountain, all tend to make the valleys and plains of the western side of Scotland peculiarly adapted for a vegetation which prefers moisture and an equable temperature rather than intense sunlight. The plants of Chili, of New Zealand, of certain parts of Japan and the Himalayas, and of the upland valleys of Northern California are of this type. We consequently find what may at first seem a curious anomaly, many plants are thriving in Ross-shire which would not survive the winter in some of the wine-growing districts of France.

It is, therefore, to a representative group of gardens in Scotland promised to be full of interest and instruction. With the aid of the collector and others acquainted with Scottish gardens, a list of fifteen private places was made, and these I visited during the month of last year.

I also visited the two chief botanic gardens in Scotland—those of Edinburgh and Glasgow. The foundations of an interesting and representative arboretum are being laid in Edinburgh. Prof. Bayley Balfour, but the exposed position and the climatic conditions are, I believe, more favourable to luxuriant tree-growth. A large proportion, at any rate, of the trees are as yet in a comparatively juvenile state. The collection of shrubs, however, is of great richness, especially those belonging to the Heath family such genera as *Erica*, *Bryanthus*, *Enkianthus*, and *Rhododendron*. The great rock garden which is being further enlarged is, moreover, a feature of peculiar interest.

Glasgow, with its atmospheric conditions in the inner gardens and inner parks could scarcely be surpassed. Conifers can hardly be grown at all, even such a tree as the Horse Chestnut is so largely stunted as to be scarcely recognizable.

The Glasgow Corporation, fortunately, under the guidance of Mr. Whitton, pursues a wise and enlightened policy in relation to parks and gardens, and the number of these spaces in the outer ring has greatly increased in recent years. The conditions here are more favourable, and the indoor gardening of some of these newer parks is particularly interesting, especially as regards Orchids and green-house plants. I do not, however, propose to discuss the gardens either at Glasgow or Edinburgh. My object is rather to draw up a few notes on the country places I visited where the cultivation of trees and shrubs is not hampered by adverse conditions. And there I did, indeed, find certain classes of trees, sometimes restricted to small spaces, in the number of species, but represented by such a number of individuals and in magnificent size and vigour as probably no part of the British Isles can show.

MURTHLY CASTLE.

Conifer-lovers in the British Islands have long had for many years been a place of ordinary interest, and it is likely, I think, to remain their Mecca. Remarkable as it is for its Conifers, in no other place, as far as I have seen or heard, do they exist in

quite such magnificent profusion combined with such size, health and vigour. The grounds are situated about 2½ miles out of Dunkeld, on the beautiful slopes of Tayside, and contain about 6 miles of grass walks and avenues mostly bordered with splendid Conifers. There is a very extensive collection of species and varieties, but the dominating tree of Murthly is the Douglas Fir. There are numerous specimens ranging from 80 to over 100 feet high, some of them with trunks more than 10 feet in girth. They are of many shades of colour, ranging from the glaucous green of the Colorado type to the ordinary soft, more grass-like hues. Where they have been planted sufficiently near together to simulate forest conditions they have made magnificent straight, clean trunks of timber. A high opinion is held at Murthly of the durability and value of this timber. I was informed by Mr. Laurie, the gardener, that a gatepost, now in use for 15 years, was still in good condition. Planted singly, with room for lateral development, the fine contour and immense plume-like branches render this tree one of the most ornamental of all Conifers.

Next to the Douglas Firs the most noteworthy of the bigger trees are *Tsuga Mertensiana* (the *Abies Albertiana* of Scottish gardens), *Abies grandis*, *A. nobilis*, and *Picea sitchensis*. *Tsuga Mertensiana*, one of which I made out to be 85 feet high, with its tall, tapering, well-formed trunk, is one of the most beautiful of Conifers, and presents a remarkable difference in habit from its East American ally—*T. canadensis*—of which there is also a fine example 59 feet high, but with a big, rounded, bushy head and a short trunk 8 feet 6 inches in girth. *Abies grandis*, one specimen of which girths 8 feet, grows very quickly here; trees about 20 years old are now 54 feet high. *Abies nobilis*, planted in great numbers, is one of the features of Murthly; the intense glaucous hue of its younger branches and the great crops of cones—large, stiffly upright, and purple—which some trees bear near the top, make it one of the most conspicuous. One specimen I measured was 80 feet high and 7 feet 10 inches in girth. Of *Picea sitchensis* (known often as *Abies Menziesii*) one was 12 feet in girth and, approximately, 100 feet high.

Pinus monticola, of which so high an opinion is used to be held at Murthly, and of which numerous excellent specimens used to grow there, has, in many cases, had to be destroyed on account of the attacks of a destructive pine-rust (*Peridermium* sp.). There is one specimen, however, which, although not quite so fine as the tree at Scone, must still be one of the finest in the country; it is 91 feet high and 6 feet 7 inches in girth.

The glaucous form of *Tsuga Pattoniana*, generally known in gardens as *T. Hookeriana*, is at Murthly the most beautiful of the purely ornamental Conifers. Till one sees it as it is here one can form no adequate idea of its merit. There is one specimen, a pendulous variety, which is the most beautiful Conifer I have seen. It is 54 feet high, the trunk just over 4 feet in girth, and its dense, gracefully pendent, plumose branches are of a silvery glaucous hue. In the sunlight, and in contrast with darker-leaved things around, it made a singularly attractive picture. It was interesting to note that seedlings raised from this pendulous variety have turned out to be true *T. Hookeriana*; they have not inherited the pendulous character of the parent tree, nor have they reverted in the least towards *T. Pattoniana*, of which species, as I have already intimated, *T. Hookeriana* is considered to be merely a glaucous variety. A fine tree of the ordinary *T. Hookeriana* has a trunk of 6 feet 2 inches in girth.

Sequoia gigantea (Wellingtonia), planted in 1867, is now about 90 feet high and 12 feet 2 inches in girth. *Picea ajanensis*, the most beautiful of Japanese Conifers, was 33 feet high, and *P. orientalis* 60 feet high. *Abies Veitchii*, disappointing at present as an ornamental tree on account of its thin habit, was 31 feet high.

Among rarer things were *Juniperus recurva*, the striking Himalayan species, 30 feet high and very well furnished; *Cryptomeria japonica* var. *spiralis*, not remarkable for size but showing the spiral arrangement of the branches particularly well; *Abies sachalinensis*, a very uncommon species, 16 feet high, but here, as

elsewhere, not quite satisfactory; *Picea Omorica*, the Serbian Spruce, and one of the most promising of recent introductions, bearing cones—the first I have heard of in Britain. [We have specimens from Messrs. Paul, of Cheshunt.—Ed.] There was also a healthy young plant of *Pinus pentaphylla*, 4½ feet high; this species is a native of Japan and allied to *P. parviflora*, and the Murthly specimen is one of the very few in the country. In a nursery bed was a healthy batch of about 600 seedlings of *Larix occidentalis*. Some interest is being taken just now in this Larch, a native of Western North America, as a possible substitute for the common Larch. The species is uncommon, and the best trees in the country are probably those in the pinetum at Kew; they are 25 to 30 feet high and bear cones most seasons.

Murthly has some notable Yews. Some of them are between 400 and 500 years old, and have now huge spreading heads. One has a trunk 10 feet 10 inches in circumference at 3 feet from the ground. There is also a huge specimen of the Sweet Chestnut rivaling in bulk the enormous trees at Studley Royal, in Yorkshire. At 5 feet from the ground the trunk measures 24 feet in circumference, and near the ground it is 32 feet; it has, moreover, the remarkable spiral arrangement of the trunk fissures that is occasionally seen in this tree. A specimen at Kew has this character very well marked.

SCONE PALACE.

The long and intimate connection of Scone with the history of Scotland and of the Scottish kings imparts a charm to the place which ancient associations always give. This charm, however, is not always felt so keenly as it is at Scone where thick woods, fine old trees, and spacious lawns are admirably in consort with its romantic history. One of the striking things about Scone, indeed, is the rich and varied character of the woods surrounding the Palace. Mixed with the ordinary deciduous trees of the country, of which there are magnificent old specimens, are numerous fine examples of Douglas Fir, Silver Fir, and other Conifers which give a warm and luxuriant effect. Besides this there is, to horticulturists, the additional although minor interest of its being associated with the early years of David Douglas—one of the first and most famous of plant-collectors. He was born at the village of Scone in 1799 and received his first training as a gardener in the Palace gardens. A notable tree in the grounds is a specimen of Douglas Fir which was one of the original trees introduced by him in 1827 and planted on its present site in 1834. It is now 10 feet 2 inches in girth and only 1 or 2 feet short of 100 feet high.

The collection of Conifers is grown on a piece of ground specially set apart for them. They are planted on well-kept lawns in straight lines, with abundant space for the development of each. The health of the trees is excellent and the general effect imposing and not ill-suited to the formal character of the trees. Perhaps the most notable tree in regard to size in the pinetum at Scone is *Pinus monticola*. This tree in 1891 was 71 feet high; I made it to be now 93 feet high, so that in 15 years it has grown 22 feet; its girth at 4 feet was 7 feet 11 inches. I imagine this to be the finest specimen in Britain. Other fine Pines are *P. ponderosa*, 70 feet high and 7 feet 11 inches girth, and *P. Cembra*, 51 feet high. Of the Silver Firs *Abies Nordmanniana* was 66 feet high and 5 feet 11 inches girth; *A. Pinsapo*, 51 feet high; *A. Lowiana* [concolor] 54 feet high. There was also a beautifully coloured *A. concolor* var. *violacea*, 27 feet high. Of more than ordinary interest to me was a small but healthy young tree of *Abies Mariesii*; this species is exceedingly rare, and the specimen at Scone was the only one I saw in Scotland. The Irish Juniper (*Juniperus communis* var. *fastigiata*) made a column 20 feet high, and a specimen of the common Savin was 10 feet high and covered a space 30 feet in diameter.

Near the Palace are some immense specimens of common trees. A Sycamore (*Acer Pseudoplatanus*) said to have been planted by Mary, Queen of Scots, is still alive but somewhat of a wreck; its trunk, roughly, is about 6 feet in diameter. A gigantic *Populus deltoides*, the North American "Cottonwood," is 15 feet in girth of trunk.

*Contributed to the *Kew Bulletin of Miscellaneous Information*.
Mr. W. J. Bean.

KINFAUNS CASTLE.

The castle of Kinfauns, built on a historic site, occupies a delightful position a few miles out of Perth. It is somewhat elevated above the valley of the River Tay, and behind it rises a magnificent amphitheatre of hills. The gardening here, both indoor and outdoor, is very good; the greenhouses containing for their size a better collection of well-grown plants than I saw elsewhere. The garden is a delightful spot, especially above the house, where it occupies a valley with sloping lawns running down to a brook in the middle and dotted with fine old trees. Conifers are well grown and vigorous, but not many are exceptional in size as these trees go in Perthshire. *Pyrus rotundifolia*, one of the White Beam trees native of Britain but now rare in a wild state, I found here 60 feet high, its trunk 7 feet in circumference. *Quercus Turneri* was 45 feet high—loftier than I have noticed elsewhere, and a specimen of the variegated common Oak was exceptionally well coloured. A fine Sycamore over 100 feet high and a Canadian Hemlock Spruce are also features of the place.

LENY.

Situated about one mile from Callander, and not far from the Trossachs, Leny occupies a position of great natural beauty. To botanists it is a place of more than ordinary interest in being the home of one of the fathers of Indian botany—Francis Buchanan Hamilton (1762-1829). He lived at Leny after he retired from the superintendence of the Botanic Gardens at Calcutta in 1816, and died there 13 years later. Some of the present walks about the grounds were planned and made by him. Leny now belongs to his grandson, Mr. Hamilton Buchanan, chief of the clan Buchanan.

The principal feature of the grounds at Leny is the "glen." This is a picturesque gorge worn out of the face of a steep hill behind the house, down which a burn pursues a rugged and tortuous course. The sides of the glen are in places so precipitous as to necessitate the crossing and recrossing of the stream several times. Along its banks have been planted numerous beautiful trees and shrubs now in luxuriant growth. Perhaps the most noteworthy of these are two Himalayan *Rhododendrons*—*R. barbatum* and *R. Thomsoni*—both of which are now 25 feet high. From their immense size, it is not improbable that they were raised at Leny from seeds sent to Francis Hamilton about 1819 by Wallich, his successor at the Calcutta Botanic Garden. If so, they must be the oldest in the kingdom. Among other things of interest are fine specimens of Canadian Hemlock Spruce—*Tsuga canadensis*—one of which has a trunk 7 feet 2 inches in girth. Another good specimen is growing most picturesquely on the edge of the gorge, whose precipitous side it overhangs, evidence of how much the climate favours the growth of such trees, for its roots appear to be embedded mainly in the rock. *Tsuga Mertensiana*, the common Silver Fir and Douglas Fir, are represented by fine healthy specimens, although not so large as one sees in other parts of Perthshire. Here also is growing what I think is the finest specimen I have seen of the cut-leaved Beech—*Fagus sylvatica* var. *heterophylla*. It has a trunk just over 7 feet in girth and it is 70 feet high.

(To be continued.)

The Week's Work.

PLANTS UNDER GLASS.

By J. G. WESTON, Gardener to H. J. KING, Esq., Eastwell Park, Kent.

The fernery.—Many of the plants in this house are showing signs of growth, therefore re-potting and top-dressing may now be taken in hand. The species of *Nephrolepis* are amongst the earliest, and are very useful Ferns for many purposes, some of the varieties making especially good "basket" plants, being useful also for planting in cork pockets on walls. The old *N. exaltata* thrives almost anywhere, and some of the new varieties are very beautiful, as *N. e. Todeoides*, *N. e. elegantissima*, *N. e. Whitmani*, and *N. e. Pierstonii*. Many of the forms of *Nephrolepis* are strong growers, and require liberal treatment in the shape of feeding, when the pots are filled with roots, also plenty of

water. Ferns cannot possibly remain healthy if neglected in this respect, or if kept in a dry atmosphere. A good many Ferns, usually treated to a stove temperature, might be much healthier, if, after growth was made, they were put under cooler conditions. In potting Ferns, use good, rough, turfy loam and peat, with plenty of rubble, crocks or charcoal, and sufficient sand to keep the soil porous. Pot very firmly.

Any plants that are in bad condition should be washed out and divided, potting the roots first into small pots, and re-potting them as required through the season. If any tree Ferns are in an unhealthy state at the roots, the old ball of roots may be chopped off completely, close to the trunk, the latter then being potted up in some rough compost as above, and put into a warmer house for a time, where they will quickly recover and start to make a healthy growth. Frequent and copious syringings are necessary for all tree Ferns during their season of growth. Any rough Ferns that are not required for pots may be divided and planted under, or by the edges of the stages in plant-houses. These, with *Begonias* of the "Rex" type, and various *Tradescantias* and *Selaginellas* will furnish, in such positions, a quantity of "greenery" for cutting if required. Walls of conservatories or ferneries, furnished with cork pockets or wired frames, may be renewed or filled with a variety of Ferns of a drooping habit; *Woodwardia radicans* succeeds excellently if given sufficient space to develop its beautiful fronds, and many other Ferns will occur to the intending planter, all tending to give an attractive and natural appearance to such houses. *Platyceriums* stand out boldly, and, if well grown, usually attract considerable attention from visitors. After Ferns have been reported, an atmospheric temperature of 60° should be afforded them, admitting a little air on sunny days as the temperature rises, and keeping plenty of moisture about and under the stages, &c. As the sun-heat increases, shading must be given careful attention; the young fronds, being very tender, quickly become yellow if exposed to too much direct sunlight.

FRUITS UNDER GLASS.

By ALEXANDER KIRK, Gardener to J. THOMPSON PATON, Esq., Norwood, Alloa, Clackmannanshire.

The early vinery, in which the Grapes have been thinned for the first time, should have an atmospheric temperature at night of 65°, rising to 75° by day and to 85° if caused by sun heat. Admit a little air by the top ventilators when the weather is favourable, and close the house early in the afternoon. Damp the paths and borders with tepid water daily to maintain much moisture in the atmosphere. Guard against the hot water pipes becoming over-heated, and prevent also draughts of cold, especially frosty air, which would soon cause a check to growth and favour red spider, for the eradication of which pest the syringe would have to be used. Regulate and tie in lateral shoots according to the light and space at command. Do not overcrowd the foliage. Rub out all young growths, pinching sub-laterals at the first leaf. Commence to thin the berries for the second time. Cut out all stoneless berries, and regulate the bunches, which may have been overlooked at the first thinning, by tying up some of the shoulders with small strips of matting. Remove loose, straggly bunches and regulate the crop according to the strength and vigour of the vine. Apply the soil tester to the inside border, and if the soil is found to be dry remove the mulching to one side, and apply to the surface of the border a sprinkling of fine grade vine manure at the rate of 1 lb. to 2 square yards. Next apply a good watering with water at the temperature of 70° and replace the mulching. This watering in general will be sufficient until the berries commence to colour.

Early Figs in pots, which are plunged in a bottom heat of 75°, require an atmospheric temperature of 55° to 60°. When the plants are breaking into growth, increase the atmospheric moisture by damping the paths three or four times daily with tepid water. As the days lengthen increase the heat and give the plants a plentiful supply of tepid water at their roots. Admit air through the top ventilators during favourable weather and close the house early in the afternoon. Permanent Fig trees planted out in borders which have been concreted and pre-

pared for them should be kept cool until the buds swell.

Cucumbers.—Plants that have been in pots during the winter will now be starting into fresh growth. An atmospheric temperature of 65° to 75° by day will be suitable. Damp the paths to keep the atmosphere humid, and syringe the plants if there is any appearance of red spider, &c. Plants raised from seeds sown last month will now be ready to pot on. Place the compost in the pit to become warmed before using it in potting operations. Pots 6 inches in diameter are best. After potting plunge the pots in a bottom heat of 75°, where they may remain until the plants are ready for putting into the border.

PUBLIC PARKS AND GARDENS.

By W. W. PETTIGREW, Superintendent of the Parks and Open Spaces in the City of Cardiff.

Labels and labelling.—The labelling of plants is one of those matters to which every gardener, whether in the "trade" or in private or public service, requires to give more or less attention. In nurseries and private gardens the object of labelling is done merely for the purposes of identification, and such being the case it hardly signifies whether plants are indicated by their proper botanical names or by a system of numbers used as equivalents for these names. On the contrary, in public parks the object is more for educational purposes; hence it is very necessary to furnish, not only the correct scientific name of the plant, but also, where possible, such further information as can readily be presented on a label of ordinary size. There is ample scope for this kind of work in most parks without exactly turning them into botanical gardens. Trees and shrubs, herbaceous plants, and florists' flowers might all, under certain circumstances, be labelled with much advantage to the public. It is surprising and no less gratifying to find the great number of visitors frequenting our parks in these days who take an intelligent interest in all kinds of plants, a circumstance which, taken in conjunction with the fact that the Education Board is doing everything possible to encourage Nature-study among school children, provides a very good reason for extending the practice of labelling plants in public parks. In a town where a park or a portion of one is set aside as a botanical garden, there is hardly the same necessity for extensive labelling in the remaining parks as there would be where no such institution exists.

Kinds of label.—All kinds of materials such as wood, slate, zinc, copper, lead, and gun-metal are used for label-making, and all are more or less useful for the purpose, but the choice of the material and the kind of label employed is as often as not decided simply upon the question of cost. In establishments where a great deal of labelling is done the stamping process is usually adopted, when either rubber stamps are used for printing upon painted labels, or steel stamps upon strips of sheet lead. The latter kind of label, which I first saw used at Kew about a dozen years ago, is difficult to beat for cheapness and general utility, and is the kind I would recommend for use in a public garden. It has been in use from time immemorial.

For trees and shrubs we use a lead label 3½ inches by 3 inches stamped with ½ inch letters filled in with white enamel. In addition to the botanical name, the common one—when known—and an indication of the country to which the plant belongs are given. These labels, attached to a small iron rod, are placed in front of trees and shrubs in such a way that anyone desirous of obtaining their names can easily do so. The labels used for herbaceous plants are 3½ inches by 2 inches, and simply record the botanical name, whilst with florists' flowers only the common name is supplied.

A label-printer.—Labelling is best left in the hands of one man, who should be held responsible for making and printing all labels. Such work is best done during wet weather or the winter time when outside work is at a standstill.

Standard for nomenclature.—As we consider it important in connection with the naming of plants to have a uniformity of nomenclature, we have adopted the *Kew Hand-list* as our guide in that matter.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir Trevor Lawrence Bart., Bursford, Surrey.

Platyclinis.—This genus consists of a small number of species, but all are worth growing, and well bloomed plants are always much admired, especially such an example of *P. glumacea*, as is illustrated in the *Gardeners' Chronicle*, November 9, 1905. Experience has proved that the cool atmosphere of the intermediate house is most suitable for all of the species the whole year round, and when suspended well up to the roof glass in a moderately shady position, and if properly attended to as regards watering, &c., the plants grow well and produce flowers in profusion. *P. glumacea* and its variety *valida* are now producing numerous flowering racemes, and the plants should be liberally supplied with water at the root. *P. uncatata*, whose thread-like racemes are very similar to those of *P. filiformis*, has just gone out of bloom, and the plant should be kept fairly moist at the root until the small growths have attained to their full size. Although *P. filiformis* and *P. Cobbiana* are at rest, they should be kept moist by spraying the foliage overhead, which at the same time will check the increase of red-spider. Any of these plants may be re-potted immediately growth has begun, or as soon as possible after flowering. I find shallow pans are the best receptacles to grow them in, and they will thrive luxuriantly in a thin compost consisting of good fibrous peat, leaf soil, and sphagnum-moss, intermixed with a moderate quantity of small crocks.

Cymbidiums.—Such *Cymbidiums* as *C. Lowianum*, *C. L. concolor*, *C. Lowio-eburneum*, and the reverse cross *C. eburneo-Lowianum*, which are sending up flower spikes, should have abundant supplies of water at the root until the flowers are all open, after which time the compost should be kept just moist. Any plants of *C. Mastersii*, *C. elegans*, *C. affine*, *C. Tracyanum*, *C. Winnianum*, *C. Wilsonii*, *C. giganteum*, *C. Schröderæ*, *C. chloranthum*, *C. madidum*, &c., that require re-potting, should be attended to at once. Being strong rooting plants they require a liberal amount of pot room with good drainage. Afford them a mixture of two-thirds loam, one-third peat, with the addition of small crocks and coarse silver sand. When re-potting, leave a good space below the rim of the pot to hold water, of which these plants require a plentiful supply when well rooted, and all through the growing season. After re-potting water should be afforded in small quantities, gradually increasing the supply as each plant becomes re-established. All of these *Cymbidiums* grow well when elevated upon pots or suitable stands in a light position in the intermediate house, and if their immediate surroundings are kept always thoroughly moist, insect pests rarely infest them, with the exception sometimes of a little brown scale, which is easily eradicated with the brush and sponge.

THE FLOWER GARDEN.

By A. C. BARTLETT, Gardener to Mrs. Ford, Penarrow, Cornwall.

Bedding Pelargoniums.—Cuttings rooted last autumn should now be potted singly or be planted in boxes. Pots should be used for preference, and these must be clean, or at planting time the roots will cling to the pots. Any water that may be necessary should be given on the day previous to potting. If reasonable care is exercised when watering, for a few weeks after the potting is done, no drainage material will be necessary in the pots save a few lumps of loam or some half-decayed leaf-mould. Place the plants in a warm house for a few weeks, and do not afford water until it is really needed; occasional dampings with the syringe on bright days will prevent flagging.

Standard Fuchsias, Heliotropes, &c., should now be trimmed, pruned, and placed in a warm house. As they were potted when taken up from the flower beds, no re-potting will be necessary now, but it will be wise to see that in moving, the soil has not become loosened. Frequent syringings will help the plants to "break" freely and evenly, and as growth advances due attention should be paid to pinching the shoots, so as to ensure the development of well-balanced plants. In these gardens, where often severe autumnal gales prevail, I find old plants unsatisfactory, as the wind often removes large

branches. I insert cuttings towards the end of July, and as soon as they are rooted pot them singly into 3-inch pots, and keep them steadily growing in an intermediate house throughout the winter, pinching the shoots as is necessary. These plants are now in 32-size pots, and will shortly be transferred to 9 and 10-inch pots, when they will be treated similarly to old standards. Such plants withstand rough winds better, and are rather less trouble than old plants which have been used for the purpose previously.

Calceolarias and Violas.—The bedding varieties of these plants in frames, and which were recently pinched, should now be transplanted, using a soil containing a goodly proportion of leaf-soil to ensure their lifting with a good ball of roots when they are finally placed in their flowering quarters. Choose mild weather for the transplanting, keep the frames shut for a few days and cover them with mats at night. After they have recovered, ventilate the frames freely, whenever possible, to promote sturdy growth.

THE KITCHEN GARDEN.

By WILLIAM HONNESS, Gardener to C. COMBE, Esq., Cobham Park, Surrey.

French Beans.—Further sowings of seeds in pots should still be made, but as the outside temperature is becoming higher, these may now be placed in a structure where there is less fire-heat employed. Closer attention will now be necessary to keep the plants free from the attack of thrip and red spider. Sowings might also be made now in boxes for raising plants to plant out in a cool house, or to succeed a crop of Potatoes in a frame. Syon House Prolific and Fulmer's Forcing are two good varieties for these purposes.

Herbs.—In cases where it is considered necessary to replant the beds of the perennial herbs such as Sage, Thyme, Tarragon, Chives, &c., the work should now be undertaken, taking this opportunity to divide the roots. Seeds of such herbs as Basil, Marjoram, &c., which are generally grown, and succeed very well as annuals, should now be sown.

Cabbages.—The Cabbage bed should be thoroughly examined, removing all decayed leaves which, after the severe trial from which they are just emerging, will in many cases be considerable. If a moderate dressing of nitrate of soda can be applied at the present time and well worked into the ground by the use of the hoe, a great improvement in the plants will soon be discernible.

Cropping.—Although the end of February is now near, the weather, at the time of writing, renders the sowing of seeds out of doors impossible, for even on very light soils the ground is much too wet to allow of its being worked. If sowings of Peas and Beans were made in pots and boxes as previously advised, they will in due course prevent a blank that must otherwise have occurred. At the same time, if a piece of ground in a favoured position, or a sheltered border can be found in anything like a favourable condition for working, seeds of either or both of the above-mentioned crops, also of Round Spinach, should be sown.

Tomatos.—Seeds for raising plants to be grown out of doors should now be sown, and another sowing may be made in about ten days' time. As soon as the seedlings are large enough they should be potted into 60-sized (3-inch) pots. The plants will need to be in the best condition for planting at the foot of walls by the end of May, and in the open in the early part of June. By that time they should be thoroughly established in 6-inch pots, and be perfectly "hardened." Last year was an exceptionally good season for Tomatos, and proved that several varieties noted for their prolific qualities indoors, such as Sunrise, &c., were equally free in cropping under outdoor culture.

Tillage.—If not entirely, the greater part of the winter's digging, wheeling, &c., will now be finished, at any rate, in the most prominent parts of the garden, and as the work proceeds, all edgings, whether they consist of tiles, box, &c., should now be given attention. Faulty places and bare patches should be renovated, and all walks in the vicinity that require fresh gravel, or other material to make them good, should be put into good condition; thus giving a fresh appearance to the garden, and a final finish to the rougher work of winter.

THE HARDY FRUIT GARDEN.

By J. MAYNE, Gardener to the Hon. MARK ROLLE, Bicton, East Devon.

Plums.—The pruning and the training of these trees should be completed forthwith. Some varieties of Plums succeed remarkably well grown as standard trees, notably the old Victoria, Jefferson, Pond's Seedling, the Czar, and Denniston's Superb. Bush or pyramid-trained trees also crop freely in favourable seasons providing the centres of the trees are sufficiently pruned to admit air and light and the roots are kept within proper bounds. The true Damsion is not much grown in this county, but it is a desirable fruit. These trees are best grown as standards in a not over-rich soil, as they make growth at the expense of the fruit buds unless somewhat starved. Trees that fruit well should be afforded an annual top-dressing of some manurial material after the prunings have been removed, and few things are better for the purpose than a dressing of wood-ashes, old plaster, or mortar rubble. Barren trees that are growing excessively should have their roots pruned or be transplanted, and then be given a dressing of old lime rubbish, working it well amongst the roots.

Apples.—Bush and pyramid Apple trees are the most profitable. Encourage the roots to grow near the surface of the soil by applying an annual top-dressing of good loam or a mulching of manure, after the pruning is completed, which it should be by the end of this month. Good fruits are produced by horizontally-trained trees, and these are suitable for planting along the margins of walks, but the hard pruning required to keep them within limits is not favourable for an annual average crop of fruits. Bush trees should be allotted a quarter to themselves, and no plants requiring deep cultivation should be allowed near the roots of the trees. Use, however, may be made of the land between the rows when the trees are quite young by planting shallow rooting subjects, such as Violets, Lettuces, or even Gooseberries and Currants.

THE APIARY.

By CHLORIS.

Glossary of common bee terms.—*Artificial swarm*: When a colony has been made by the division of a stock.

Balling: When a new queen is added to a stock the bees cluster over and round her in their attempt to sting her; they are said "to ball" her.

Bee-bread is another name for pollen.

Bee-escape is an appliance by means of which bees may be got out of supers, or even buildings and trees.

Bee-space is a passage wide enough for a bee to pass and one calculated to prevent them building brace combs.

Brood is a term applied to the larvæ of bees, and not, as some imagine, bees after they have emerged from the cells.

Candied honey is honey which has granulated, and may be liquefied by applying heat.

Capped brood consists of the larvæ covered with a thin covering of wax and pollen.

Cappings are the thin coverings of wax which mark the completion of honey stored, so far as each cell is concerned. When they are cut off before extracting honey, they should be stored in a tin vessel with a covering, and then melted later.

Clustering.—When bees swarm or leave a hive they usually settle in some convenient (at least, so far as the bees are concerned) place, and resemble a bunch of Grapes, and they are then said "to cluster."

Comb foundations are thin sheets of wax of varying thickness, according to the purpose for which they are needed, and impressed by machinery with the bases of cells.

Wax is a secretion of the bees, and is formed by them into small scales, which are passed out by them through the eight wax pockets, situated on the under side of the abdomen.

Wedding flight is the flight of a young virgin queen for the purpose of becoming fertilised by the drone. It takes place only once in her lifetime.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the **PUBLISHER**, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the **EDITOR**, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

Illustrations.—The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

APPOINTMENTS FOR MARCH.

SATURDAY, MARCH 2—
Soc. Franç. d'Hort. de Londres meet.
German Gard. Soc. meet.

TUESDAY, MARCH 5—
Roy. Hort. Soc. Coms. meet.
Scottish Hort. Assoc. meet.
Nat. Amat. Gard. Assoc. meet.

THURSDAY, MARCH 7—
Linnean Soc. meet.
Manchester & North of England Orchid Soc. meet.

MONDAY, MARCH 11—
Ann. meet. Unit. Hort. Ben. & Prov. Soc. at R.H. Hall, Westminster.

WEDNESDAY, MARCH 13—
Winter Carnation Soc. Show at Botanic Gardens, Regent's Park.
International Hort. Exhib., Nice, opens.

SATURDAY, MARCH 16—German Gard. Soc. meet.

TUESDAY, MARCH 19—
Roy. Hort. Soc. Coms. meet.
British Gard. Assoc. Ex. Council meet.

THURSDAY, MARCH 21—
Linnean Soc. meet.
Torquay Spring Fl. Show.
Manchester & North of England Orchid Soc. meet.

WEDNESDAY, MARCH 27—Roy. Bot. Soc. Exhibition

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—40°1'.

ACTUAL TEMPERATURES:—
LONDON.—Wednesday, February 20 (6 P.M.): Max. 51°; Min. 37°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, February 21 (10 A.M.): Bar., 30°4'; Temp., 39°; Weather—Cold winds and slight snow.

PROVINCES.—Wednesday, February 20 (6 P.M.): Max. 46° Bury St. Edmunds; Min. 35°; Scotland N.E.

SALES FOR THE ENSUING WEEK.

MONDAY—
Roses, Azaleas, Hardy Plants and Bulbs, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.

WEDNESDAY—
Liliums, Perennials, Border Plants, Hardy Bulbs, Azaleas, Rhododendrons, Palms, &c., at 12.
4,000 Roses, also Fruit Trees, at 1.30 and 4, at 67 & 68, Cheapside, E.C., by Protheroe & Morris.
Plants, Roses, and Lilies, at Steven's Rooms, King Street, Covent Garden, W.C., at 12.30 p.m.

FRIDAY—
Hardy Border Plants, Liliums and other Bulbs, Roses, Azaleas, &c., at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.

Manures and their Use.

The advisability of adding artificially to the supply of plant-food in the soil, by any process of manuring, is to be determined by the ultimate profit to be derived from it. There are few soils that may not be made more productive by the addition of manure in some form or other, and there can be little doubt that most soils demand manuring in order that profitable returns may be realised from them. Whether it will pay to manure with commercial fertilisers is a question for each gardener to determine for himself, according to the particular circumstances in which he is placed.

In the celebrated experiments which have been carried out at Rothamsted, Herts., Wheat has been grown in one portion of a field for 62 years in succession on the same land, without an ounce of manure. In another field Barley has been similarly grown for 54 years in succession, and in yet another field Mangel Wurzul has been grown for 32 years without manure. In some experiments on permanent grass-land, two plots of the land have been left without manure of any kind for 50 years, and yet in the average of seasons they yield 1 ton of Hay per acre. Facts like these, which might be greatly multiplied, serve to show the vast resources of ordinary fertile soils in plant-food, and the inexhaustible supply of gaseous food from the atmosphere aided by the sunlight acting on the green matter of the plant.

In recent years the word exhaustion, when used in connection with the soil, has been given an entirely different meaning to that originally given to it. Now, exhausted soils are understood to be those which no longer produce crops at a profit. The object of manuring is to recoup the soil for waste of all sorts—waste from excessive cropping; waste from drainage due to excessive waterings, either from heavy rain-falls or artificial supplies; waste from the incessant chemical and other changes going on in the soil. To increase the store of plant-food in naturally poor soils, and at the same time to compel them to yield profitable crops, is the problem set before every practical gardener. Fertile soils are rich in the elements of plant-food, and these foods are, through the agency and work of the soil germs or bacteria, being constantly changed and adapted for the use of growing crops.

There is no doubt that many soils can be made to produce crops up to a certain standard, year after year, without the aid of manuring. This is demonstrated in the experiments at Rothamsted, to which we have already referred. This standard of production, however, will rarely meet the requirements of the modern gardener. He must compel the land to do more than it is naturally able to do. To accomplish this he must add to the resources of his soil by applying manure.

Essential conditions for a plentiful supply of vigorous germ-life are a good store of humus or vegetable matter, a well aerated and a well drained and deeply cultivated soil. One of the important objects sought in ploughing, digging, hoeing, and tillage operations generally is to put the soil in such condition that weathering from frost, air, and moisture will go on most rapidly. The crop that follows this cultivation gets the benefit of the provision thus made for it in part only. Do what we will, we shall not be able to utilise all the plant-food that has been prepared for plants in the course of each season's cropping. Some of the nitrogen in the form of ammonia gas escapes from the soil; the nitrates which have combined with lime to form nitrate of lime, and smaller amounts of potash and phosphoric acid, are carried into the soil beyond the reach of the plant rootlets, or are lost in the drainage water.

In a sense, then, cultivation may be said to be a source of waste to the soil, because it is the means of reducing the quantity of humus in the soil; this waste must be made

good by manures. In order, therefore, to keep up the fertility of a garden it is necessary to apply new quantities of nitrogen, either in the form of farmyard or stable manure, peat-moss litter, or vegetable refuse, in order that the store of humus may be replenished. Artificial fertilisers, while they will supply the requisite nitrogen, potash, or phosphoric acid for a crop, will not supply the humus. At the same time, the Rothamsted experiments indicate very clearly that chemical fertilisers applied to suit the wants of soil and crop are not necessarily a source of injury to the soil, but may, indeed, be a lasting benefit to it.

The profits growing out of the use of commercial manures are chiefly dependent upon the cost of the fertiliser and the price of the resultant crop. Like ploughing, digging, or draining, therefore, the use of purchased fertilisers is to be determined by practical economical considerations, and not by chemical or other theories concerning them. Artificial manures have an undoubted position in practical gardening in helping out and reinforcing the natural supply of stable dung, and, even where the home supply is ample, an addition to it of some concentrated manure may often be made of benefit in producing crops "out of season," or by giving some soluble plant-food in the requisite quantity, and at just the best moment to assist the needs of the plant.

Exactly what the soil requires, and how much in the way of artificial fertilisers, cannot be determined by a chemical analysis only. The gardener's special resource is actual trial of the different fertilisers combining the three elements of value in manures—nitrogen, potash, and phosphoric acid. The differences of soils, in respect to fertility, and the variable demands of the many crops in a garden, explain why no hard and fast rule can be laid down for manuring. The gardener who would know what his soil needs must resort to the same means he is accustomed to employ in learning the capacity of his garden in other respects: he must try by actual experiment on a small area of soil the effects of small dressings of sulphate of ammonia, nitrate of soda, kainit, bone-meal, superphosphate, and mixtures of these in measured quantities, and carefully note the results. The information thus obtained will be found of great practical value.

OUR SUPPLEMENTARY ILLUSTRATION is from a photograph of *Cordylina Banksii* in flower in the gardens of Dr. R. HAMILTON RAMSAY, Torquay. Although the species of *Cordylina* are largely used as sub-tropical bedding plants in summer time, they need, in most districts, the protection of a plant house in the winter. In a few favoured spots in our island, such as in Devon, at Torquay, the plants thrive in the open from year to year. An illustration of a seedling plant of *Cordylina indivisa* (vera), and of *Cordylina Banksii* growing in the gardens of Lord ANNESLEY, at Castlewellan, Co. Down, appeared in our issue for October 6, 1906, and is referred to in Dr. RAMSAY's note, who writes as follows: "I was much interested in the fine illustration of *Cordylina indivisa* (vera), grown at Castlewellan, and of *Cordylina Banksii* from the same gardens. I have two fine specimens of *Cordylina Banksii*, grown from cuttings which I obtained in 1890 and which I at once planted out in different parts of my open garden.

Photo by Fred Kitto.

CORDYLINE BANKSII FLOWERING IN DR. HAMILTON RAMSAY'S GARDEN, TORQUAY.

Temple Press Ltd., Printers, 7-15, Rosebery Avenue, London, E.C.

They flower in alternate years. The one of which I send the photograph flowered first in 1902, again in 1904, when the photograph was taken, and again last year. They are planted in sandy loam and leaf mould. The plant illustrated has branched into several stems close to the ground, and is 7 feet in height, with a circumference of 25 feet. The leaves are green with a golden midrib. The specimen has always been out-of-doors since it was first planted in 1890. The plant shows six heads of bloom in the illustration, but last year it had nine inflorescences. I have lately planted several New Zealand and Australian plants in my garden and they are all thriving. They include a lovely tree Fern, *Dicksonia antarctica*. The garden is lovely now (January 1), with Roman Hyacinths, Roses, of which I have still a few, and paper white Narcissus. Bamboos, eight varieties of Palms, including 12 splendid *Trachycarpus* and a lovely tree Fern are in spring-like beauty, and several varieties of *Abutilon* are in flower. Cordyline Banksii when in flower was a splendid sight."

ROYAL HORTICULTURAL SOCIETY.—Exhibitors are requested to notice that on Tuesday, March 5, only the smallest exhibits can be accepted on account of the large amount of fruit, &c., from South Africa. *A. Wilks, Secretary.*

THE SURVEYORS' INSTITUTION.—The next ordinary general meeting will be held on Monday, February 25, 1907, when a paper will be read by Mr. AUBREY J. SPENCER (barrister-at-law), on "The Agricultural Holdings Act (1906)."

THE NATIONAL DAHLIA SOCIETY.—The annual report for the past year has been issued, together with the Schedule of Prizes to be competed for at the great Exhibition of Dahlias at the Crystal Palace on September 5 and 6. The financial statement shows a small balance on the right side, which would have been larger had the Crystal Palace Company fulfilled its obligations. A list of the certificates and other awards made during the year is given. The secretary is Mr. H. L. BROUSSON, Boyton, Foots Cray, Kent.

ORCHID EXHIBITION AT HAARLEM.—The fourth Orchid exhibition of the Dutch Orchidophile Club will be held in the great hall of the Vereeniging Society of Haarlem, from Friday, May 10, to Sunday, May 12, inclusive. The secretary is Jonkheer L. J. QUARLES VAN UFFORD, 8, Van de Spiegelstraat te 's-Gravenhage (The Hague), from whom further information may be obtained.

BELGIAN HORTICULTURISTS.—The *Tribune Horticole* gives a portrait and a sympathetic notice of the late director of the School of Horticulture at Vilvorde, and well known to many visitors to Belgium. A new square at Namur has been called after another Belgian friend, M. FERDINAND KEGELJAN, whose munificence is proverbial at Namur. Together with Messrs. CANNART D' HAMALE, MASSANGE, JEAN LINDEN, EDOUARD MORREN, LOUIS VAN HOUTTE, AMBROSE VERSCHAFFELT, EDWARD PYNAERT, COMTE DE KERCHOVE DE DENTERGHEM, M. KEGELJAN has rendered invaluable services to European horticulture.

THE EXPERT.—We hear of the advent of a new journal to be called *The Expert*. It is for collectors of treasures of every sort from fans to furniture, and including garden ornaments and sundials. The paper is to cost 3d. a week and to issue from 1, Albemarle Street, W.

JAMES BRAIK, whose death is announced in the American papers, was Assistant-Superintendent of the Buffalo City Parks. He was born in Scotland, and served in the 42nd Highlanders (Black Watch). Migrating to America he secured the respect of his associates for his upright character.

THE TWO HUNDREDTH ANNIVERSARY OF THE BIRTH OF LINNAEUS is to be held in May next at Upsala, when Mr. FRANK DARWIN will attend as a representative of the University of Cambridge.

A ROCK GARDEN.—A gigantic piece of artificial rockwork, certainly the highest in Great Britain and probably the highest in the world, is at present in course of construction at Dunfermline, Scotland, the birthplace of ANDREW CARNEGIE, the millionaire. It rises to a height of 100 feet above the stream in Pittencrieff Glen. JAMES BACKHOUSE & SON, Ltd., York, the well-known landscape gardeners and rockwork builders have been engaged upon it over two years, to the order of the managers of the Carnegie trust, who have a large sum at their disposal, the gift of Mr. CARNEGIE, for the improvement of Dunfermline and its surroundings. Large sums are spent by the trust annually in promoting flower shows, extending parks and gardens, &c. *American Florist.*

MONUMENT TO COUNT KERCHOVE DE DENTERGHEM.—It is proposed to erect the monument to the memory of this indefatigable horticulturist and cordial friend, at Ghent, in the square between St. Bavon, the rue de Limbourg and the Banque Nationale. The inauguration will take place at the next quinquennial exhibition, in April, 1908. The centenary of the foundation of the Société Royale d'Agriculture et de Botanique will be celebrated on this occasion. The very handsome manner in which the Ghent society offered its congratulations on the occasion of the centenary of the R.H.S. will not be forgotten. Donations towards the Kerchove memorial may be sent to Dr. MAXWELL MASTERS, 41, Wellington Street, Covent Garden.

OUR KITCHEN GARDEN, &c., by TOM JERROLD. —A second and enlarged edition of this little book is published by Messrs. CHATTO & WINDUS. The several vegetables are dealt with in alphabetical sequence, but we find no mention of Celeriac, or the so-called Chinese Artichokes (*Stachys*). The chief feature of the book consists in its numerous culinary directions. Too little attention is, as a rule, paid to this branch of domestic cookery in small establishments, where Cauliflowers boiled to a smash, and partially-mashed Turnips are the rule rather than the exception. We would suggest, however, that Horseradish for sauce should be pounded as well as grated, until the sauce is made as smooth as the cream itself; that the vinegar for pickling Onions should be boiled with the spice before the jars are filled with it when it cools, and that in nearly all cases Onions are very much better scalded before they are cooked in any form, so as to remove the coarse, acrid flavour nearly all contain.

ARBOR DAY.—We take the following extracts from a letter published in the *Times* from Mr. C. W. RADCLIFFE COOKE:—Arbor Day originated in Nebraska at the instance of the late Hon. J. STERLING MORTON, who was a member of the State Legislature; and, although ridiculed at first, grew so quickly into favour that through its instrumentality Nebraska, once known, from its barrenness and bleakness, as the Great American Desert, became so well afforested as to justify the Legislature in passing a resolution to the effect that thenceforward it should be styled the "Tree Planters' State." Mr. MORTON, who afterwards became Secretary of the United States Department of Agriculture, lived to see the institution he founded encouraged by the Government and adopted and regarded as a general holiday in 40 States and territories. To plant trees in commemoration of public events, distinguished men, or the visits of crowned heads is a custom that goes back to the earliest times in the recorded history of man; and Arbor Day is but an extension of

this custom. Thus, the institution was inaugurated in this country in the picturesque village of Eynsford, in Kent, mainly through the efforts of an energetic resident (Mr. Till) in the year of the Diamond Jubilee of Queen Victoria. In each succeeding year since 1897 Eynsford has had its Arbor Day celebration, in 1900 planting a row of trees in the village street to commemorate the defences of Ladysmith, Kimberley, and Mafeking. Although in some countries the observance of Arbor Day has conduced to afforestation on a great scale, in England, where, with trifling exceptions, all the land is privately owned, operations on Arbor Day must be mostly confined to the planting of trees in the streets of towns, in public parks, and by the road-sides. In order to enlarge the sphere of its influence it has been found essential in England, as, indeed, Mr. MORTON found to be the case in America, to rouse public sympathy and sentiment by making the occasion a public holiday, encouraging school children, as more likely than their elders to see the results of their labours, to take a principal part in the work of tree-planting, and enlivening the proceedings with processions, bands of music, patriotic songs, and social festivities. Conducted on this plan, it is found at Eynsford, and in other places which have followed the example set there, that the effect of the observance of Arbor Day extends beyond the mere occasion; that planting by private persons on their own land is stimulated; that even the school children are so taken with the subject that they will save up their pocket-money to buy a tree each or club together to buy one between them, and in after-life continue to take a keen interest in the preservation, and welfare of the trees they have themselves planted. At the first observance of the institution in this country, at Eynsford, I and Sir GEORGE BIRDWOOD were privileged to assist in the formation of a new orchard by planting a tree of that noted Herefordshire cider Apple the Foxwhelp, and I have lately tasted a bottle of excellent cider made from the fruit of this very orchard; while, to show how after-generations may benefit from the tree-planting tastes of their ancestors, I have now on tap a hogshead of perry, as good of its kind as the cider, made last year from the fruit of Pear trees planted, as documents in my possession attest, in the reign of Queen Anne—giant trees whose gnarled trunks and spreading limbs are not the least attractive features of the landscape. The possibility through the instrumentality of Arbor Day of enlarging the area under fruit ought not to be lost sight of. In some parts of America the State pays to every one who plants and properly cultivates on not more than three acres of land so many rows of trees in the manner prescribed by law a certain sum per acre for the space of five years. Landowners in England often hesitate to supply fruit trees to their tenants on the ground that the latter are apt to neglect them after they are planted. Without wishing to decry the practice of offering prizes for the best collections of table fruit, I think it would be well if some of the prize money now awarded to monstrous Apples and Pears were given, after the American fashion, to the owners of the best planted and best kept orchards. The citizens of Hereford, the latest converts, if I may so style them, to the observance of Arbor Day, propose to beautify the approaches to their ancient city by the planting of avenues. They might, I think, go a step further, and through the influence and popularity of this institution stimulate the planting of fruit trees, for which no kinder soil exists, by private owners and occupiers, and so lead them to follow the "noble example" set in the 17th century, as old John Evelyn records in his *Pomona*, "by Lord Scudamore, of Holme Lacy, near Hereford, and other public-spirited gentlemen in those parts, whereby Herefordshire became in a manner but one entire orchard."

BOTHIES FOR YOUNG GARDENERS.—The following extract from the *Estates Magazine* has our entire sympathy, and is one of those matters which might advantageously be taken up by the British Gardeners' Association. "There are bothies of all kinds fixed in all sorts of places, and whereas in some establishments the comforts of young gardeners are amply catered for by providing them with comfortable and properly lighted and ventilated habitations to live in, the same unfortunately cannot be said about others. I know bothies which are little else than lean-to sheds situated on the north side of a wall and commanding a back-yard view over a coal-shoot or a rubbish heap. In other cases young gardeners are housed in cramped, stuffy dens over store houses, and in one place I know the bothy is next door to a sulphurous stoke-hole. In fact, it is not too much to say that some of the places in which young gardeners are expected to live are unfit for human habitation, and if they were anywhere else besides where they are, they would be condemned as being unsanitary. This is hardly as it should be, and it is a surprising thing in these days that young men can be got to live in such places. Young gardeners do not ask for luxuries, but when apartments are provided for them in lieu of wages, they should be sanitary and comfortable. It is not an exaggeration to say that in some private establishments in the country the horses in the stable are more comfortably housed than the young gardeners in the bothy."

THE ARBORETUM AT TERVUEREN.—This has been formed on land granted for the purpose by the King of the Belgians. It is designed to comprise representatives of the forest vegetation of the temperate zone. Over 200 species are cultivated, 90 being coniferous and 116 broad-leaved, deciduous species, the total number of specimens being about 6,000. Prof. BOMMER, a member of the staff of the Brussels Botanic Garden, has charge of the formation and maintenance of the Arboretum, and has published a descriptive list of the trees arranged first in geographical order and then according to their genera. It forms a useful catalogue, but it is to be regretted that more use was not made, in its compilation, of the report of the Conifer Conference of the Royal Horticultural Society, which is a veritable mine of information on these trees as cultivated in Europe.

DEATH OF A GOOD CULTIVATOR.—In the *Times* appears a notice of the death of Mr. WALTER STRICKLAND, at the age of 74, at his villa at Posilipo, Naples. He inherited the beautiful property upon which he lived and died from his father, and spent his life in cultivating the 22 acres of fruit farm which surround the mansion. By the judicious selection of vines and fruit trees from France and Germany, and by the use of the best modern methods, the property has been rendered the most prolific of any in the neighbourhood—so much so that Mr. STRICKLAND was never allowed to compete for any prize in local competitions on account of its acknowledged superiority. Its commanding site on the top of the point of Posilipo adds greatly to its charm. Mr. STRICKLAND leaves one son, Commander CHARLES STRICKLAND, R.N., now of his Majesty's ship "Implacable."

LETTER FROM KINGSTON, JAMAICA.—The following extracts are made from a private letter received from Mr. WILLIAM J. THOMPSON, who was employed in the 80's at Trentham Gardens, Staffordshire, under the late ZADOK STEVENS, and after passing two years or so in the Royal Gardens, Kew, left Kew to go to a Government appointment in Jamaica, 1889:—"I expect you wonder, if we were all killed in the earthquake of January 14th last. We are thankful that we have escaped as well as we have done. We lost our home, and my wife and little girl were

injured, but I escaped. The rest of the people in our department all escaped without any personal injury, but have sustained a big loss in goods, &c. All the houses and stores in Kingston and suburbs are down; the Governor and friends are camping on the lawns under bamboo and cocoanut fronds. We are well off, as we have a wooden stable to shelter in. Owing to the earthquake and fire there have been about 1,000 people killed, thousands lamed for life, and about £5,000,000 lost. The crops of the country are still with us, unless we get a hurricane to blow them down. Kingston and district is a sad spectacle: churches, schools, houses, and stores all down. The poor people have not suffered much—it is those who were rich; but I am afraid they are now poor. This is a most unfortunate island: if it is not one thing, it is another. For the last two years we had had good seasons, and things were looking bright to all, and now comes this calamity to the island. The 14th January was the day that the West Indian Agricultural Conference opened. The opening took place in Kingston at 11.30—the same day that the shock occurred at about 3.30 p.m. This was the end of the conference, and all the people got off the island as quickly as they could. Sir DANIEL MORRIS and Sir ALFRED JONES escaped, but there were some fine men lost their lives. I was in Kingston at the conference, and only reached home about 15 minutes before the earthquake took place. I was in the garden at the time and saw the King's House buildings fall to pieces—all the place gone. Our home is one of the most complete wrecks there are."

THE SHREWSBURY SHOW.—Now that the Shropshire Horticultural Society's schedule is issued it is seen that not only are all the chief trade and society's classes for collections of vegetables put on a footing of equality, each being for nine dishes, but also that there can be no fewer than 10 first prize collections in the final competition for the champion extra purse of 10 guineas given by the society. The society's old class for 12 dishes is now just on a level with the trade classes, and will consist of nine dishes only, with a splendid first prize of £10. The local or county class is now also for nine dishes. It is stipulated that the champion prize competition shall be judged on a maximum of seven points to each dish basis. It is hoped that these "point" awards will be placed on each competing collection. The work of judging, in this champion class, will be one of exceptional character, even at Shrewsbury. In other matters the schedule appears to be similar to that of last year. It offers the same liberal encouragement to exhibitors of fruit, and exhibitors of flowering and ornamental foliage plants, whilst the classes for cut flowers are very numerous. The total receipts of the society last year amounted to £5,638 15s. 3d., being £409 8s. 4d. in excess of the receipts in 1905. A report of the annual meeting is reproduced on p. 127.

Publications Received.—Monmouthshire Education Committee. *Report of the Director of Agricultural Education*. October, 1906. Arrangements have been made for a course of lectures on agriculture and horticulture to be given at the Usk Higher Grade School, Little Mill Reformatory, Rumney, and Llanfrechfa Lower.—U.S. Department of Agriculture, Farmers' Bulletin, 275. *The Gipsy Moth, and how to control it*, by L. O. Howard.—Bulletin No. 63. *Papers on the Cotton Boll Weevil and Related and Associated Insects*, by A. W. Morrill.—Lancaster County Council, Education Committee, Agricultural Department, Farmer's Bulletin No. 2.—*Report on Experiment on Manuring Rye-grass and Clover*, by Edward Porter and R. C. Gaut.—*Agricultural Journal of the Cape of Good Hope*, January. Contents: Citrus in Albany and Bathurst, Rural Cape Colony (Wellington); Harvesting Competition, Khaki Bush, &c.

THE CORDYLINES.

(See fig. 54, also Supplementary Illustration.)

CORDYLINA AUSTRALIS, better known as *Dracæna australis*, is a very common plant in the south-west. In every town in South Devon and Cornwall the plants are to be seen on every side, and in Torquay, alone, some thousands must be planted, as considerably over a hundred fine specimens are in evidence in the public gardens, and they are also present in almost all private grounds. In the summer they present a beautiful sight, as almost every example blooms, and the great, branching flower-sprays, 3 feet or more in length, crowded with white blossoms, resemble huge plumes. They are sweetly-perfumed, and are all day visited by innumerable insects and butterflies. In the type the leaves are narrow, but the seedlings, which are raised in quantity in the south-west, vary greatly in their foliage, the leaves in some cases being fully 3 inches in breadth. These wide-leaved forms are far handsomer than the type. *Cordylina australis* is considered perfectly hardy in Devon and Cornwall, but two years ago 17 degrees of frost in November, followed by a day of brilliant sunshine, ruined some specimens in the neighbourhood of Plymouth. The tops of these plants were absolutely killed, but they eventually developed a number of new growths from the base.

There are many splendid examples of *Cordylina australis* in the south-west, but the finest known to me is the one illustrated at fig. 54. It is growing in the gardens at Enys, and is 20 feet in height, with a trunk circumference of 6 feet, at 1 foot from the ground. A short distance above the ground level the plant divides into four main branches, which are subdivided into about 30 "heads," about 10 of which generally flower annually. This specimen is 47 years old, and was raised from seed sent from Australia.

C. indivisa, shown in the foreground of fig. 54, is very distinct from *C. australis*, though often confounded with it, and illustrations of *C. australis* have repeatedly appeared above the title of *C. indivisa*, while in many gardens *C. australis* is still grown under the latter name. *C. indivisa* is a native of New Zealand, where it grows at a considerable altitude. The leaves are very handsome, being about 5 feet in length and 5 inches in breadth, blue-grey in colour, with a midrib of bright red. It has, I believe, only flowered once in the British Isles, this being in the Tresco Abbey gardens, Isles of Scilly, in 1895. The flower-shoot is pendent, and is composed of countless, minute blossoms, the spike, yellow and blue-black in colour, being more curious than beautiful. It is a rare plant, but there are a dozen or more specimens in Cornwall, the finest of which is probably one at Enys (not the specimen shown in fig. 54), which is 10 feet in height.

C. Banksii is also a native of New Zealand, and is easily distinguished from either of the above-named species. It is of moderate growth, and rarely attains a greater height than 6 feet, and is generally clothed; to the ground level, with arching leaves 4 inches in breadth. The branchlets of its flower-spikes are far fewer than those of *C. australis*, so that the white-blossomed panicles are lighter in appearance. An excellent supplementary illustration of *C. Banksii* appeared in Vol. xxix., page 44, and a representation of a specimen at Castlewellan on October 6, 1906. *Cordylina Banksii erythrorhachis* is a variety with bright red midribs to the leaves. This is to be found in at least one Cornish garden, and the type is fairly well represented in the county. *C. Hookeri*, *C. Doucetti*, and *C. Prince Albert* appear to be forms of *C. indivisa*. *C. lentiginosa* is of similar habit to *C. indivisa*, its leaves, when young, being yellowish, and subsequently turning to deep bronze-brown. *S. W. Fitzherbert, Kingswear, Devon.*

GALLOWAY HOUSE, WIGTOWN-SHIRE.

DURING a visit to the ancient and historical burgh of Wigtown in October last I had the privilege of seeing for the first time the famous grounds and gardens of Galloway House. This imposing residence of the Earl of Galloway, which, as the people in the neighbourhood proudly assert, "has windows for every day in

The cultivation of fruit has always been made a great speciality at Galloway House, a fact sufficiently illustrated and emphasised by Mr. Day's successes at the leading British exhibitions.

At Galloway House the Muscat Grapes, so attractive alike in their exquisite amber colour and delicious flavour, are largely grown. Such fine varieties as Muscat of Alexandria, Muscat Hamburg, Madresfield Court, and Mrs. Pince,

and is well represented by four large trees, one of which has an extension of branches upwards of 30 feet in area, as well as by many graceful cordons in various positions and aspects, all of which, in favourable seasons, bear abundantly. Plums, such as Jefferson's, Lawson's Golden Gage, Kirk's Seedling, and Coe's Golden Drop are very largely grown. Most of the Gages have a southern or western aspect, while the Czar, Early Orleans, Belgian Purple, Early Prolific, Deniston's Superb and Victoria are found to succeed equally on walls facing east. Mr. Day finds that the Victoria variety, which is of all Plums the most universally popular, succeeds well on walls with a northern aspect.

It is only in fine dry autumnal seasons that the thorough maturation of Figs can be attained in this locality. At Galloway House, where their culture under such conditions is generally successful, Castle Kennedy and Brunswick are among the most reliable and prolific varieties.

The finest herbaceous flowers, such as Francoa appendiculata and the great American Lobelia (cardinalis), survive adverse winter visitations and experiences in these gardens, with an inconsiderable amount of protection. Montbretia Germanica is very effective; so also is the eminently beautiful Sparaxis pulcherrima, a special favourite of Sir Herbert Maxwell, which he grows grandly at Monreith. Crinum Moorei, Mr. Day informs me, flowers with facility in sheltered situations, its soft pink blossoms being greatly admired. Roses of every free-flowering description are cultivated effectively; especially luxuriant are such varieties as La France, Homère, and Marie Van Houtte.

Hydrangea paniculata, Acer Negundo, the various exquisite forms of the stately Spiræa, with their graceful creamy or snow-white plumes, and many plants of kindred character, invaluable for their autumnal beauty and impressiveness, abound. Begonias and dark-hued Zonal Pelargoniums, whose decorative capabilities can hardly be over-estimated, are extensively cultivated, with splendid floral and artistic effect.

The private flower-garden, adjoining the great mansion house, though not of large dimensions, was extremely attractive; it was a radiant, varied picture, in a frame of richest green, at the time of my visit. David R. Williamson, *Manse of Kirkmaiden, Wigtownshire*.

PROPOSED EXHIBITION OF BRITISH AND FRENCH INDUSTRIES.

We have received the following letter for publication:—

British Embassy, Paris,
February 4, 1907.

My Lords,—I am commanded by the King to acknowledge the receipt of your letter of the 1st inst., in which you inform His Majesty that it is intended to hold an Exhibition of British and French Industries in London next year (1908).

The King is glad to learn that the minimum* sum necessary to guarantee the expenses of the exhibition has been subscribed. His Majesty knows from experience that the success of such an undertaking depends more on private enterprise than on State support, but feels sure that, since the project has been happily entertained by the French Government as well as by His Majesty's Government, the French and British people will come forward to support the exhibition, which has for its object the commercial prosperity of the two nations.

The King wishes the exhibition every success, and sincerely hopes that it may be the means of strengthening the friendship which so happily exists between the two countries.

I have the honour to be, My Lords,

Your Lordships' most obedient servant,
F. G. E. Ponsonby.

His Grace the Duke of Argyll, K.T.
The Right Hon. the Earl of Derby, K.G.

* The word "minimum" refers to the conditions of the guarantee, which was not to become effective until the sum of £200,000 had been reached.

[Photo by S. W. Fisher, Esq.]

FIG. 54.—CORDYLINE INDIVISA IN THE FOREGROUND, AND C. AUSTRALIS BEHIND.
(For text see page 122.)

year," is grand in its environment, which is unquestionably one of its finest characteristics, as it is surrounded with stately and venerable woods, and looks towards beautiful Ravensall across the silvern waters of Wigtown Bay. The Countess of Galloway is, happily, much interested in horticulture, so that her head gardener, Mr. James Day, receives from her every encouragement. Notwithstanding the fact that the Earl and Countess have been often from home for a lengthened period, their gardens, under Mr. Day's superintendence, have well sustained their appearance and reputation.

are cultivated with success. Black Hamburg is the prevailing early variety.

Apples of all the predominating kinds are everywhere grown extensively—the more ornamental species in picturesque situations. These include such recent introductions as Charles Ross, Rival, and Coronation. The finest Pears, grown in cordon form on the lofty walls, fruit very freely. Large spreading trees of Williams' Bon Chrétien, Louise Bonne of Jersey, Beurré Diel, Beurré Superfin, and Marie Louise Pears are magnificent on the walls. The variety last mentioned is especially appreciated by Mr. Day,

THE PROPAGATOR.

THE CUTTING BED.

If the garden is provided with a warm propagating house, there are many plants grown under glass which may be struck from cuttings at almost any season. Where no such structure exists, it is an easy matter to make one with stout boards. It may be of any desired length and breadth, $3\frac{1}{2}$ to 4 feet being a convenient one for the latter, although a propagating bed which can be got at on all sides may be twice as wide. This wooden case should be placed in a small glasshouse capable of being heated

and pans, tanners' bark, half-decayed leaves of trees, or fine coal ashes should be employed in which to sink the pots, &c. Part of such propagating bed should be covered with glass lights. The total depth should be about 3 feet, and the side should be provided with several small doors, or hit-and-miss shutters, so as to enable the propagator to have complete control of the heat; and a valve should be fitted to the flow pipe in the chamber for the same purpose.

Cuttings should be inserted to the depth of $\frac{1}{2}$ to 1 inch according to species, soft-wooded ones being the more shallow, that is, when no pots or pans are employed. On such a bed

The following tropical plants can be struck from cuttings in the warmer division, viz.: species of *Ixora*, *Bertolonia*, *Sonerila*, *Cissus*, *Anoetochilus*, &c.

Cuttings of Monocotyledons.—Such plants as *Bromelia* and *Dieffenbachia* and *Phrynium* can be increased easily from herbaceous branches or shoots, whereas *Bambusas*, *Palms* and *Arundo* cannot be made so to do, and have to be struck from cuttings, which may be from 1 to 5 years old. By the first method are propagated *Pothos*, *Vanilla*, *Agave*, *Caladium*, and other genera. The cuttings of this order must have all their leaves preserved, too much time being

FIG. 55.—ORANGE EXCELSIOR, WHICH RECEIVED AN AWARD OF MERIT AT THE LAST MEETING OF THE ROYAL HORTICULTURAL SOCIETY AS GROWN BY MESSRS. RIVERS AND SON. (See page 109.)

up to a temperature in winter of 70° , if so high a degree be needed without unduly heating the hot-water pipes—i.e., these should be sufficient for the purpose. Two or four $4\frac{1}{2}$ -inch pipes may run beneath the bed, and two on each side of the central pathway. The case should be divided into two stages, the lower for the pipes and the upper for the cutting bed, the dividing floor being made of round staves, over which coarse sacking—coffee bags and the like—are spread. Over this floor there should be placed a 4 to 6 inch layer of soft peat and fibrous loam, and above this a layer of clean silver or washed sea sand, into which the cuttings should be inserted. If propagation is carried out in pots

soft-wooded plants such as *Alternanthera*, *Iresine*, *Coleus*, *Lantana*, *Fuchsias*, *Cuphea*, *Heliotrope*, *Verbena*, *Ageratum*, *Pelargoniums* of most sections, and most of the exotic species employed in bedding out and garden decoration may be placed. It suffices with many of these to lay them, without taking the trouble to cut each under a node or joint, on sand, earth, or leaf-mould. Air roots soon form, which seek at once to penetrate the sand, soil, &c. In close frames the action of the shut-up warmth is similar to that obtained under a great bell-glass, enough moisture being afforded to prevent wilting or withering of the leaves. The bottom heat of such a bed need not be greater than 75° to 80° .

lost before new leaves are formed. Among these plants are some with very long leaves, difficult to bring under bell-glasses, but this difficulty can be got over by binding the leaves backwards and fastening them to the cutting. Treated in this manner the leaves seldom decay. It is not necessary to take the points of the shoots as cuttings, for when divided into several pieces the operation is nearly as successful. With *Dracæna*, *Vanilla*, and *Cordylina*, the stem is cut into pieces just above a leaf and just below a bud without injuring either; similarly the stems of *Paulownia* are prepared as cuttings, the sections being 2 to 3 inches in length.

At this season Tree-Carnations may be struck

from cuttings; also double-flowered Primulas. Alpine and various hardy herbaceous plants may be struck from slips of the stems, root stock, or pieces of the root, placing these singly in small pots in a cold frame.

Cuttings of Willows of the kinds used in tying fruit trees on garden walls, and for the making of baskets; all kinds of Poplar, Golden, lacinated and common Elder, Privet of all kinds, and Sea-buckthorn may be inserted in prepared soil, and if possible in a partially shaded moist situation.

It is yet too early to graft out-of-doors subjects generally, but there are a few which may be taken in hand, viz., *Pyrus domestica* (the true Service tree), which may be grafted on thick pieces of its own roots well furnished with fibres; and the double-flowered Cherry (*Cerasus*) may be worked on the Mahaleb stock, a species easily raised from cuttings put in in the autumn. F. M.

FRUIT REGISTER.

LATE RIPENING PEARS.

BEURRE Rance ripens well here in ordinary seasons and possesses a fine flavour. It is one of the most profitable Pears, and it bears well with me on the free stock on the top of Streatham Hill. Another good late Pear is the Vicar of Winkfield. The crop of 1906 ripened well. This variety is well worth growing, for if the season is not warm enough to ripen it as a dessert Pear it is always good for stewing. The same may be said of Verulam or Spring Beurré. In some seasons this ripens well and makes a good late dessert Pear. I have known it sold (innocently) in a greengrocer's shop as Winter Nelis! These varieties require a warm season, plenty of water, and judicious storing. Grown against a wall they may suffer from drought. The free stock suits them best. W. Roupell, Harvey Lodge, Roupell Park, Streatham Hill.

LATE PEARS.

In reply to H. M., p. 37, it may be remarked that the quality of Pears often depends on soil and situation, and a variety that may be of excellent quality in one garden will not succeed in another. I have known late Pears to be ruined by drought, and others by being gathered too early. Late Pears must not, under any circumstances, be gathered till they are thoroughly mature, and when they will part readily from the spur, otherwise the fruits will shrivel at any early stage, and will never ripen, although they be kept for months. Olivier des Serres does well in most places, and this Pear keeps good until well into March. Grown on the Quince stock it does well as a pyramid tree, and also when cordon-trained. Late Pears should be stored in a very cool place, and be placed where it is warm a couple of days before they are required for dessert.

Ne Plus Meuris is a Pear worthy of extended culture; it is of medium size, and the tree is a good cropper, but the fruits require thinning, as they are produced in large clusters. This Pear succeeds best planted against a south or south-west wall, and when double-grafted on the Pear stock, the fruits are later and their flavour excellent.

Passe Crassane when well ripened is another variety of excellent flavour. It requires a long season of growth, in order to have the fruits at their best condition. It is a round Pear, with a long stalk, and is at its best from February to March.

Doyenné d'Alençon is a variety that will keep till the end of March. It can be grown as a bush or pyramid tree. This variety varies in its ripening considerably in hot and dry seasons;

it will sometimes be eatable early in January. Easter Beurré is an old favourite, needing high cultivation and plenty of moisture to bring the fruits to perfection. The fruits require much thinning to enable them to grow even to a moderate size. The best fruits are invariably obtained from single cordon-trained trees.

Beurré Rance succeeds well in a variety of positions, preferably on south-west or south-east walls. The flowers are very often ruined by spring frosts. The fruits are large and juicy and richly flavoured. It keeps in a good condition till March and April. A Pear not grown so largely as its merits deserve is Knight's Monarch. I have had fair fruits of this variety as late as May. It is very liable to drop its fruit in the final stages, and on this account some persons say it should not be thinned, but my experience teaches me the reverse of this practice, as it generally bears its fruits in clusters, and unless they are thinned early and thoroughly they will drop. This variety is liable to attacks of red spider, which must be guarded against.

Marie Benoist is a large and good late variety that keeps in fair condition until March. It bears well as a pyramid and cordon-trained tree, and the fruits need thinning. Le Lectier, a variety that is said to keep till February, was over in these gardens by the end of January.

Catillac is the best late-keeping cooking Pear. It succeeds well grown as espalier or cordon trees, and also as wall-trained trees. I have never found these fruits keep so long when grown on standard trees. Directeur Alphonse is also a good baking or cooking variety, in season from February till April. The above-named Pears are the best late-ripening sorts amongst a collection of over 70 varieties. W. A. Cook, Leonardlee Gardens.

TREES AND SHRUBS.

ILEX CORNUTA.

NOTWITHSTANDING the fact of this extremely interesting Holly having been introduced to this country upwards of half a century ago, and of its merits being pretty well advertised during the first few years after its appearance in England, it is still counted a rare plant, and the owners of good specimens are few in number. As a rule, it is of rather slow growth, increasing in width more rapidly than in height. Even when mature, it does not form a large tree, being of much smaller proportions than our common Holly. The growth is usually dense, and the same may be said of the foliage. The evergreen leaves are thick, leathery and glossy, of a yellowish green above and paler beneath. They are very peculiar in shape, being more or less oblong with two strong spines near the base and three at the apex, which give a horn-like appearance to the leaves and account for the common name of "Horned Holly." Occasionally, small intermediate spines are produced, and on mature plants the spines are often reduced in number, or entirely absent, as in *I. aquifolium*. Fruit does not seem to be borne freely on cultivated examples, but herbarium specimens represent it as red and larger than that of the common Holly. The species was first brought to notice by Mr. Robert Fortune, who discovered it in April of 1846, when collecting for the Royal Horticultural Society in China, the locality being the neighbourhood of Shanghai. About three years later it was put into commerce by Messrs. Standish and Noble, of Bagshot, and in 1850 a good figure of it was given in Vol. I. of *Paxton's Flower Garden*, p. 43, a similar illustration appearing in the *Gardeners' Chronicle* for the same year, p. 311. Eight years later, it was made the subject of a plate in the *Botanical Magazine*, t. 5039. Dr. Henry and Mr. E. H.

Wilson both collected it more recently, the neighbourhood of Ichang being specially mentioned. It thrives under similar conditions to other Hollies, but needs the sides cutting in rather more when young, to throw strength into the leading shoot. W. D.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

VARIEGATED CALADIUMS FROM SEED.—The following condensed extracts are from an article on the raising of seedlings of Caladiums from seeds, which appeared in the *Gartenwelt* for January 5:—"I possess," writes the author of the article, "a number of plants, from a sowing made on December 28, 1905, which, in August last year, had, for the most part, six to eight tolerably large, vigorous, stalked leaves. In the month of September, the Caladiums grown from corms were beginning to ripen and their leaves to droop; whereas the seedlings were then in full vigour, and their leaves showing their brightest colouring. According to my observation the seedlings grew more rapidly than the plants from corms; and they are in general less tender, and what I would lay great stress upon, they continue in growth for a longer period of time, so that by suitable cultural conditions one can have, in December and January, vigorous, well-coloured plants. Owing to this fact, those persons who are interested in these plants, and have suitable glass-houses, should adopt the practice of raising the seedlings. The corms the first year have a diameter of 2½ to 3½ cm. As is especially important with all Aroids, the seed should be sown as soon as possible after maturing, the vegetation then will range between 80 to 90 per cent. If the seed has been obtained from a varied collection, the seedlings will exhibit in the first year great diversity of leaf-colouring, and occasionally new and singular markings. Seeds should be sown thinly on a mixture consisting of: turfy loam, peat, and chopped sphagnum-moss, with a small quantity of sand added, and be so lightly covered as to be partly visible. To cover the seed is, really, not necessary, but to do so ensures more rapid and regular vegetation. A good start in a warm house should always be insisted upon. The young plants should be pricked out as soon as they can be handled, and in light, porous soil, like that in which the sowing was made. After-culture is the same as that afforded plants grown from corms." F. M.

MICE EATING THE BARK OF VINES.—(see p. 79). I have no doubt the offenders are wood-mice. They might be trapped with Nuts, Chestnuts, &c. The usual paint for vine stems—sulphur, soft soap (clay), &c.—ought to be sufficient protection. Where bitten, the vines might be wrapped with strips of old woollen material dipped in puddle made from yellow loam into which they will root if kept moist. This would assist the vines to form new bark where badly bitten. The small-meshed wire netting recommended on p. 79, might be used over all. W. Roupell, Harvey Lodge, Streatham Hill.

HOUSE FOR CARNATION GROWING.—In reply to *Enchantress*, who solicits information as to the best kind of house for Carnation growing, I would point out that the kind of structure is a minor item, and of far greater importance is a knowledge of those day by day details of culture without which but a small measure of success can be achieved. Probably some of the best "Malmaisons" ever grown in the west of England some years ago were housed in a very old-fashioned, lean-to structure which, with its small squares of glass, heavy rafters and sash bars, and not a little drip, would to-day be considered quite unsuited to the requirements of these popular flowers. One is almost inclined to say that the present-day structures in which these plants are cultivated are too lofty, too airy, and too dry. The last-named defect is possible, particularly when the dryness is the outcome of much artificial heat. The other two conditions are not easily overdone and a well-ventilated house is more or less essential. A convenient width for a Carnation house is 18 feet or thereabouts, and this will allow of two side beds, each 3 feet in width, two pathways 30 inches wide, and a 6 feet wide central bed. *Enchantress* obviously requires an inexpensive house, and one of the cheaper types is that with side walls 8 feet high with side ventilating boxes

fixed therein. The ridge of such a house would be high enough at 8 feet and the side beds would be about 6 inches above the outside level, but this is readily modified by building an additional 6 inches on the outside walls. The beds upon which the plants are stood should be covered with a solid layer of clinker and ashes. Inch iron barrel uprights should be provided to support the roof at left and right of the centre bed and 1½ iron barrel upright set in concrete to carry the ridge. The rafters should be of best yellow deal, 1½ by 8 inches gauge, and placed so as to receive a stock size of 21-ounce glass. A continuous ventilator, of a depth between 20 and 24 inches, should be affixed to the south side of the roof. Four rows of 4-inch piping should be provided in the "Malmanson" end of house, and six rows in the other section. A house such as I have described can be erected and be provided with hot-water system for about 45s. per foot run. *E. H. Jenkins, Hampton Hill.*

ARAUCARIA IMBRICATA.—We have a fine specimen of this Conifer in these gardens with two erect branches growing from the base of the trunk in precisely the same manner as the one illustrated on page 100 in last week's issue. The two branches are about 8 feet in height. We have several very large specimens of the Chili Pine at Huntsham Court. The subsoil is clay. *W. H. Collett, Huntsham Court Gardens, Bampton, N. Devon.*

A SIMPLE THREADER.—On page 76 mention is made of a new tool for fixing cotton or thread on Gooseberry bushes. I have pleasure in sending you herewith a threader which explains itself. The idea is Mrs. Fred. D. Stewart Sandeman's. *Fred. D. Stewart Sandeman.* [Our correspondent sends a very simple, but effectual, appliance. It is a piece of thin bamboo about 2 feet in length, and at one end a reel of cotton is fixed to the rod by a brass-headed nail. A notch is made in the rod near the reel and the cotton runs through the bamboo and out at the end.—*Ed.*]

A RHUBARB SHOW IN 1858.—Enclosed are particulars of a Rhubarb show held in Sheffield in 1858. They were furnished to me by the son of one of the exhibitors, and I thought they would be of interest to record. "The Rhubarb growers of Sheffield held their annual show on June 21, 1858, when the prizes were awarded as follows—Two sticks of Rhubarb: 1st prize, Mr. John Nutt, weight 19 lb. 11 oz.; 2nd prize, Mr. Padley, weight 16 lb.; 3rd prize, Mr. H. Housley, weight 13 lb. 13 oz.; 4th prize, Mr. T. Walker, weight 19 lb. 5 oz. A second exhibition took place on June 28, when Mr. John Nutt again secured the 1st prize with two sticks of Rhubarb that weighed 17 lb. 6½ oz., Mr. Padley being 2nd with 17 lb. 4 oz. The four sticks of Rhubarb exhibited by Mr. John Nutt were taken from one root and weighed 37 lb. 1½ oz." *Hy. Kershaw, Firth Lodge Gardens, Sheffield.*

BLUE HYDRANGEAS.—In favourable seasons, Hydrangeas form quite a feature in these gardens, producing an abundance of huge flower heads with the various shades of pink and blue beautifully developed. The bushes are very old and grow in a soil that is more or less impoverished by the roots of larger shrubs and trees. They are partially shaded, and as a rule get only the morning sun. The soil is light, black and shallow, overlying in some places a sandy, and in others a red gravelly bottom. The situation is sheltered and close to the sea and the climate is mild. May it not be possible that failure in the development of the much-desired blue colour is sometimes due to an over-rich soil? Your correspondent (p. 68) by the two examples he cites helps, I fancy, to support this view. *M. (near Greenock, N.B.).*

Last season, while staying in the Isle of Man, I saw many Hydrangeas, which succeed excellently in the island, but I never came across a single plant with blue flowers; they were all pink. One bush in particular, with a very large number of flowers, planted in the front of an hotel facing the sea, attracted my attention. This plant was growing in the shade, and was subjected to plenty of sea breezes, and a little salt spray occasionally. Another bush I noticed was exposed to the full sun, and this also had pink flowers. It may be said that the average outside temperature of the Isle of Man does not register as high as with me, and this fact may have a little to do with the colouring, but the principal factors are the situation and the nature of the soil. *J. C. W.*

SOCIETIES.

ROYAL HORTICULTURAL

Scientific Committee.

FEBRUARY 12.—*Present:* Dr. M. T. Masters, F.R.S. (in the chair); Dr. A. Henry, Messrs. G. Massee, A. Worsley, W. Cuthbertson, G. Gordon, A. E. Bowles, G. S. Saunders, H. T. Güssow, C. H. Hooper, C. T. Drury, J. T. Bennett-Pöe, J. Douglas, and F. J. Chittenden (hon. sec.). *Visitors:* T. S. Sim, Esq., of Natal, and J. Burt-Davy, Esq., of the Department of Agriculture, Transvaal.

Caterpillars on Gooseberries.—Mr. G. S. SAUNDERS reported that he had examined the soil from under Gooseberry bushes sent to the last meeting and had found no cocoons of the Gooseberry sawfly; he therefore concluded that the caterpillars which had attacked the bushes were those of the "maggie moth," which do not pupate in the ground, "but in leaves which it attaches to the stem by threads, or in a light cocoon fastened to the stem under dead leaves, rubbish, &c., on the ground or on walls, &c. These should be searched for and destroyed. Any leaves which hang on the bushes after the others have fallen should be collected and burnt, and the dead leaves, rubbish, &c., under the bushes should be treated in the same manner; taking up the earth under the trees will be of no avail if the sample submitted was an average one."

Apple twigs diseased.—Mr. MASSEE reported that the Apple-twigs from Falmouth showed the presence of canker, *Nectria ditissima*. He recommended that similar appearances on other twigs should be removed and "green fly," &c., should be kept down, as they distribute the fungus and also cause wounds through which it gains an entrance. Referring to other twigs shown at the last meeting attacked by *Sphaerotheca mali*, he said "diseased shoots should be cut off, as the mycelium hibernates in the bark and appears year after year. Good drainage checks the development of the parasite."

Apples spotted.—Mr. MASSEE also reported that the pitting and internal discoloration of the Apples shown at the last meeting by Mr. Hooper were due to the exceptional heat of last season, and were not in any way influenced by fungi or insects.

Cypripedium malformed.—Referring to the *Cypripedium* shown at the last meeting, Mr. WORSDELL wrote: "It is a case of fasciation, two flowers being concerned in the make-up of the whole. Taking the large flower first, the whole has become twisted out of the ordinary position, due to the untwisting of the ovary. The sepals are normal, but the lower, by the notch at its apex, shows signs of its true compound nature. Only one of the petals, viz., one of the lateral ones, is normal; both the others are curiously constituted, each being half labelliform and half sepaloid. As regards the column: the usual staminode (of the outer whorl of the andræcium) is present; there is a petaloid outgrowth which I interpret as belonging also to the outer whorl, while the two (usually fertile) stamens of the inner whorl are represented by a normal fertile and a more or less petaloid stamen. The ovary is straight, and consists of two carpels. The second flower has its stalk intimately fused with the ovary of the first; its bract is carried up so as to occur immediately below the first flower, as if forming one of the floral leaves of the latter; it subtends the bi-carpellary ovary of the second flower, which is as yet unexpanded, but the remaining parts of which were seen on dissection to be normal. A considerable number of *Cypripedium* and other Orchid sports are due to fasciation, in which two or more flowers are concerned; as, for example, in the last case reported on at the Scientific Committee by Dr. MASTERS. If this were more often borne in mind much of the difficulty of unravelling these complex structures would be avoided. The two flowers are often much more intimately blended than in the case described above."

Fasciated Bramble.—A curiously fasciated and contorted shoot of Bramble was received from Mrs. M. S. NICOL, of King's Langley.

Amaryllis spike withering.—A spike of *Amaryllis* was received from Twyford in a withered condition. It had been growing well, but suddenly stopped, and the leaves and stems became

weak and flabby. The roots appeared healthy and the bulb firm. The plant had been started about three weeks, and was plunged in a bottom heat of about 60deg. to 65deg. It was thought that the trouble was probably due to encouraging too great an amount of aerial growth before the roots were sufficiently developed to provide a proper supply of water.

Forest-journeys.—Dr. HENRY gave a brief outline of his recent travels in the Western States of America, Spain, Italy, Corsica, and Algeria, commenting particularly upon some of the forest trees he had met with, and speaking in appreciative terms of the Forest Service of the States, which in a few years has done a great amount of valuable work. The forests of the United States, he thought, were being rapidly exhausted, and this would greatly enhance the value of the woods of Canada. Mr. WORSLEY, who had recently been travelling in Portugal, remarked upon a dwarf variety of *Quercus Suber*, which covered considerable areas near Cintra, and said similar barrenness of the soil was following the destruction of woodlands in Portugal to that Dr. HENRY had described as occurring in other parts of the world. Mr. J. Burt-Davy, the director of the Department of Agriculture of the Transvaal, spoke of the species of *Widdingtonia* growing wild in South Africa, saying there was at least one species occurring wild in the Transvaal and others were cultivated, while Mr. SIM, of Natal, remarked upon the great variability of the species of this genus, one growing in the mountains merely in the form of bushes, but when transplanted to the valleys below attaining the size of a considerable tree. There appear to be many forms of this genus which are as yet not well known.

Daffodil flowering without roots.—Mr. E. H. JENKINS sent an example of a double-flowered Daffodil which had grown well, but had produced few and badly developed roots, illustrating the well-ascertained fact that flowers are produced from properly-formed bulbs when they are supplied with sufficient water and warmth, the former being able to pass apparently through the base of the bulb.

LINNEAN SOCIETY. GENERAL MEETING.

FEBRUARY 7.—Lieut.-Colonel Prain, C.I.E., F.R.S., vice-president, in the chair.

The Rev. John Gerard, S.J., F.L.S., brought forward "Some Observations of Climbing Plants," illustrating his remarks by lantern-slides from his own photographs from living plants and herbarium material. He began by pointing out the two opposing methods of describing spiral growth or torsion as viewed from the exterior or from the interior of the spiral, the result being that the "dextrorse" of the first is the "sinistorse" of the second method. With or against the sun, which applies to the northern hemisphere, is reversed in the southern hemisphere, and for these reasons he preferred to use the terms "clockwise" and "counter-clockwise" (shortened to "counterwise"); the Honeysuckle (*Lonicera Periclymenum*) and the Hop (*Humulus Lupulus*) turning clockwise, and the *Convolvulus* (*Convolvulus arvensis*) and the Scarlet Runner Bean (*Phaseolus vulgaris*) twining counterwise. He showed the result of some experiments he had made by growing Scarlet Runner Beans in opaque cylinders, to discover if possible whether the deviation of the twist were innate, or from the direction of the light, the conclusion being drawn that the plant possessed an inclination resembling the instinct of animals, of proceeding in a given direction, and resented any attempt to force it otherwise. The author concluded with some observations on the behaviour of tendrils, as those of *Bryonia dioica*, displaying one specimen which had varied the torsion four times, and showed 10 turns in one direction against 17 in the contrary.

Dr. Otto Stapf, F.L.S., then gave an abstract of his paper on "New Plants from Malaya," giving the history of his new genus *Hallieracantha*, which receives eight species from the genus *Ptyssiglottis*, Hallier f., and 11 others are added from the Kew collections; they form a very homogeneous group, are eminently shade-loving plants, and exhibit anisophylly in a very marked degree. The headquarters of the genus are in Borneo.

The last paper was by Mr. F. Chapman, F.L.S., on the "Tertiary Foraminifera of Victoria."

NATIONAL CHRYSANTHEMUM.

FEBRUARY 11.—The newly-constituted executive committee of the above society held its first meeting on this date, Mr. Thomas Bevan presiding. The following gentlemen were appointed to the Floral Committee: Messrs. Oliver, G. Hemmings, W. J. Godfrey, A. Jefferies, D. B. Crane, Ingamells, W. Howe, and J. H. Witty. The finance committee, the schedule sub-committee, and the publication sub-committee were also nominated. It was reported that the society's outstanding claim against the Crystal Palace Co. had now been fully discharged, and that the proposed arrangements to hold the 1907 shows there would be finally carried out, without delay. The Sydenham and District Gardeners' Guild, and the Bath Gardeners' Debating Society were duly admitted in affiliation, and several new members elected.

COVENTRY CHRYSANTHEMUM.

FEBRUARY 11.—The annual meeting of the above society was held on this date, the Deputy-Mayor of the city (Alderman A. H. Drinkwater) presiding. The report showed that but for increased subscriptions the society would have incurred a loss on last year's show owing to the exceptionally bad weather. The report and balance sheet were adopted. The officers for the ensuing year were appointed: President, Mr. A. E. W. Mason, M.P.; secretary, Mr. George Griffin, Coundon, Coventry; and treasurer, Mr. W. T. Browett.

BRITISH GARDENERS' ASSOCIATION.

FEBRUARY 12.—A meeting of the Executive Council was held on the above date in the R. H. S. Hall, Westminster, Mr. W. H. Divers in the chair. Twenty-four new members were elected, making a total of 1,011. The secretary reported that the Essex Hall had been engaged for the annual meeting on May 29, and it was decided that a conference on matters affecting gardeners be held on that date. The question of establishing a monthly or quarterly journal was discussed now that the membership exceeds 1,000, and the secretary was asked to report at the next meeting on the prospect of its support. It was reported that the Richmond Branch had arranged to hold a meeting on Friday, February 22, in the Fife Hall, Kingston-on-Thames, and Mr. R. Hooper Pearson was delegated to address the meeting, with Mr. A. Dean, V.M.H., in the chair, at 8 p.m.

The secretary wishes to call the attention of members to the fact that all subscriptions for 1907 are now due. *John Weathers, Hon. Secretary.*

SHROPSHIRE HORTICULTURAL.

FEBRUARY 18.—The annual meeting of the Shropshire Horticultural Society was held in the Music Hall, Shrewsbury, on the above date. The Mayor of Shrewsbury (Mr. T. Corbett) presided. The annual report of the committee was read by Mr. H. W. Adnitt. It referred to the death of Mr. G. M. Salt, who for upwards of 25 years acted continuously as chairman of committee, until his resignation in July, 1902, through failing health. Among the special features of the last show were the magnificent collections from non-competitive exhibitors, which, in the opinion of the judges, had never been equalled. The report referred in appreciative terms to the services of the railway companies' officials in conveying so unusual a number of visitors to and from the town on the occasion of the summer show. The Board of Trade had been approached with the view of obtaining license under Section 23 of the Companies Act, 1877, under which section the society might obtain the license of the Board of Trade to be incorporated by registration with Limited Liability, but without the word "Limited" to its name, with regard to their legal rights in their land and other properties. The Board had pressed their willingness to entertain such an application if made, and had settled the memorandum and articles of association. This would confer upon the society a corporate capacity, enable them to hold land and other property and deal with it in a legal way. The committee would take this important matter into consideration at an early date, and report to a further general meeting.

A financial statement was presented by Mr. J. Ne, which showed that the summer show receipts amounted to £5,394 8s. 6d., and the

expenditure to £4,175 11s. 3d., leaving a profit of £1,218 17s. 3d. The total receipts for the year amounted to £5,658 15s. 3d., and the expenditure to £5,018 3s. 1d., leaving a net profit for the year, after the payment of donations and £500 for improvements to the Quarry, of £620 12s. 2d. The society had never lost on a summer show.

The Mayor of Shrewsbury, in moving the adoption of the report, said the appreciative references to the late Mr. Salt were well deserved. The report and accounts were adopted. Mr. Peele proposed and the Rev. Mr. Hall seconded that Colonel Hope-Edwards be president for the ensuing year, which was carried unanimously. On the proposition of the Deputy-Mayor (Mr. Jones), a vote of thanks was accorded Mr. Darby for his kindness in presenting valuable prizes.

The retiring members of the committee were all re-elected.

A vote of thanks was accorded the honorary secretaries (Messrs. Adnitt and Naunton) and Messrs. Phillips and Vine.

SCOTTISH HORTICULTURAL ASSOCIATION.

(Concluded from page 110.)

THE NECESSITY FOR UNION.

Unity is strength, and so it must be in the horticultural world as it is in all other worlds. What has made our trades unions and all such other associations strong? It has been by union, by forming one great body of men, all interested in the same objects, and all using the same means of gaining the same ends, not by forming many small and independent associations all over the country or in the same town, all trying to gain the same object, but making use of different ways to gain that end.

It is only when they stand united that they can make their presence felt. Well, gentlemen, this has led me up to the suggestion that there should be union of the horticultural associations in our towns, and to give Scotland one great centre of horticulture worthy of a nation that has long been famous for the high excellence of its gardens.

In the course of a few more years, more of us must be struck from off the roll, and I therefore think that we should make some effort to hand down to the succeeding generation some monument of our efforts—a monument that will require no epitaph inscribed upon it, the epitaph of which will be engraved on the hearts of all those who take an interest in this great art.

The first question that will be asked will be: How can this be done? Well, gentlemen, I think there is no difficulty so great that a Scotchman cannot surmount it. I would appeal to our members, in the interests of horticulture, to strive to do their utmost while they are still amongst us to form one great horticultural centre for Scotland. That centre must be in Edinburgh, and were I to begin to dream again, which I do not want to do, but to deal, not with a shadow but with reality, I could see such a horticultural sun in our town dispensing its glorious light and invigorating heat over our native land that would make all Scotland blossom as a Rose, and shine forth as an emerald in the glorious light of its central orb.

Edinburgh once had an experimental garden conducted under the auspices of a horticultural association, the past history of which is most interesting to read. It is now no longer in existence. How is this? Could it not be reinstated in a city like ours, that considers itself the centre of all light and learning? This would be work for the great central society whose picture I have been painting.

Young men gardeners in Scotland are labouring under a great disadvantage in comparison with those of other countries, and they are also labouring under a very great disadvantage when compared with what is being done to educate lady gardeners in the science and practice of horticulture. The latter have their college and their experimental garden.

They have their lectures to attend and examinations to pass. Why is it that young journeymen gardeners of the opposite sex cannot enjoy the same privilege? It is simply because they have no college and no experimental garden to attend.

THE CAREER OF A YOUNG GARDENER: THE BOTHY.

Now, a few words about young gardeners who are to be the horticulturists of the future, and whose interests we have all at heart.

When a young lad on leaving school makes up his mind to become a gardener, what happens? A nurseryman is written to, and the fact is intimated, and his assistance is requested. In course of time an application for an apprentice is made, and after a few preliminaries are arranged, the lad is despatched with the inevitable trunk, and arrives at his destination perhaps in some outlandish spot where gardening is not one of the features of the place. He is put into what is called a bothy along with one or two other men, and he is told he will not only have to cook his own food, but also that of the others. That he will have to light the fire, clean the bothy once a week, and wash up the dishes when he can find time, which in some cases may be once a week, and, in fact, he will have to do all the menial work in the bothy. He is taken out to the garden and set to work. The first job he may be given to perform will perhaps be to wheel coals, or probably ashes, or to wash pots. I should not object to the latter; I have done it myself, and it teaches one cleanliness. He may then be given a spade, but possibly no one will show him how to use it, and he may not know the back from the front, but he flounders on till he gains some idea of how to use this instrument. He will be set to clean up after all the other men in the garden, and when able he may be

allowed to take his share in all the other work. How does he spend his evenings? Well, he has not much time to spare, as the bothy takes up a good deal of his time in the evenings trying to make it look respectable. He has no gardening papers and no books to read, and has no one to take any interest in his future career. He joins the other men in going to the nearest village or round the draught-board, with a light almost too dim to see the white from the black diamonds, and this goes on for three years, at the end of which time he is told his time is up, and he must make a change. He is again sent to the inevitable nurseryman with a note in his hand, announcing the fact that he has completed his three years' apprenticeship and wants a journeyman's situation. He comes in like a lost sheep, nervous, cold, and it may be hungry, and not as much money in his pocket as will pay his expenses to his next situation. He is despatched to some place perhaps more distant than where he came from, and when he arrives at his new situation he finds it not so good as the one he left, but he gets a few more shillings per week, and has an apprentice to cook his food and wash up after him. He remains here for a time, then seeks another change, and so on it goes till he is appointed to some small situation at 21s. per week with etceteras, never having thoroughly learned his profession. During the time of his wandering up and down he has hardly ever seen a gardening book or a gardening paper, and knows nothing about what is going on outside his own domain.

Now, gentlemen, I would ask you if a young man living in such surroundings as this is ever likely to become a great man. True, many have done so, I admit. To my mind I can think of nothing more likely to crush ambition out of the heart of a young man or sicken him more against his employment than the surroundings of an apprentice, and, in many cases, of a journeyman gardener.

Some of you older men may say: "I have passed through all those stages and under similar circumstances, and I don't see why young men of the present day cannot do the same. But that is not progress. Scotland a few hundred years ago was inhabited by a race of people who were very little above the savage races, and so was our now great ally, Japan, and unless both had developed, they might still have been in that same savage state. How are we to improve the position of the rising generation of young gardeners? Supposing we had an experimental garden, a good-sized one, and in that garden we had what we will call a college, a residential college, not a bothy, and supposing in that college there was accommodation for from 30 to 50, or from 40 to 50 young men who would have some one to cook their meals for them, wash up after them, and keep their rooms tidy and in good order. Supposing there was a reading room where no smoking was allowed, and another where smoking was allowed, and where all the gardening papers of the day were to be found, where there was a select library of books, comfortable rooms where men could read and study, where lectures could be given, and where young men would have to pass examinations. In this garden there would be fruit-houses and plant-houses, forcing-houses, and orchard-houses, and fruit growing and vegetable growing would all be carried out in an up-to-date fashion; where all new things as well as old would be sent for trial, and where the young men would be brought into contact with everything in the way of useful gardening, and where they would be taught the art in all its fullest details by practical men; where they would be taught not only the practice but the science of gardening. Such an institution as this, if once started, could be almost self-supporting. Here is a school from which to draw an up-to-date gardener, either journeyman, foreman, or master.

THE BRITISH GARDENERS' ASSOCIATION.

There has been an association formed in the South called the British Gardeners' Association, one of whose aims is to raise the social position of the gardener by attempting to raise their remuneration, by not sending men to situations unless they are to receive a living wage. If the gardener's social position is to be raised it must be done by educating them in such a way as I suggest, and all other good things will naturally follow. The Gardeners' Association has, I fear, begun at the wrong end.

Obituary.

J. S. UPEX.—We regret to record the death of this well-known gardener, after a long and painful illness, at Wigganthurpe Gardens, of which place he had the care for 16 years as Gardener to the Hon. H. N. Fitzwilliam. Deceased was a contributor to our pages, and for several years has contributed to our yearly report of the fruit crops.

ENQUIRIES AND REPLIES.

AN EXHIBITION QUERY.—At a provincial summer show last year I was acting as one of the judges when the following class came under our adjudication. The decision given has caused much dissatisfaction to the exhibitor, so much so that he brought it forward at the annual meeting, but with no satisfaction to himself. The class reads thus: "Three vases of Carnations, distinct, each to contain four blooms; to be shown as grown and with Carnation foliage only." We inferred from the wording of the class the donor intended to encourage varieties

suitable for the open, requiring no support, showing their value as varieties in a natural manner. The first prize exhibit was found afterwards to have the blooms supported by small wires. This, we contended, was an infringement of the wording "as grown." If a variety requires supporting, it cannot be so valuable as one self-supporting by its stems. The aggrieved exhibitor wrote to an official of the National Carnation Society, who said the judges were distinctly wrong in disqualifying the exhibit. I wonder what is the consensus of opinion on a somewhat knotty point by the readers of the *Gardeners' Chronicle*. *E. Molyneux*. [The fault lies not with the judges or exhibitor, but with the compilers of the schedule [or donor]. It is indefinite, and everyone is left to guess for himself what the committee [or donor] had in their mind when they wrote the words "as grown." As written, it is the "vases" that are to be distinct. To show the futility of such terms, one might ask how the flowers, not the vases, are to be shown "as grown" when they surely grew upon plants, yet have to be exhibited as cut flowers. It would be fair to conclude that "dressing" was purposely excluded by the words—indeed, they might be read in all sorts of ways. On the whole, we think the judges were right.—ED.]

CEDRUS DEODARA.—I have found that this Cedar thrives in the suburbs of London for about 40 years and then often begins to die at the top. Generally planted in the centre of the lawn in front of the house, the building shelters it for a time, and so soon as it rises to the level of the house it begins to fail, principally, I think, from cutting winds. The soil also in such situations is not often adapted to promote longevity. The same remarks apply also to the Puzzle-Monkey (*Araucaria*). We do not suffer much from smoke on Streatham Hill. *W. Roupell, Harvey Lodge, Roupell Park, Streatham Hill, S.W.*

PRIMULAS.—Will some reader inform me if they have succeeded well with the giant strain of *Primula sinensis* and the stellata strain, as two-year-old plants? What treatment was afforded? *S. G.*

ANSWERS TO CORRESPONDENTS.

ANNUALS FOR CUTTING: *J. D.* The following annuals are suitable for furnishing a supply of cut flowers: *Callistephus chinensis* (Chinese Aster), *Centaurea cyanus*, *C. moschata*, *Atriplex hortensis*, Marigolds, *Gypsophila elegans*, *Helianthus* species, *Coreopsis*, *Cosmos bipinnata*, *Brachycome iberidifolia*, *Saponaria calabrica*, Sweet Peas, *Chrysanthemum carinatum*, and *C. coronarium*, *Helichrysum bracteatum*, *Mignonette*, *Dianthus sinensis*, Larkspurs, *Matthiola bicornis*, Poppies, *Silene pendula*, Zinnias, *Iberis umbellata*, *Leptosyne maritima*, Stocks, Scabiosa, *Clarkia*, &c.

BEANS: *C. W. T.* These are probably of a species of *Phaseolus*, and agree very nearly with *P. vulgaris*, the seeds of which vary considerably in size, colour and form.

BOOKS: *W. P.* We are not secondhand book-sellers and cannot tell you what price a single volume of Smith's *Flora Britannica* would fetch. We know of a book with such a title in 8 vols., but we do not think it can be the same as you describe as having 183 coloured illustrations of trees and shrubs and cultural directions, plates engraved by Sanson from drawings by Sydenham Edwards.—*W. R. H.* asks the probable price that would be obtained for a fine copy of Parkinson's *Paradisus*, Dodoens' *History of Plants*, and *Hales Eden*, all perfect. We are not able to give the information required, but we shall be pleased to put any book-lover in communication with our correspondents. In any case an advertisement would probably bring a reply.

CARNATIONS: *H. B.* Your plant is affected with the maggot of the Carnation fly, *Hylemia nigrescens*. Try washing the "grass" with quassia water.

DIGGING: *F. V.* We do not think your remarks are called for. Supervision of work is always desirable, and it is as necessary in respect to digging as other garden operations.

EVERGREEN SHRUBS: *E. H. F.* The appearances are those which would be caused by frost, and by the sun shining on the frozen leaves.

FOUND IN POST WITHOUT CONTENTS. Such is the endorsement made by the Post Office authorities on a luggage label addressed to us from Salisbury. Perhaps the sender will kindly note that his consignment has been lost.

FLOWERING GOOSEBERRY: *R. W. P. S.* From your description we expect that the plant is *Ribes aureum*.

IRON SULPHATE FOR VINES: *Cray.* A formula for iron sulphate solution is as follows: water 50 gallons, sulphuric acid 1 pint, and iron sulphate 25 pounds. Pour the acid on the iron sulphate, and when this latter is dissolved, add the quantity of water mentioned. This preparation is only suitable for applying in winter to the leafless shoots, and limbs of fruit trees. It must be handled with the greatest care, and must not be used as a spray on any account if the vine buds are beginning to break into growth.

MALT COOMBS: *J. Taylor.* This material is more suitable for cattle feeding than for manure, although it is occasionally used as such. Its manurial value may be stated thus: Humus-giving material, 90 per cent.; nitrogen, 4 per cent.; potash, 4 per cent.; phosphoric acid, 2 per cent. It is seen that the principal part of the substance is organic matter from which, when added to the soil, humus is formed. It is not a lasting manure, the nitrogen is very soon used up; it has, therefore, to be supplemented by some other material, such as stable manure or a commercial fertilizer. For Lawns a dressing of 5 cwt. basic slag or superphosphate per acre should be given in winter or early spring, to be followed in March with an application of 10 cwt. per acre of malt coombs if the soil is poor and mossy; if it is rich in fertility, 5 cwt. malt coombs will be sufficient. For Vegetables the ordinary manures in general use may be supplemented by a dressing of 1 ton of malt coombs per acre, to be lightly dug or raked in previous to sowing seed or putting out plants. Malt coombs may be advantageously sprinkled between rows of Strawberry plants as soon as they begin to bloom. If malt coombs are dug or ploughed deeply into the soil, very little beneficial effect will be observed from their application. They are more suitable for light and loamy soils than for heavy, stiff clays.

MARGUERITE: *E. J. M.* The leaves are disfigured with the caterpillars of the well-known leaf miner. You will be able to find some still in the leaves, between the skins. Each one causes a sort of excrescence. Pinch them between the thumb and fingers. If you syringe the plants with quassia extract occasionally, it will render them distasteful to the perfect insect, and so prevent them from laying their eggs on the leaves. (See illustration in *Calendar of Garden Operations*, obtainable from our publishing department, price 7d., post free.)

NAMES OF FLOWERS, FRUITS AND PLANTS.—We are anxious to oblige correspondents as far as we consistently can, but they must bear in mind that it is no part of our duty to our subscribers to name either flowers or fruits. Such work entails considerable outlay, both of time and money, and cannot be allowed to disorganise the preparations for the weekly issue, or to encroach upon time required for the conduct of the paper. Correspondents should never send more than six plants or fruits at one time: they should be very careful to pack and label them properly, to give every information as to the county the fruits are grown in, and to send ripe, or nearly ripe, specimens which show the character of the variety. By neglecting these precautions correspondents add greatly to our labour, and run the risk of delay and incorrect determinations. *Correspondents not answered in one issue are requested to be so good as to consult the following numbers.* **FRUITS:** *J. J. G.* 1, Radford Beauty; 2, decayed; 3, Alfriston.—*D. R.* Blenheim Pippin.—*D. K. S.* 1, Harvey's Reinette; 2, New Bess Pool; 3, Ribston Pearmain; 4, White Paradise.

PLANTS: *H. C.* *Ornithogalum lacteum*.—*M. A. T.* A very good variety of *Cypripedium Boxallii*.—*R. R.* *Oncidium pulvinatum*.—*T. H.* 1, *Oncidium incurvum*; 2, *Brassia verrucosa*; 3, *Bulbophyllum suaviissimum*; 4, *Sophranitis cernua*; 5, *Lycaste aromatica*; 6, *Odontoglossum blandum*.—*R. B. B.* 1, *Pteris longifolia*; 2, *Adiantum colpodese*; 3, *Blechnum occidentale*; 4, *Selaginella laevigata*.—*P. Q.* 1, *Pteris argyrea*, the one with white middle; 2, *Polypodium vulgare semilacerum*, syn. *hibernicum*; 3 and 5, *Cattleya Trianae*; 4, *Dendrobium*

Wardianum.—*C. Ramsgate.* *Helxine Soleirolia*, used in gardens for the same purposes as the dwarf Mosses.—*J. W. O.* *Chimonanthus fragrans*.

PEACH SHOOTS: *F. S. H.* The death of the buds is due to some error of detail in management, but we cannot say what.

PEACH TREE DEAD: *S. C.* The roots show no trace of fungus disease, but the tree may have been badly affected with "silver leaf." When planting another tree do not neglect to thoroughly sterilise the walls and the soil against fungus spores by syringing with a strong fungicide, using carbolic acid on the walls, and Jeyes' fluid to the soil.

PELARGONIUM HENRY JACOBY: *Geranium.* It may be that the plants are not of this variety at all, and as change of stock is sometimes desirable, you should secure cuttings next season from some other source. You must, however, remember that flowers produced during the winter cannot be expected to have their colours developed so well as in the summer time.

ROSES FOR MARKET SUPPLY: *J. R., Midlothian.* Having regard to the conditions in your district the following varieties of "Hybrid Perpetual" Roses are recommended as being the hardiest for outdoor culture: *Crimson*, General Jacqueminot, Charles Lefebvre, Captain Hayward, and Hugh Dickson; *pink*, Mrs. J. Laing, Mrs. R. G. Sharman-Crawford, Mad. Gabriel Luizet, and Baroness Rothschild; *white*, Frau Karl Druschki, Boule de Neige, and Margaret Dickson. For yellow flowers you must fall back on the "Teas" and "Noisettes," such as *Etoile de Lyon* and *Souvenir de Pierre Notting*.

SULPHATE OF COPPER: *E. P.* Copper sulphate enters into the composition of the Bordeaux mixture, and we should prefer to spray the Carnation plants with this latter preparation. Taking the formula for Bordeaux mixture as water 50 gallons, copper sulphate 6 pounds, and unslacked lime 4 pounds, you might use this at about half strength.

SULPHUR: *N. C. C.* Sulphur is useful to destroy mildews and other surface fungus diseases, and it is applied by dusting the powder of flowers of sulphur directly on to the foliage or by painting the water pipes with a mixture of sulphur and water, or by syringing water containing sulphur over the plants in the form of a spray. You do not name any specific disease, but we may say that the Bordeaux mixture is an excellent fungicide, and others include a solution of sulphate of copper, potassium sulphide (liver of sulphur), ammoniacal solution of copper carbonate, &c. These fungicides, however, need to be used with great care, and if you have had no experience with them you would do well to read the *Text Book of Plant-Diseases* by Geo. Massee, and obtainable from our publishing department; price 5s. 4d., post free.

VINES: *J. P.* We should think the death of the roots is due to the condition of the border. Make a new, well-drained border, and start afresh.—*E. A.* The shoots should be stopped just beyond the second leaf after the inflorescence (flower bunch).

VIOLET FRAME: *J. R. F.* Get fresh soil if you can, but, failing this, it is not likely that the Violet disease will attack the Stocks, Asters, Zinnias, &c.

WOODLAND FOR PERMANENT PASTURE: *Tulaculum.* If the clay is not excessively stiff, but sandy and loamy as you describe it to be, it would be well to break this up by trenching, and to mix some of it with the few inches deep of leafmould now at the surface. A crop of Potatoes taken this year, as you suggest, would be a very good means of cleaning the soil. You should procure a book on the subject of permanent pastures, such as that by Mr. Martin J. Sutton, Reading.

WREATH MAKING: *Student.* Busy firms would have no time to spare in giving you tuition in this art, unless you were willing to go as an apprentice. You should advertise for someone connected with a good firm willing to impart the knowledge for a remuneration.

THE STERILISATION OF SOIL.

CULTURAL sterilisation means the destruction of all ordinary animal and vegetable life contained in the soil, by means of steaming, baking, or other methods without prejudice to its fertility. This is of the highest interest and importance, for, as shown by the Rothamsted investigators as the result of elaborate and prolonged researches: (1) Most of the nitrogen assimilated by crops—plants, flowers, fruits, and vegetables—is derived from the nitric acid contained in the nitrates in the soil; (2) the nitric acid in the soil is produced from the nitrogenous compounds of the soil itself, from the nitrogenous organic matter of animal and vegetable remains and manures, from the ammonia of artificial manures, and from the ammonia supplied by rain and condensation from the atmosphere. A very small quantity of ready-formed nitric acid is supplied by rain and condensation direct from the atmosphere. Nitric acid in combination is also provided by the direct application of nitrates. (3) The ammonia of ammonium-salts is rapidly converted into nitric acid in the soil, as also is the nitrogen of some organic matters, such as urine. The nitrogen of rape-cake, that of the less soluble parts of farmyard manure, of stubble, or

roots, &c., is much more gradually converted into nitric acid, and it may require many years for the conversion of the whole of it. The nitrogenous compounds of the soil itself are very slowly converted into nitric acid, but the soil yields a certain quantity every year.

The conclusions to be drawn from the foregoing data are: (a) That where the soil is of a turfy nature, as in the case of loam cut from a pasture to a depth of 2 or 3 inches, or the surface soil of land that has been liberally dressed with animal manures taken as compost, there will be an accumulation of nitrogenous and mineral matter, and such accumulation constitutes what is known under the term "condition." (b) In order to conserve this "condition" the soil must not be sterilised, that is, its contained organic substances must be retained, for upon the presence of nitrates and the ammonia yielding matter depends the present and continued fertility. In brief, the fertile soil must not be sterilised by heat to the extent of annihilating the organic matter, or even to the degree impairing its fertility.

The reasons for not so sterilising the soil are twofold: (1) In order not to destroy the contained organic substances which, in decay, are converted into carbonic acid, water and ammonia. (2) To retain unimpaired the bacteria that effect nitrification, both the micro-organisms that possess the property of converting ammonia into nitrous acid, and the other micro-organisms that possess the power of converting nitrous acid into nitric acid, which combines readily with the lime, potash, or soda present in the soil to form a nitrate of these elements, and these nitrates, by their solubility, are soon dissolved by water, and are very readily taken up by growing plants.

CULTURAL STERILISATION.

Thus the term "sterilisation" is a misnomer, for the soil, steamed, or baked, or otherwise treated for the destruction of contained parasitic animal and vegetable pests, is not, when properly treated, sterilised, or, in other words, is not deprived of its "condition" and of its sources of sustained fertility. Indeed, cultural sterilisation, a very different thing from scientific sterilisation for experimental purposes, has the effect of rendering the nitrogenous matter more readily available for nitrification, and also of rendering some of the soil constituents more soluble, while at the same time it destroys the herbage—weeds and weed seeds, insect and fungoid pests, Lichens, Liverworts, &c. Soil under glass becomes sour and stagnant in the course of time, impeding the work of beneficial micro-organisms; hence the need of frequent renewal or renovation. Plant-foods are obtained partly from the air, and of these carbonic dioxide and water are the chief, and partly from the soil, and these latter supply the nitrogen compounds, as well as potassium, phosphorus, and other elements. These elements are worked up by the plant, by the agency of light on the leaves, into complex compounds, such as sugar, starches, fats, and proteids. When vegetation is used as food by animals, part of the nitrogenous elements is utilised for the formation of new albuminoid substances in the animal body, but a part of them is at once reduced into the somewhat simpler condition known as urea, the form in which

waste nitrogen is commonly excreted from the animal body. Urea, however, is not a plant-food, for ordinary plants are entirely unable to use it. Part of the nitrogen absorbed by the animal is stored up in the animal's body, and thus it contains, after it has died, nitrogen and other compounds of high complexity, which plants are not able to use: that is, a plant cannot be fed upon fats, muscle-tissue, and bones, they being of no use, in those conditions, to the plant, as they must be first broken down into less complex substances by the aid of bacteria. The whole process is one of decay, resulting in the decomposition of the tree or animal. What has become of the matter? Part of it has passed into the air in the form of gases and water-vapour, and part of it has changed its composition and has become incorporated with the soil.

DECAY AND PLANT FOOD.

This process of decay of organic matter is one in which bacteria play the most important part. In the decomposition of animal tissues bacteria mainly, if not alone, are the agents, and they are always present in the air, in the soil, and in the water, ready to seize upon any organic substance that provides them with food. This chemical decomposition breaks up the complex bodies into simpler compounds, and the final result is a thorough destruction of the plant or the animal or the material excreted by animal life, and the reduction of all into forms simple enough for plants to use again as foods.

But in the decomposition that thus occurs some of the material is changed into compounds too simple for use as plant-food, and among these are those containing the nitrogen. The changes result in the formation of nitrogenous products as simple as ammonia, or into compounds which the chemists speak of as nitrites. These compounds are not ordinarily within reach of plant life, for plants chiefly extract their nitrogen in the form of nitrates from the soil. Nitrates contain considerable oxygen; ammonia, one of the products of putrefactive decomposition, contains no oxygen; and nitrites, another factor, contain less oxygen than nitrates. These bodies—ammonia and nitrites—are too simple for plants to make use of in their uncombined condition.

NITRIFYING BACTERIA.

Now come in the micro-organisms known as nitrifying bacteria, which exist in the soil everywhere. These organisms grow and feed upon the soil ingredients, and in the course of their life bring about a union of the nitrogen with oxygen. There are several different kinds of nitrifying bacteria with different powers. Some of them cause an oxidation of the nitrogen products by means of which the ammonia is united with oxygen and built up into a series of products, finally resulting in nitrates. By the action of other species, still higher nitrogen compounds, including the nitrites, are further oxidised and built up into the form of nitrates. After the nitrifying organisms have done their work, the nitrates are left in the soil, and these may enter into the roots of plants as foods.

Even yet the food cycle is not complete, for some of the nitrogen of the dead and decomposing plant or animal passes into the air in

the form of ammonia, and this evolution goes on wherever that putrefaction takes place. This part of the nitrogen has passed beyond the reach of the plants, and there are still other methods by which nitrogen is lost to the soil. There is loss by the gradual washing away by the draining into the ocean—a slow but sure extraction of nitrogen from the soil. Much loss also goes on through the disposal of sewage by the large towns away into the sea.

Much nitrogen is also wasted in the manufacture of explosives. Saltpetre, for instance, is equally good as a fertiliser and as a basis for gunpowder. Indeed, man throws the most valuable of plant foods away, and it is this taking from the stores of nitrogen that in a large measure forces farmers and gardeners to purchase fertilisers.

Bacteria, however, have the power of reclaiming from the atmosphere more or less of this dissipated nitrogen. The bacterial life acts in at least two different ways. In the first place it has been found that soil entirely free from all common plants, but containing certain kinds of bacteria, if allowed to stand in contact with the air, will slowly but surely gain in the amount of nitrogen-compounds it contains, and that these nitrogen compounds are manufactured by the bacteria in the soil is plainly shown by the fact that they do not accumulate unless bacteria in the right quantity and of the proper species are present. This fixation of nitrogen is not performed, as a rule, by any one species of micro-organism, but by two or three of them acting together, for when certain combinations of bacteria have been placed in the soil, this fixation of nitrogen resulted, but no one of the species was found capable of producing this result alone. How far this fixation of the free nitrogen from the atmosphere extends has not been determined. G. Abbey

(To be continued.)

RARE TREES AT COLDRENICK.

FOLLOWING the lead of Sir Charles Lemon in the west and of Sir William Molesworth at Pencarrow in the east of Cornwall, Mr. E. J. Trelawny, better known by his famous cognomen "Greek" Trelawny, planted at Coldrenick many rare coniferous and other trees and shrubs. "Greek" Trelawny was an intimate friend of Shelley and Byron. In 1822 he recovered Shelley's body and was present when it was burned on the sea-shore at Via Reggio. Later in life he sat as the mariner for Millais' famous picture, "The North-West Passage." Mr. Trelawny was a descendant of the famous Bishop of Bristol, one of the seven bishops tried on June 29, 1688. Their trial and prompt acquittal is a matter of history. Bishop Trelawny was a Cornishman, and his danger roused his countrymen to an intense pitch and inspired the writing of "Trelawny," the rousing war-song and march-past air of the Cornish Regiment. The refrain of it runs:—

"And shall Trelawny die?
By Tre, Pol, and Pen,
Twenty thousand Cornishmen
Shall know the reason why."

Coldrenick lies four miles south of Liskeard, and is surrounded by most romantic scenery. To the west is a remarkable succession of steep hills and deep valleys, several of which are bridged by the railway. One viaduct—over 100 feet high—is built across the lower portion of the Coldrenick estate. A few miles to the south the view embraces the broad Atlantic, White-sand Bay, and the beautiful Looe Harbour. Contrary to the general custom in Cornwall, the mansion is built on high ground, and while it enjoys many fine views it is exposed to the fierce gales which periodically sweep the

country. This has necessitated the planting of a broad belt of shelter trees to protect the rarer subjects. Attached to the mansion is a conservatory, and in front of this is a formal flower-garden. Our visit to Coldrenick was made principally to inspect the trees, and among the many fine examples seen prominent mention must be made of the very rare and magnificent Himalayan Larch (*Larix Griffithii*). According to Veitch's *Manual of the Conifera*, this graceful tree was first discovered in Western Bhotan by the indefatigable botanist whose name it bears. In 1848 Sir Joseph Hooker sent seeds from Sikkim to Kew, where numbers of seedlings were raised and afterwards widely distributed, but nearly all these plants died. [See

same age, is in the Pencarrow pinetum. *Larix Griffithii* develops stout, horizontally disposed branches, and from these hang long pendulous branchlets which, when furnished with leaves, sway in the slightest breeze. They are thickly set with unusually large brown-tipped spurs. The leaves are in denser tufts and are broader and stouter than those of the common Larch, and in autumn change from a healthy green to a dull brown colour and remain on the trees till late in the year.

The young cones which usually appear at the middle of March are larger than those of *L. europæa*. At first they are yellow tinted with green, but the green colour soon fades, and after pollination the yellow gives place to

FIG. 56.—*LARIX GRIFFITHII* AT COLDRENICK.

Sir Joseph Hooker's drawing and account of this tree in our issue for June 5, 1886.—[ED.] I know of only three trees of any size, and of these the specimen at Coldrenick is the finest. It is 57 feet in height, with a straight tapering trunk clean of branches for 20 feet from the base, and it has a girth of 4 feet 7 inches at 5 feet from the ground. From where it branches to its top the tree is remarkably well balanced, with series of horizontal branches.

At Strete Raleigh, near Exeter, there is a fine tree that measures 50 feet in height, and with a bole 5 feet 3 inches in circumference at 5 feet from the ground level. This tree has a very large branch on one side which detracts from its symmetry. A smaller tree, of probably the

brown. Even in the young stage the cones, which are freely produced, are very large for the genus; an average cone measures 3 inches in length and 3½ inches around. The cone bracts project and are reflexed. The seeds germinate freely, but the seedlings require careful handling, as they readily "damp off."

Mr. Skin, the head gardener at Coldrenick, showed me a healthy batch of two-year-old trees which he has been successful in raising. Plenty of light and air and careful watering are necessary with these, as with all other seedling Conifers. Recently while planting a young specimen of *L. Griffithii* I noticed that the root tip was of a bright pink colour.

Near by is a very shapely plant of *Torreya*

FIG. 57.—*LARIX GRIFFITHII*, THE
HIMALAYAN LARCH, GROWN IN
CORNWALL.

californica, in height about 35 feet. The Californian Nutmegs are comparatively rare in England. Growth is said to be very slow in the early stages, but where the plant thrives it ultimately makes such a handsome tree that quite recompenses this initial disappointment. *Pinus insignis (radiata)* thrives well in the moist atmosphere of Cornwall, and those at Coldrenick are no exception. The tallest example measures 85 feet, and has a girth of 14 feet at 5 feet from the ground. Near by this last mentioned tree is a shapely *Libocedrus decurrens* that is just over 50 feet in height, with a trunk 6 feet 6 inches in diameter. A tree of *Fitzroya patagonica* has branched close to the ground and grown up into a many-stemmed large bush, as is usual in our country with this South American Conifer, which at home is said to form a lofty tree. The tree under notice has six stout branches, the tallest being 24 feet high, well furnished with the characteristic pendulous branchlets. Nearly opposite this *Fitzroya* is a beautiful tree of *Dacrydium Franklinii*—by far the finest specimen I have ever seen of this rare and beautiful Tasmanian Conifer. It is over 12 feet high and has a spread of branches 24 feet in diameter. The main branches are developed nearly horizontally, and from them hang secondary branches 4 to 5 feet in length and densely clothed with healthy dark green foliage. A *Retinospora squarrosa* (Hort.), some 30 feet in height, is a very pretty and well-furnished specimen.

Several examples of *Cryptomeria japonica* form quaint and striking trees. Here they usually branch when from 5 to 10 feet high, and form five or six stems, which give the trees a very eastern appearance. At this part of the estate there is a fine avenue composed of *Sycamore* and *Beech* trees planted alternately, and at the end of this avenue is obtained a fine view of the surrounding country. The mammoth *Sequoia gigantea* (Wellingtonia) usually does only moderately well in Cornwall, so that I was not prepared to see such a fine specimen as the one at Coldrenick, which is over 75 feet in height and shapely, with a girth of 9 feet 6 inches at 5 feet. *Pinus parviflora* is not, of course, so large a tree, but there is one well grown and bearing an unusually large number of cones. By its side stands a fine tree of *Thuja dolabrata*, that is quite 35 feet high, of perfect shape and broadly pyramidal in outline.

A specimen of the rare *Evergreen Beech* (*Fagus betuloides*) arrested my attention; unfortunately it has been much overgrown by the shelter belt. The tree is of a goodly height, but it is much branched and one-sided. A 25 feet high *Cephalotaxus Fortunei*, with a goodly crop of small green, plum-like fruits, has shared the same fate, but from the path side it is a most beautiful object. Mention must also be made of a charming tree of *Saxegothea conspicua*, 30 feet in height and well furnished with healthy drooping branches. In some Cornish gardens this Chilean tree is confounded with the rather more common *Prumnopitys elegans*, which has the same habitat. When seen growing side by side there is only a slight similarity to be detected. Both trees have, especially when young, a general Yew-like appearance, but here the similarity ends, and the two trees, once properly seen, should not be difficult to distinguish.

In the background there stands a very straight *Cedrus atlantica*, that rears itself 65 feet high and with a girth of 5 feet 7 inches. The specimen is symmetrical and of very good form. A giant *Thuja* (*T. plicata*) is over 60 feet high and has a girth of 7 feet. *Cupressus obtusa aurea* measures 30 feet, and has every appearance of being still higher, for its top has not yet become rounded. This is a beautifully coloured specimen.

Besides planting these specimen trees, Mr. Trelawny made an extended planting of many

of them, to test their value for timber purposes. The trees already noted occupied nearly all the time at my disposal, so that I had perforce to content myself with just a glance at this valuable and highly interesting plantation. But I was able to see that so far as growth and straightness of bole was concerned, the Douglas Fir, *Thuja plicata* (more generally known as *T. gigantea* or Lobbi of gardens), *Abies Nordmanniana*, a Silver Fir which grows remarkably well all over Cornwall, *Pinus excelsa*, and *Cryptomeria japonica* quite held their own when in company with such trees as the Scots Pine, Larch, Oak, Beech, &c., that have been planted with them. A. C. Bartlett.

ORCHID NOTES AND GLEANINGS.

EPIDENDRUM RHIZOPHORUM.

THIS well-known species is easy of cultivation and well repays the trouble of culture, although the plant requires a considerable amount of room when in flower. I was desirous of having this plant in flower for a local show in June, and I left off tying down the leading shoots in November, 1905, and raised the plant as near to the glass as possible, but no flower scapes appeared until August of last year. As a consequence, however, we have had a charming plant with over 50 inflorescences, with from 15 to 20 bright, flame-coloured flowers on each. It opened its first flowers early in November, and is probably at its best condition now (January 17), though it will remain in flower for some time yet. The plant should be placed near to the glass, and receive a plentiful supply of moisture at all times, a free rooting medium, and an unfettered freedom of growth of the leading shoots. The plants here have been kept in a temperature of about 60°; no fire heat is provided in summer time, but plenty of sunlight and air are then admitted. The plant may be had in flower all the year round, the time of flowering depending on the time the shoots are tied down. H. W., Trevinice.

CYPRIPEDIUM MISS DORA WEBB

(Minos Young's variety x Sander's var. of nitens).

THIS latest, and one of the prettiest, of the now numerous hybrids in which *Cypripedium Fairrieanum* has played a part, is flowering in the collection of Francis Wellesley, Esq., Westfield, Woking (gr. Mr. Hopkins).

In this case the presence of *C. Fairrieanum* comes through *C. Minos Young's* variety (*Spicerianum magnificum* x *Arthurianum*), the latter being derived from *insigne* crossed with *Fairrieanum*.

C. Miss Dora Webb has fine flowers of perfect shape, good substance, and very attractive colouring. Moreover, like most of the other descendants of *C. Fairrieanum*, it flowers in winter when the blooms are most needed, and lasts an extraordinary time in good condition. The large dorsal sepal is pure white, with a small emerald-green base, a broad, dark purple band up the middle, and a very showy arrangement of small purple spotting over the central two-thirds of its area. The petals, which are broad and wavy on the upper edge, are pale greenish-yellow, tinged with purple and slightly veined with the same colour. Lip yellow, tinged with reddish-purple on the face, the infolded side lobes being chrome-yellow, and the interior densely spotted with a dark shade of rose. The whole flower has a shining surface and a very bright appearance.

The value of the *Fairrieanum* crosses as winter and spring flowers has been well demonstrated in Mr. Wellesley's collection, where, in December and January, the following plants were in flower:

PRIMARY CROSSES OF *C. FAIRRIEANUM*.—*Cypripedium Princess*, H. Ballantine, and the fine Westfield variety; *Juno superba*, Baron Schröder, Niobe and its varieties, Oakwood Seedling, luteum, Westfield, exquisitum, Westonbirt, excelsum mag-

nificum, and Gaskellianum; *vexillarium* and its varieties, *Rex*, *Rougeri*, and *superbum*; *Arthurianum* and varieties *pulchellum*, *giganteum*, *Stand Hall*, *Charlesworth's*, and *Gatton Park*; *Mrs. de Vere Beauclerk* and *Germaine Opoix Westfield* variety.

SECONDARY CROSSES. — *Cypripedium Norma Westfield* variety, *Priam virginale*, *Priam Sedeni*, *Minos Veitch's* variety, *Lowii*, and *Westfield* variety, *Vexill-Id*, *Imogene*, *Statterianum*, *Bella Westfield* variety, *Little Gem*, var. *Sedenii*, *Mrs. Robert Lonsdale* (*Arthurianum* x *Lathamianum*), *Epicasta Westfield* variety (*vexillarium* x *œnanthum superbum*), *Lawrenceanum-Niobe*, *Niobe-Leeanum*, *San-Arthur*, *Thalia punctata*, *Thalia gigantea*, and *Thalia Mrs. Francis Wellesley*, the last-named being the most beautiful of the whole collection, and one of the very finest *Cypripediums* yet introduced.

CULTURE OF CYCLAMEN.

THE propagation of *Cyclamen*, whether species or varieties, is effected by seed, which is never in a better condition for sowing than when freshly gathered. The seeds of hardy kinds should be sown in pots, and be germinated in a cool frame. As soon as the seedlings appear, they should be thinned and be grown in a frame until they are ready for planting in their permanent quarters. A well-drained soil is essential for their success, and a sheltered position, where the plants will be somewhat protected during winter, is to be preferred. All varieties reproduce themselves nearly perfectly true from seed, provided the plants are isolated when in flower to prevent cross-fertilisation with other varieties.

Few plants are better for winter and spring decoration of the greenhouse and the conservatory than the florists' *Cyclamen* (*C. latifolium*), and few subjects produce such a fine display of blossom for the moderate amount of care they require. The seeds are best sown in the autumn, although some cultivators sow them in the spring. I consider August an ideal month for their sowing. An ordinary seed pan should be used, which must be clean and be well provided with material for drainage. Three parts fill the pan with a compost of light, sandy soil that should be pressed moderately firm, well watered, and allowed to drain. The seed should then be sown thinly, and be pressed in the soil, and afterwards thinly covered with light, sandy soil. Place a pane of glass over the seed pan, and germinate the seeds in a temperature of from 55° to 60° Fahr. When the seedlings appear, remove the glass cover, and place the pan on a shelf as close to the roof as is possible, to prevent the plants becoming drawn. When large enough to handle, pot them into thumb pots in a compost of loam, leafmould and sand. Next place them on a shelf near to the glass in a temperature of 55°, and spray them lightly several times a day. By the end of January these small pots will be well filled with roots, when the plants should be transferred to pots of a larger size, using 4-inch pots for preference. The same compost may be used as advised for the first potting, but it should be rougher in texture. When the plants have become established, a temperature of 50° will suffice.

Strict attention should be given to the operations of watering, ventilation, shading, and syringing. I do not advocate heavy syringing overhead, but a slight moistening sufficient to promote a strong, healthy growth.

About the first week in May, a frame with a northern aspect and a coal-ash bottom should be prepared for their reception. A sprinkling of soot and lime over the bottom of the frame will help to ward off worms and slugs, which do much harm to these plants.

After placing them in their new quarters, keep the atmosphere of the frame close for a few days, and shade carefully when necessary. Ventilation must be given judiciously and cold draughts

avoided: in bright weather light syringings of water will be beneficial. By June the plants will be ready for their final potting; pots 5 or 6 inches in diameter should be used, and perfect drainage must be provided. A suitable compost consists of two parts good fibrous loam (in pieces about the size of a Walnut), one part flaky leafmould, and one part old Mushroom manure, with the addition of a little soot, bone-meal, mortar rubble, and sufficient silver sand to keep the whole porous. Never, in any case, use rank manure. Great care should be exercised in potting, for the roots proceed from the base of the fleshy rootstock, and this should be about half covered with soil. Their requirements at this stage consists chiefly in keeping them near to the glass, to prevent weak growth. Apply water liberally and with care. Shade from bright sunshine, and syringe them several

FRUIT REGISTER.

HIGH CANONS APPLE.

THIS is a medium-sized cooking Apple of irregularly ovoid-conical form, truncated at the top, where it is, more or less, five-sided, yellow, slightly flushed with red on the sunny side. The "eye" or calyx tube is deep, inversely conical, open at the top and surmounted by five spreading deltoid-lanceolate hairy, sepals somewhat reflexed at the point. Stamens from the base of the calyx tube, stalk short $\frac{1}{2}$ -inch set in a shallow basin. Flesh firm, whitish, pleasantly flavoured, slightly acid, core-cells axile.

Our specimens were received from Mr. J. Willard, of the Gardens, Holly Lodge, Highgate, who gives the Apple an excellent character. It is not mentioned in the *Fruit Manual*.

trees on the same wall were Easter Baurré, Baurré Langelier, Old Crassane, Grosse Calbasse, and Van Mons's Léon Le Clerc. Singularly there were trees on the north side of this wall of two late ripening dessert varieties, viz., Ne plus Meuris and Jean de Witte, which regularly bore good fruits that ripened perfectly in due season in the fruit-room. Where the climate is too cool in the summer for these late varieties to thoroughly ripen, even on warm walls, it is wise to plant others about which there is no doubt, and as such I would recommend for late use Glou Morceau, Doyenné du Comice, General Todleben, and Marquise, the latter having a melting, very rich and firm flesh; and Princess, a seedling from Louis Bonne of Jersey, large and handsome, and of fine flavour, both raised at Sawbridgeworth by the late T. Rivers; Charles Ernest, Marie Louise d'Uccle, Baurré Bachelier, Baurré d'Anjou, Chaumontel, President Barabé, Josephine de Malines, Monarch, Prince Napoleon, Nouvelle Fulvie, Olivier de Serres, and Doyenné d'Alençon, all of which mature their fruits on walls facing to the south-west or east, anywhere excepting the coldest districts. F. M.

FIG. 58.—CULINARY APPLE "HIGH CANONS."

times a day. About September, remove the plants to an airy house, for by so doing the flowers will last a long time.

Cyclamen may be prepared for cultivation a second year by withholding water and resting them for a time. A system of completely drying the corms in summer was once practised, but this has now been abandoned by all good cultivators. The flowers are generally earlier, and smaller the second year. An excellent system of treating the second year corms is to place them in boxes of leaf-soil about the middle of June, afterwards potting them as they require it.

The Cyclamen is particularly liable to be attacked at all stages of growth by green fly, red spider, and thrip. Fumigating frequently, but not too strongly, will destroy green fly and many of the thrips. Sponging the leaves, or dipping them in soft soapy water, and afterwards in clean water, is the best remedy for red spider. Jno. Norwood, Panshanger, Hertford.

LATE PEARS.

THE notes on various late ripening dessert Pears in the issue of the *Gardeners' Chronicle* for February 2, p. 67, induce me to give my experiences regarding some of the older favourites among the finest varieties of Pears. With regard to Baurré Rance, it may be stated that, away from the more southerly counties of England and Ireland, it is scarcely worth planting as a dessert fruit; at any rate, it is scarcely edible unless grown on a south wall, and it is seldom that a gardener is enabled to spare a place on this aspect for a Pear, however good it may be, other late varieties being as fine in quality, and more certain to afford excellent fruit in an average season. I have known Baurré Rance in Northumberland afford fruits fit for the dessert in about one year in five, although the tree was placed on a south wall, in a garden about a mile from the sea. Other varieties that seldom furnished eatable fruit from

THE ROSARY.

CULTURAL DETAILS FOR MARCH.

MARCH is usually a busy month in the Rose garden, and unless there is another very severe cold snap as obtained some time ago, all the protective material such as straw, litter, or Fern should be removed. The tender and dwarf Tea varieties that are earthed up can remain thus protected till the end of the present month, when the earth should also be taken away. Strong climbing varieties except Teas and Noisettes, in sheltered aspects, can now be pruned, and should have all weak, dead, and useless wood removed, leaving the strong, ripened growths nearly their full length. A few also of the hardiest hybrids and perpetuals can be pruned, and where there is a considerable number the pruning is best done at intervals in batches, allowing an interval of ten days, commencing in the South from now onwards, and in the Midlands and the North a fortnight or three weeks later. In this way a longer succession of bloom is ensured. Roses should be pruned according to their habit of growth; weakly growers should be cut back to within 3 to 6 buds, and others which are more vigorous can have their growths left longer. Bushes with crowded heads should have their middle growths well thinned, removing especially all unripened and weakly wood. Late planted Roses should be lightly pruned the first year. Pillar Roses should have their oldest stems cut right away and their place taken by the strongest rods of last year's growth. Moss, Provence, Hybrid, China, and other summer blooming Roses only require their superfluous old wood removed and thinned in the late summer after they have flowered. The Austrian and Penzance Briars can be treated in a similar manner. In the China section the old wood should be cut hard back, leaving the young ripened wood of the current year's growth intact.

On early-forced Roses there will now be a goodly supply of cuttings. The growing points can be employed for herbaceous grafting, which should now be in full swing. The bottom of the shoot will be the more matured, and this can be used for cuttings, allowing two nodes to each cutting, but where flower buds are showing, nearly the entire shoot can be used for the same purpose. The cuttings can be placed singly into thimble pots that are filled with sandy loam and leaf-mould. A well prepared hot bed outside is the usual place in which to root the cuttings. This bed, when properly prepared and settled, should not be less than 3 feet 6 inches to 4 feet in height, and a foot margin should be allowed all around the frame to admit

of fresh manure being added if required. Before the pots are plunged, place several inches of cocoanut fibre on the surface of the bed to counteract any excess of moisture and steam that may be given off, and if it is still found there is much condensation, afford a little ventilation at the back of the frame, being careful in doing so not to perceptibly lower the temperature, which, when the frame is put on, should not be lower than from 70° to 75°. This temperature should be maintained until the cuttings are rooted, which will take from three weeks to a month. Protect the frames at night time with mats and shade the cuttings from strong sunshine during the day. The treatment of the pot Roses (not grafted plants) will now be chiefly of a routine character. More ventilation must be given with the advance of the season, and the atmosphere must be kept more humid to correspond with increased evaporation. A frequent application of the syringe is desirable to keep down aphids. The potting of grafted plants into 5-inch pots can still be proceeded with until the whole batch is potted. Pot Roses, when nearing the flower-bud stage, should be given liquid and other manures. The following is a list of the most vigorous and free-blooming decorative varieties of Roses. They are classed in their different shades of colour as near as is possible, and are all free-blooming decorative varieties of hybrid perpetuals, except those marked H.T. Scarlet, crimson, and dark red: Beauty of Waltham, Alfred Colomb, Captain Hayward, Marie Baumann, Dupuy Jamain, Abel Carrière, Mme. Victor Verdier, Victor Hugo, Duke of Edinburgh, Duke of Teck, General Jacqueminot, and Prince C. de Rohan. Red and pink shades: Madame Testout, H.T., Capitaine Christy, H.T., La France, H.T., Francis Michelon, Hugh Dickson, Mdle. Eugénie Verdier, Countess Rosebery, Marchioness of Downshire, Mrs. Sharman Crawford, Countess of Oxford, Mme. Gabrielle Luizet, and Victor Verdier. White and blush: Violette Bouyer, Boule de Neige, Margaret Dickson, White Baroness, Marchioness of Londonderry, Alba Rosea, Mdle. Bonnaire, Mme. Lacharme, and Merveille de Lyon. J. D. G.

FOREIGN CORRESPONDENCE.

TENERIFFE.

JUNIPERUS CEDRUS.—I continue to take a keen interest in this rare tree of ours, almost doomed to extinction, and trust that the following practical observations may be welcome to your readers:—

(1) The difficulty of germinating the seeds has been quite overcome by soaking the extracted seeds in plain water for several days (a fortnight). Mr. Correvon, of Geneva, managed to germinate all the seeds I sent him (about 100, which is a great triumph). His idea was to have oxygen in the water. For all practical interests my way of soaking in plain water answers, considering that before use it was quite a rarity to get a single seed to germinate if sown with the berry. I have an idea that the reason why this tree inhabits exclusively the highest peaks of the Canaries is because the snow in winter which covers our highest mountains must have some effect in preparing the berries and enclosed seeds for germination.

(2) My experience with cuttings of this Juniperus is, I think, noteworthy. I took the cuttings from a young tree about four years old, and put two cuttings over a year ago in ordinary soil in the open air in pots. One died after having lived nearly a year, and the other has now roots over one year after planting!

Another lot of cuttings was inserted last February, also in the open air in boxes, but with coarse sand in the soil. A fair number have produced roots, and a few are still alive, but without roots. It strikes me that it could easily be propagated in this way in Government nursery beds in your colonies. From one young tree a good many cuttings could be obtained. At any rate, in the mild climate of Puerto Orotava, with a mean temperature of 65° Fahr., no hothouse is needed to make the cuttings strike roots. George V. Peres.

A PIPE PLANT.

THE idea of being able to grow our own pipes in a limited space in our own gardens is one so novel and likely to be so attractive to gardeners generally, many of whom are patrons of the "weed," that I shall probably be excused for occupying a portion of the valuable space in the *Gardeners' Chronicle* for the purpose of drawing attention to what may become a home industry. The Imperial Commission of Agriculture in the West Indies is reported in the *Agricultural News* of Barbados for December 15 last to be endeavouring to obtain seeds of what we may call the new pipe-plant, for trial in the West Indies. My first acquaintance with the new pipe was made about six or eight months back, when I was shown one which had been brought home by a friend from the Cape. It was described as a South African Calabash, or Gourd, lined with some substance said to be meerschaum. As the smaller Gourds are often used for pipes in tropical countries, I was not specially attracted by this particular pipe, except for its lightness, and I attributed it to the well-known *Lagenaria vulgaris*. More recently, however, in the catalogue of one of the largest of English tobacco and pipe merchants, I found the "South African Gourd pipe" spoken of as being in extraordinary demand in England, so much so that the stocks in the market had run very low, but at the present time regular consignments of genuine Calabash pods (so-called) were arriving apparently in the raw state, as the pipes are said to be "hand finished" in this country. Externally, the pipes have an exceedingly smooth surface and a pale yellow colour, closely resembling meerschaum. They are chiefly lined with what is described as "manufactured pressed meerschaum," which is

FIG. 53.—THE CALABASH PIPE.

probably plaster of Paris, and mounted in silver. They vary in price from 4s. to 30s. each, according to the nature of the mounting and the lining, the more costly pipes being said to be lined with real meerschaum. The advantage of these pipes over the ordinary wood pipes is said to be their porous nature, so that the nicotine is readily absorbed, thereby ensuring a clean, cool, dry, and consequently a hygienic pipe.

To turn to the commercial aspect of this new article, it will be interesting to quote the following from the *United States Monthly Consular Reports* for November, as given in the *Agricultural News* before referred to. The writer says: "Smokers who have used the Calabash pipe agree that it gives a special softness of flavour that pipes of no other material offer. I believe this to be so, and that the demand for such a pipe in the American market would be very large. The Calabash should be grown in the United States, and, to this end, seed has been promised, which, when supplied, will be transmitted to the American Department of Agriculture. The Calabash pipe industry is proving a very remunerative one in Cape Colony, both to the growers of the Calabash and to those engaged in making it into pipes, and also to the retail sellers. It grows in certain sections of Cape Colony with little difficulty, but seems to demand a very hot and dry climate, with rain at the right season of the year, in order to reach perfection. The curved stem end of the vegetable forms a light and appropriate shape for

pipes. It colours like meerschaum, and will take a high polish. The duration of the life of one of these pipes is about the same as that of a French briar-wood pipe. The usual lining is plaster of Paris, called by the trade meerschaum. A cheap grade is lined with tin. These pipes sell from 97c. to \$2, according to type of finish. Pipe mounting and fitting being cheaper in England than in Cape Colony, large shipments are made to England for mounting and returned for sale. The industry is being crippled in South Africa by the growers refusing to sell the seeds of the Calabash. It is extremely difficult to obtain them from any source. The crop last year was estimated at 60,000, and this year (1906) at about 150,000, but next season's prospects are not so good." It is further stated that 20,000 of these Gourds have recently been purchased by an American business man from Cape Colony farmers for exportation—presumably in incomplete pipe form, to the United States.

Whether the pipes are really made from a Gourd—that is, from a Cucurbitaceous plant, and, if so, from *Lagenaria vulgaris*, or from the true Calabash (*Crescentia cujete*) I am unable to say, as I have not had an opportunity of seeing the fruit in the rough or natural state. The probability of its being *Lagenaria* is very great, as these Gourds are commonly used in many parts of Africa, as well as in other tropical countries, for bowls, spoons, and other domestic articles, and they can be fashioned into any form by growing in moulds, as is done in China and Japan in the formation of ornamental water bottles. So that, notwithstanding all the pipes at present in the market are of the shape we figure, various devices may suggest themselves to the coming pipe-grower, whether in Cape Colony, America, the West Indies, or in England. John R. Jackson.

THE COUNTRY GARDEN.

Know what you expect to get, and what you want from each section or portion of the garden, and where possible let one portion help another. For instance, the character of a walk may enhance the beauty of the part of the garden to which it leads; but too often it is absolutely indifferent to it.

You must, if the garden be a large one, secure varied features. It is not enough to vary the kinds of plants in the different borders as I suggested in my last article; but, also, different phases of gardening must be represented. I have seen a moderate sized and decidedly uninteresting garden gain greatly in character, in interest, and in boldness of effect, by turning a small portion of it into a well designed and well placed rock-garden. It meant a great deal in the general bold picturesqueness of the whole. It meant a new character of plant-life, with distinct and characteristic habits of growth, and the introduction of bold and artistic setting. Why, the setting alone was worth a good deal, and in this case the position chosen for the site gave this its full value.

Other features suggest themselves—the Rose garden, the Fernery, the bog garden, the water garden, the wild garden, the woodland garden—and, I would add, whether one or all of these come to be represented, make a vigorous attempt to give to each one its own true character. Do not let them be either one thing or another, but let each one be bold and distinct. Of course, the bog and the water garden may be more or less combined, and the woodland garden will also, probably, be a wild woodland garden—well and good—these things have congruity. The error comes in when we try to make the rock-garden partake of the nature of a bit of formal bedding, or when a Fernery and rock-garden are combined. The aspect that suits the Alpine and other rock-loving plants is not that which we would choose for the majority of our Ferns, so that such a combination lacks congruity and all sense of fitness. There are

certain shade-loving plants—the Foxgloves, some of the hardy Primulas (Cyclamens), and such subjects as Woodruffe, and some of the early-flowering bulbous plants that may be introduced in the Fernery with charming effect, especially if it be a woodland Fernery; but great discretion needs to be used, and flowering subjects should only be introduced just so far as they enhance the beauty of the Ferns. In a Fernery the Ferns should be the dominant feature. I should not have ventured to call attention to points such as these had I not been from time to time struck with them, and even in large and important gardens.

As a character-giving and decorative feature, I look upon the rock-garden as one of great importance. The bolder and simpler the ground plan and general design, so much the more effective, and it adds greatly to its artistic possibilities if a pathway can run through it, and not merely beside it. To have the same character of planting on both sides of a pathway makes for picturesqueness and a sense of delightful repose and harmony. This applies, I venture to think, to all portions of the garden. A pathway, for instance, with a flower border on its one side and grass on the other, has far less beauty, and lacks a sense of completeness, than one that gives us its quota of colour on both sides. The grandest effect in the rock-garden is usually from the early spring to the end of June or thereabouts. After that, many rock-gardens become rather shabby and forlorn for many months. This, surely, is to be deplored, for while the summer finds the rest of the garden at its gayest, the lack of brightness here is the more noticeable. Some of the best of the late dwarf Campanulas, many of the Sedums, and such a striking subject as *Potentilla nepalensis*, go far to furnish the rock garden with summer colour. And besides these plants of perennial growth, much can be done by growing some annual plants that are especially adapted to this use. Among the most treasurable is *Mesembryanthemum tricolor*, especially for some hot sun-smitten position. It is a gem of the first water, and it is worth while to make at least a couple of sowings at intervals of a fortnight. Another plant that can be strongly recommended for this use is *Oenothera triloba*, syn. *O. rhizocarpa*, and there is the extremely dwarf *Ionopsidium acaule*, that would seem to have advanced this last season or two very greatly in public favour. There is also a bedding plant that may be introduced to the rock-garden to yield a brilliant patch of colour from June until December—I mean the *Gazania splendens*. It seems to take on a new beauty in such a position, and is very effective. With a little care the rock-garden may be as beautiful as the rest of the garden during the late summer and autumn. *Practical Gardener.*

ODONTOGLOSSUM WATTIANUM PRINCEPS.

THE illustration at fig. 60 represents a flower of this remarkable variety of the cross between *O. Harryanum* and *O. Lindleyanum*, which was first imported as a natural hybrid, but which in the present instance was home-raised by Messrs. Sander & Sons, of St. Albans and Bruges, who showed the plant at the meeting of the Royal Horticultural Society, February 13 last, although it was not submitted to the Orchid Committee. The flower illustrated is of natural size, the sepals and petals were pale yellow heavily blotched with chocolate-purple. Lip white with violet markings at the base. In our issue of October 20, 1900 (p. 286), we illustrated the first variety of this cross raised in the gardens of De B. Crawshay, Esq., Rosefield, Sevenoaks, who thus proved the correctness of the reputed parentage of the original natural hybrid.

NOTICES OF BOOKS.

MITTEILUNGEN DER DEUTSCHEN DENDROLOGISCHEN GESELLSCHAFT, 1906 (Transactions of the German Dendrological Society). Editor, Graf v. Schwerin, President of the Society. Publisher, L. Beissner, Royal Garden Inspector, Bonn-Poppelsdorf.

We have in this account of the doings and varied activities of the Arboricultural Society of Germany for the year 1906 a great mass of most useful information. The "mitteilungen" consist of articles written on trees, chiefly of exotic origin, that have been tried in various parts of the country to ascertain their commercial value, hardiness, durability and good quality. The first paper in the volume is concerned with

quite hardy in Germany. *Prunus serotina* is a failure in peaty and distinctly wet soils, but succeeds in any other, either wet or dry. The tree is recommended for its use in house carpentry, for its hardness and handsome light reddish brown colour; and for these reasons it is imported in large quantities. The advantages of growing the tree in Germany are the lessening of the importations; the possibility of turning poor, dry, sandy soils into good paying ones; filling gaps occasioned by drought in existing woods by a strong-growing, valuable tree; and affording abundant food for useful birds. The plant is obtained from imported seeds, and as the tree fruits at an early age home-grown seeds will be soon available. The article finishes with a brief account of other species of *Prunus*.

A very interesting list of new and rare shrubs

FIG. 60.—ODONTOGLOSSUM WATTIANUM PRINCEPS.

Prunus serotina of Ehrhardt, and is the work of Fritz Graf von Schwerin, who, *en passant*, corrects the faults into which various authorities have fallen in confusing this species with *P. virginiana*, which, on account of its red fruits, has been named *P. rubra* in some gardens. He furnishes a full description of the tree, and a figure is given of a specimen growing in the Palace Garden of Rastede, in Oldenburg, which is 76 years old, and has a height of 15 metres, and a stem of 2.35 metres at 1 metre high. Although the seeds which have reached Germany come from the more southern United States of North America, there has been no known case of a tree of this species having been injured by frost, and the tree may be as capable of acclimatisation as, for example, the Grecian *Acer Heldreichii*, which, in spite of its southern habitat, is

growing in the Botanical Garden at Darmstadt is supplied by the Grand Ducal Garden Inspector Herr A. Purpus. Among these are some that are unknown in gardens in this country, three of which are illustrated, viz., *Euptelea polyandra* (Siebold and Zuccarini), a bush with metallic, glistening foliage. It belongs to the Trochodendraceae, is native to Japan, and is hardy at Darmstadt. Further, *Euonymus planipes* (Köhne), a grand ornamental shrub from Japan, with long-stalked fruits of a red colour; and *Fallugia paradoxa* (Endlicher), collected by C. A. Purpus in the San Francisco Mountains, Arizona, a charming bush which flowers the entire summer. The flowers are white, and resemble those of *Dryas octopetala*. An excellent subject for planting on sunny rockeries.

Mr. John Booth replies at length to the

question put by the president in 1905 concerning the behaviour of ten species of exotic forest trees. Space allows us to mention only the names of the species he favours: Douglas Fir, Weymouth Pine, *Juglans nigra* (American Walnut), *Prunus serotina*, *Carya alba*, of which tree an example 100 years old exists in Carlsruhe, and there are others elsewhere; *Quercus rubra*, *Populus canadensis*, some of the *Acacias*, and the Tulip tree.

A most interesting and instructive paper is that furnished by Herr. T. J. Seidel on the crossing, acclimatisation, and cultivation of the *Rhododendron*. As is pretty well known, the severity of the winter, and the heat of summer in Germany at any distance from the sea coast, and in some parts (as at Grüngräbchen) night frosts throughout the summer months, make the cultivation of the finer species and varieties of *Rhododendrons* an impossibility out of doors. There is not alone the winter's cold to contend with, but furious winds, and, consequently, only varieties should be sought for in the crosses which possess strong leaf-stalks and small thick leaves, and of such good species and varieties are found in the Caucasian *R. Smirnowii* and *R. arboreum-Catawbiense* hybrids. Mrs. Miller and Jay Gould belong to this last-named class. The hybrids from *R. Smirnowii* are absolutely hardy. *R. Catawbiense* hybrids have likewise proved hardy in a garden at Schmiedeberg on the Riesengebirge, at a height of 1,500 metres, withstanding cold and storms, and flowering beautifully in the spring. A great mass of information regarding methods to be adopted in raising hybrids suited to the climate inland is afforded. The warm sun on bright days in winter and the succeeding frosts at night do more harm than cold alone; and those species apparently hardy, which make early growth, suffer from late spring frosts.

Conifers are treated at some length by no less an authority on this family than Herr. L. Beissner, who takes as his first note Mr. A. C. Bartlett's communication respecting *Picea Morinda*, in *Gardeners' Chronicle*, 1905, p. 395, and of the note on *P. Morindoides*, *Gardeners' Chronicle*, 1906, p. 132, in which the points of difference in the two species are commented upon. He then goes seriatim through many Caucasian species of *Abies*, *Junipers*, *Taxus baccata*, *Biota*, *Pinus*, *Picea excelsa* varieties, giving the names of places where the trees are to be found. Descriptions of numerous new species of Conifers are given briefly, and authorities carefully acknowledged, and special thanks are expressed for the valuable assistance afforded by the Editor of this journal.

We have a chapter on hardy species of *Rhus* by Herr. L. Graebner, together with a coloured map of the habitats of the North American species, and photographic illustrations of several of the more attractive species.

The geographical distribution of American *Cupuliferæ*, and characteristic forest trees, and a mass of brief communications on arboricultural matters form the concluding portion of the book. F. M.

THE MODERN CARNATION.—How to Grow and Show it. By Hayward Mathias and P. Smith. Price 3s. 6d. Burnley: Horticultural Printing Co.

The authors offer as justification for the publication of this little manual that it supplies "small items of routine hitherto considered unworthy of notice" in the numerous books on the *Carnation* which have appeared in recent years. There are nine chapters in all, of which those on "Growing for Exhibition," "Dressing and Staging," and "Americans" are most worthy of attention. It is a book that one can recommend to the novice who is ambitious to grow blooms for exhibition, and there is a kind of freshness in the authors' style that he will find to be fascinating.

The Week's Work.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir Trevor Lawrence Bart., Burford, Surrey.

Anæctochilus.—Amongst Orchids now about to start into growth are the handsome leaved *Anæctochilus*, which include such varieties as *A. Dawsonianus*, *A. Sanderianus*, *A. Rollissonii*, *A. petola*, *A. setaceus*, *A. Lowii*, *A. Roxburghii*, *A. striatus*, &c. The flowers are insignificant and of no importance, but the marvellous beauty of the leaves entitle these plants to the consideration of those who appreciate lovely plants. For several months past these species have been in a dormant state, but now the leading growths are starting to develop fresh leaves, the plants will require to be kept slightly moist at the root. Immediately new roots appear, the leading growths may be severed to about 3 inches in length, and be potted singly into small pots, using a mixture of chopped sphagnum-moss freely intermixed with small crocks and silver sand, afterwards plunging the pots as closely together as possible in a large pan filled with sphagnum-moss. A bell-glass of a suitable size with a hole at the apex may be placed over them, affording air by tilting the glass a little on all favourable occasions. At Burford we find these severed pieces grow very well when planted in the surface moss of the *Aërides*, *Saccolabiums*, &c., which have lately been re-potted, and throughout the growing season they share the same treatment as is afforded to those plants. After taking off the leading growths, the back pieces, if laid upon some damp moss, will in time produce young plants.

Evergreen Calanthes.—Such plants as *C. veratrifolia*, *C. Masuca*, *C. Dominicana*, &c., which are now in full growth and sending up flower spikes, require considerable water at the root, and an occasional application of weak liquid cow-manure will be beneficial if the pots are well filled with roots. These remarks are also applicable to such species of *Phaius* as *P. bicolor*, *P. Blumei*, *P. grandifolius*, *P. Norman*, *P. Marthæ*, &c. All these plants thrive best in a shady part of the *Cattleya* house. The cooler growing varieties as *Calanthe japonica*, *C. citrina*, *C. discolor*, *C. natalensis*, *C. curculigoides*, &c., require a similar position in the intermediate house, which is at all times several degrees cooler than that of the *Cattleya* division. Whilst growth is being made they must be well supplied with water at the root.

Bletia hyacinthina and its variety *alba* require similar treatment to that recommended for *Calanthes*, but should be elevated to a lighter position in the house, and, being deciduous, require a decided rest during winter. The new growths are now pushing up, and if necessary the plants may be re-potted. They grow freely in well-drained pots in a mixture of fibrous loam, adding a little chopped sphagnum-moss, small crocks, and coarse sand.

THE HARDY FRUIT GARDEN.

By J. MAYNE, Gardener to the Hon. MARK ROLLE, Bickton, East Devon.

Watering.—It may appear full early to write on such a subject, but comparing the first seven weeks of the present year with the corresponding ones of 1903, rain equal to only a third has fallen this year, and this seems pretty general. December last was also far from being a wet month. Taking these facts into consideration, it will be wise to test the borders in which Peach and Nectarine trees are growing, for these fruits quickly feel the effects of a dry root medium, and this is often the cause of their dropping many of their buds. Should the borders be found to be dry, afford a thorough watering, and repeat this in a month's time, if the rainfall still continues to be slight. Much will also depend upon the quarter from which the rain comes, and whether the borders have received much or little of the moisture that has fallen. Other kinds of fruit trees do not suffer in such a marked degree as do those mentioned above, yet all stone fruits growing against warm positions on walls will be benefited by a good watering in such a dry season as this.

Blossom protection.—The return of milder weather is causing the sap to ascend, and the

tiny pink and white blossom buds of the *Apricot* will soon be expanding, and especially so in the warmer counties. It is absolutely necessary, therefore, except in the case of trees in a few favoured spots, to erect some sort of protection sufficient to ward off hail and sleet, and to break the force of the cold-cutting winds usually experienced during the present month. *Apricot* trees growing against cottages, farm buildings, &c., are often found carrying good crops of fruit, whilst trees on garden walls, carefully protected, have but few. The warmer and drier surroundings of trees in the first-named spots probably accounts for this extra cropping. Removable coverings of some material such as tiffany are by far the best means of protecting fruit trees, but excellent crops of *Apricots*, *Peaches* and *Nectarines* are often had by merely protecting the blossom with one or two thicknesses of ordinary twine netting, erected as soon as the first few flowers open, and allowed to remain until the foliage acts as a shelter for the tiny fruits. Whatever protection is afforded, it must be kept clear of the trees, and should hang from a coping at the top of the wall, or from some similar projection: an 11-inch deal board, placed at an angle of 25° to 30° from the top of the wall, will answer the purpose well. Pieces of quartering or stout stakes should be placed every 10 feet, with the foot 4 feet from the base of the wall, and allowed to rest at the top against the coping. Light branches of *Spruce Fir* are sometimes tied on Plum and Pear trees trained against walls, but they must be put on very lightly or more harm than good will result. Bush and pyramid-trained trees in the open are sometimes protected with scrim canvas or hexagon netting.

THE KITCHEN GARDEN.

By WILLIAM HONKES, Gardener to C. COMBE, Esq., Cobham Park, Surrey.

Onions.—The ground intended for the sowing of the spring crop of this vegetable should have been well manured at the time of digging, and should now receive a dressing of soot and salt, which should be well worked into the soil. The seed should be sown in shallow drills, drawn from 9 to 12 inches apart, according to the general size of the bulbs of the varieties to be sown. Such standard kinds as *Ailsa Craig*, *Bedfordshire Champion*, *James' Keeping*, *Brown Globe*, *Magnum Bonum*, and *Improved Queen*, for pickling, may be recommended. Onions that were sown in heat in January or early in February will soon require transplanting into other boxes or into a frame close to the glass. This shift, though not absolutely necessary, will give better results than if the seedlings are planted from the seed boxes.

Parsnips.—If seeds of these have not already been sown, sow at once in drills 18 inches apart on ground that has not been recently manured such varieties as the *Student* and *Hollow Crowned*. If the land was lately manured and the material was deeply buried, it may be used for *Parsnips*, but if the manure is near to the surface, the roots will become branched, and a very unsatisfactory crop result.

Leeks and Parsley should also be sown.

Globe Artichokes.—As the weather becomes milder, remove the litter that was placed about the plants for protection, for the plants should now be exposed to all the light and air possible to strengthen the suckers before they are required for planting by the end of the month. In the south a second planting might be made early in May, and if the stools are kept well watered throughout the summer they will furnish a supply of good "heads" throughout the autumn, after the earlier ones are finished. This is an excellent plan of increasing the stock of these plants, and with ordinary care it is generally successful. The suckers should be planted on liberally prepared ground 3 feet apart in the rows, leaving a space of 4 feet between the rows.

Seakale seeds should be sown during the present month. If the plants are intended for filling gaps in existing beds, the seeds should be sown in rows 1 foot apart, but if required to form a bed where they are sown they should be inserted in triangular patches of three, 2½ feet apart each way, and on rich light ground. Young plants will often give good results the following winter if forced steadily, and towards the end of the season.

PUBLIC PARKS AND GARDENS.

By W. W. PETTIGREW, Superintendent of the Parks and Open Spaces in the City of Cardiff.

Springtime.—The most interesting time of the year in the public park, as in the private garden, is fast approaching, and visitors will soon have many things to attract and please them, as each day adds a little more life and brightness to park scenery. Hazels and Willows, early-flowering species of Erica and Snowdrops—which, in this part of the country, are now at their best—all give their quota of beauty and indicate that springtime is at hand. The Crocus will soon be with us again, and in a very few weeks more we shall be in the midst of all the glories of Daffodil time. After the dark days of winter the appearance of the spring flowering plants are the more appreciated by visitors, who find in them a great source of delight. For this reason spring-flowers should always be made as prominent a feature as possible in every park suitable for the purpose. Since it has become customary to naturalise these in swards, among trees, and in the waste parts of our pleasure grounds, the beauties of parks, &c., in springtime have been greatly increased. The formal designs, with their masses of one or two colours, become almost distasteful when compared with the same kind of plants growing haphazard among grass. In small, formal gardens, where the grass is always kept closely cut with a mowing machine, it is, of course, quite out of the question to naturalise bulbs in the sward, so, rather than do without them altogether, it is very much better to grow them in beds and borders.

Naturalised spring-flowering plants need not necessarily be confined to such parts of the grounds as are covered with grass. I have seen places which in summer are nothing but hickets of brambles and such-like plants, in springtime developed into beautiful pictures by being clothed with Bluebells (*Scilla*), Wild Anemone, and Anemone fulgens. To permit these being seen and appreciated it is necessary, about the end of December, to clear away all bramble and other vegetable growths which have accumulated during the year. This clearance also enables the Anemones and Scillas to become thoroughly matured before the ground is once more overgrown with vegetation. Autumn is the season for planting the bulbs, but the early part of the year is by far the best time for considering and noting any alterations or additions that may be necessary to make to already existing groups of bulbs, and the selection of suitable sites for new plantations of them. Loping ground is most suitable for the naturalisation of spring-flowering plants. A fairly long accession of bloom can be maintained in grass and on the rougher and "unkept" portions of the park by using such plants as Snowdrops, crocus, Muscari, Daffodils, Anemone fulgens, cillas, and Tulips. The latter, on account of their brilliant colours, form beautiful subjects for naturalising, but as they deteriorate more quickly than any of the other plants mentioned, they require renewing very much oftener.

THE FLOWER GARDEN.

By A. C. BARTLETT, Gardener to Mrs. FORD, Pencarrow, Cornwall.

Annuals.—A sowing of Shirley Poppy should be made at the first opportunity in the open ground, selecting a warm spot and a not too rich soil for their reception. If sown in over-crowded ground the plants will form leaves at the expense of the flowers, which will be fewer and inferior in colouring. As soon as the seedlings are large enough they should be thinned to at least 5 inches apart.

A first sowing of Mignonette should also be made on a warm border, paying due regard to the thinning of the plants as they grow. Successional sowings should be made of both the above-named plants. Other annuals which may now be sown out of doors, either for a border display, or for supplying flowers for cutting, include several forms of Cornflowers (*Centaurea*), *Odontias* (the newer double rose-coloured variety *hamini* should not be overlooked), *Scabious*, *veet Sultans*, *Calliopsis*, annual *Chrysanthemums*, *Lavatera trimestris*, and a selection of ornamental grasses. For furnishing a pretty splay on a dry, sunny bank, few things equal *Eschscholtzias*. Choose a fine day for the wing of the seed and prepare a good tilth,

remembering that "the hastening tiller often reaps a bad harvest." When the seedlings are up ply the hoe freely, and rigorously thin out the young plants, for annuals are never seen at their best when grown thickly.

Sow in heat seeds of such plants as African and French Marigolds—the dwarf Legion d'Honneur is valuable either for a groundwork or as a bordering in beds of *Lobelia cardinalis*; *Nicotiana*, in variety, *Phlox Drummondii*, *Antirrhinum*, Stocks, Chinese Asters, *Dianthus*, *Chamaepeuce*, &c. Unless ample room is available, it will be wise to defer the sowing of Zinnias for a few weeks, for if these plants suffer a check, either from a too low temperature or from neglect of transplanting, they will not thrive. A sowing should also be made of such perennials as *Gaillardia*, *Campanula pyramidalis*, and *Papaver orientale* hybrids, to produce plants for flowering next year.

Tuberous Begonias should now be started into growth by placing them in a warm house. The tubers may be placed closely together in boxes of light soil, and, as they grow, they may either be potted singly or be planted well apart in boxes containing suitable soil. Seeds of the same plants should be sown now on the surface of fine soil in seed pots. Place the seed pans in a brisk bottom heat, and shade with pieces of clouded glass.

Cannas, Dahlias, &c.—The stock of these plants should be overhauled, and any varieties which it is especially desired to increase may be brought into a warm house. The main stock of these plants may be dealt with a few weeks later.

Christmas Roses (Hellebores).—Now that the flowering of these plants is over, the frames placed to protect the blooms should be removed. Stir the surface soil about them with a hand-fork, remove all weeds, and apply a good top-dressing of well-rotted manure. The present is a suitable time to plant *Hellebores*, and as these plants resent frequent disturbances at their roots the work should be thoroughly well done, and the soil deeply dug and enriched with cow manure. When transplanting large clumps of Christmas Roses it is advisable to divide them and to discard the weakened central portion, and to plant only the outside crowns, keeping them somewhat above the level of the soil in planting. [See also p. 84.—Ed.]

PLANTS UNDER GLASS.

By J. G. WESTON, Gardener to H. J. KING, Esq., Eastwell Park, Kent.

Allamandas.—If not already taken in hand, these plants should be at once pruned, cutting every growth back to well-ripened wood. When this has been done, and if the plants are grown in pots, they should be turned out, and after reducing the "ball" as much as is thought necessary, subject the roots to a thorough soaking in a tub of water. Remove it from the water and let all the water perfectly drain from the roots before repotting them firmly, in a compost consisting mainly of good loam, mixing a little well-rotted manure with it. Place the newly-potted plants in a light position in the stove. The roots will not require to be watered until growth commences, but the syringe may be used freely, and when the plants are in full growth, copious supplies of water will be necessary, and also manurial stimulants, to keep the plants healthy and vigorous under the strain of continuous flowering during the summer and autumn seasons. If the plants are established in narrow borders or large tubs, take off some of the top-soil, and apply a top-dressing of loam and manure, afterwards mulching with some cow manure if considered to be practicable. Cuttings of *Allamandas* will root very readily if taken when the young shoots are about 6 inches long, and placed in the propagating frame.

Clerodendrons.—The deciduous section of *Clerodendrons*, of which *C. Balfouri* is about the best, should be pruned and treated in much the same manner as recommended for *Allamandas*, subsequently potting or top-dressing the plants as they may require. *C. fallax* is the best shrubby variety, and may be propagated with ease, either by cuttings, or from seed. The plants should be grown in the stove on a shelf near to the glass, in order to keep the growths short-jointed. These young plants, if attended

to in the matter of re-potting when required, will make good plants in one season, and produce nice heads of bright scarlet flowers in the autumn. This variety should not be dried off in the winter to the same extent as *C. Balfouri*, but rested in a somewhat cooler atmosphere and watered very sparingly, till it is time for the plants to start into growth in spring, when they may be re-potted and cultivated into large specimen plants.

Gardenias.—The main batch will now be showing bloom, and may be stimulated at regular intervals with a "pinch" of some good artificial manure. See that the plants do not suffer from lack of water at any time, as this would probably cause the buds to turn yellow and fall off. Examine the plants carefully for insect pests. If mealy-bug or scale once get established, they will be difficult to eradicate. Paraffin emulsion is a capital preparation for cleaning *Gardenias*, *Stephanotis*, and similar plants.

Bougainvillea glabra, having been pruned and cleaned, will now be growing strongly. Re-pot any plants it is desired to grow into large specimens, and if increase of stock is desired, cuttings may be taken of the young shoots, and inserted in light sandy soil, and placed in the propagating pit.

FRUITS UNDER GLASS.

By ALEXANDER KIRK, Gardener to J. THOMPSON PATON, Esq., Norwood, Alloa, Clackmannanshire.

Early Pines should still be allowed a steady bottom-heat of 85°, and plants which are now starting into growth and the more forward ones that are showing their fruits will require careful watering. Keep them moderately moist at their roots, and on no account allow them to become dust dry. As the days lengthen, and the sun's rays become more powerful, a higher temperature of from 75° to 80° should be maintained in the pits at night time. Allow a little ventilation when the weather is favourable. Damp the paths three or four times daily in order to produce a moist atmosphere, and close the pit when the temperature falls to 90°. Later plants intended for successional fruiting should have the temperature of the house in which they are cultivated increased to 65°, with a bottom-heat of 70°. Open the ventilators slightly daily, and maintain a humid atmosphere in the pit, remembering that the warmer the weather is the more moisture will be absorbed and evaporated. Attend to autumn-potted suckers, and turn them out of their pots, and if they are found to be well rooted, re-pot them in larger pots, using as a potting medium turfy loam chopped into small pieces. When re-potting is finished plunge the plants again in a bottom-heat of 76°.

Peaches and Nectarines.—These fruit-trees should be cautiously forced during cold, sunless weather. For the present the temperature should not be allowed to exceed 55° to 60° at night time, with, including sun heat, 10° to 15° higher by day. These temperatures will suffice until the fruits reach their second swelling stage. Admit air daily by the top ventilators whenever the weather permits. Syringe the trees during the morning only, as moisture lying about the house late in the day is favourable to the growth of mildew, but evening syringing may be permitted when the temperature is very high. Disbud forward shoots and thin the fruits by degrees. Test the border, and if it is found to be dry, give a good watering with tepid manure water not too strong.

Tomatoes.—Plants of early batches in pots should now be given a top-dressing of loam, leaf-mould, and a handful of plant food, well mixed together. Maintain a temperature of 65° by night time, and 70 to 75° by day in the pit in which early Tomatoes are grown, and as the days lengthen, increase the amount of ventilation, to ensure sturdy, short-jointed growth. Seedling plants should, if not already done, be potted into thumb pots, using a compost of fresh loam, leaf-mould, with a little sand added. Place the soil in the pit to warm before it is used. Plunge the pots in a gentle bottom heat, until the seedlings have rooted in the compost, when they must be removed to a shelf near to the glass, where they can remain until they are transferred to larger pots or boxes. Make another sowing for a later supply. Place the seed-pan in a gentle bottom heat, in which the seeds will soon germinate.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

Illustrations.—The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY, MARCH 2—
Soc. Franç. d'Hort. de Londres meet.
German Gard. Soc. meet.

TUESDAY, MARCH 5—
Roy. Hort. Soc. Coms. meet (no general exhibition).
Scottish Hort. Assoc. meet.
Nat. Amat. Gard. Assoc. meet.

THURSDAY, MARCH 7—
Linnean Soc. meet.
Manchester & North of England Orchid Soc. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—40°1'.

ACTUAL TEMPERATURES:—
LONDON.—Wednesday, February 27 (6 P.M.): Max. 49°; Min. 43°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, February 28 (10 A.M.): Bar., 30·6; Temp., 49°; Weather—Dense fog.

PROVINCES.—Wednesday, February 27 (6 P.M.): Max. 46° Bury St. Edmunds and S.W. Ireland; Min. 42° Bristol.

SALES FOR THE ENSUING WEEK.

MONDAY—
Roses, Azaleas, Liliums, Border Plants, &c., at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.

TUESDAY—
980 cases Japanese Liliums, also Miscellaneous Bulbs and Plants, by Protheroe & Morris, at 12.

WEDNESDAY—
Border Plants and Bulbs, Azaleas, Rhododendrons, Palms, Liliums, &c., at 11; Roses and Fruit Trees at 1.30 and 4; at 67 & 68, Cheapside, E.C., by Protheroe & Morris.
Plants, Roses, and Lilies, at Steven's Rooms, King Street, Covent Garden, W.C., at 12.30.

THURSDAY AND FRIDAY—
The "Shirley Grange" Collection of Orchids, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.

FRIDAY—
Azaleas, Perennials, Hardy Bulbs, Liliums, &c., at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.

The West Indies.

The last mail has brought us information which we were eagerly awaiting from Jamaica, Barbados, and Trinidad. So many of the participators in the Agricultural Conference, such as Sir Daniel Morris, Mr. Fawcett, Mr. Hart, are so well known in the home country, and some of them are so well known to our readers as contributors, that anxiety was naturally felt on their behalf. Happily, we are enabled to say that they escaped injury.

The President (Sir Daniel Morris) and representatives of the sixth West Indian Agricultural Conference, including delegates from Barbados and other West Indian islands and from British Guiana, it appears, arrived at Kingston, Jamaica, in the Imperial Direct West Indian steamship "Port Kingston" at daybreak on Friday, January 11, when they were met by His Excellency the Governor, the members of the Reception Committee, and a large number of the principal officials, men of business, and planters of the Island.

Arrangements had been made for a number of excursions to various parts of the island. One party paid a visit to St. Catherine to see the Banana, Rubber, and Citrus cultivations and the Cassava starch factory at Eltham Park. The Vere district was visited by another party, where opportunities were obtained of seeing Banana

cultivation under irrigation, and the Cotton cultivation of the Vere Estates Co., Ltd. After the Sugar works at Money Musk had been inspected, the party proceeded to the Citrus grove of Dr. Tillman, at Camden, which is probably the best of its kind in the West Indies. On the return journey the representatives were able to see the new central Sugar factory which is in course of being erected at Parnassus.

On Monday, January 14, the Conference was opened at the Old Mico schoolroom in Kingston by His Excellency the Governor, Sir Alexander Swettenham, K.C.M.G., who expressed his great pleasure in welcoming to Jamaica the Conference delegates and the influential and distinguished company brought out from England by Sir Alfred Jones.

Sir Daniel Morris then delivered his presidential address. He said it was a source of satisfaction to him that it had been possible to arrange for this Conference to be held in Jamaica, where he had spent some of the best years of his life, and in which he continued to take deep interest. Probably, in no part of the tropics could be found such diversified industries as existed in Jamaica, and it was, in consequence, singularly favourable as a meeting place for those interested in agriculture.

In the course of a review of the agricultural conditions of the West Indies since the last Conference, held in Trinidad in January, 1905, the President stated that progress was being made in every direction. New industries were being added, and old industries were being revived and developed. Referring to the general anxiety felt throughout the colonies where Sugar is a staple, as to whether the Brussels Sugar Convention was likely to be continued, he announced that after careful consideration he had decided to appoint a committee consisting of representatives closely connected with the industry, which would prepare replies to certain pertinent questions. Attention was also drawn to the position and prospects of West Indian Sugar in the Canadian market. This was followed by a review of efforts to extend the cultivation of Cacao and Citrus fruits in Jamaica. The value of Cacao exported from Jamaica in 1906 was £75,000; of Citrus fruits £99,689.

In regard to the Cotton industry, the President pointed with reasonable pride to the rapid progress that had been made during the last four years. There were now 18,000 acres in the islands under cultivation in Cotton; of this, 15,000 acres were planted with the best varieties of Sea Island Cotton that commanded the highest prices on the English market. The value of the Cotton lint and seed exported from the West Indies was estimated at £200,000. References were also made to the Rice industry of British Guiana, now of the annual value of about £218,000, and the cultivation of Rubber trees in British Guiana, Trinidad, and Tobago; also to the prospects of extending the Jamaica Tobacco industry and of the preparation of Cassava starch on a commercial scale.

In acknowledging the vote of thanks proposed by the Archbishop of the West Indies, Sir Daniel Morris referred to the valuable and loyal services rendered by Dr. Francis Watts, C.M.G., Mr. J. R. Bovell, F.L.S., and the other officers of the Department.

The business of the Conference was then proceeded with, Mr. Cousins and Dr. Watts reading papers on seedling Sugar canes. Mr. Bovell was addressing the Conference on the same subject, when the proceedings were brought to an abrupt conclusion by the fearful earthquake that occurred. Barbados papers contain full accounts of this appalling catastrophe, details of which need not be repeated here. It may be merely stated that Mr. Bovell was dealing with statistics "when

there came a rushing sound as of a troop of cavalry passing a neighbouring street, which changed to the roar of a train entering a tunnel. Then the floor began to shake, to rise up, to heave. The whole building oscillated violently." The subsequent details are too harrowing for repetition. Sir Alfred Jones placed his ship, the "Port Kingston," at the disposal of the authorities, and it was made use of as a hospital.

Sir Daniel Morris and many members of the Conference also took refuge on the ship. Sir Daniel, who had given what assistance he could on the Monday night (January 14), exhibited characteristic British tenacity by proposing to resume the proceedings of the Conference on the steamship on the Wednesday morning (January 16), but naturally this was found impracticable, although on the following Saturday the business was actually resumed on board the ship as she was proceeding with the delegates on the way back to Barbados. Papers on the Cotton industry in the various islands were read, and it was recommended that Cotton should be grown in rotation to Sugar.

And thus ended a Conference, the results of which will be important and far-reaching, in spite of the calamitous circumstances by which it was attended.

The Nomenclature of Garden Hybrids.

The receipt of "Addenda to Sander's List of Orchids" affords an occasion to thank Messrs. Sander for the publication of their very useful list. It is divided into three "tables," each table with three columns; in the first column the name of the hybrid is given under its appropriate genus; in the second column is inserted the name of the seed-parent, and in the third the designation of the pollen-parent is registered.

In the second table the same details are given, but differently arranged: thus, the name of the seed-parent comes first, then that of the pollen-parent, and, thirdly, that of the product.

In the third table the names of the pollen-parent are placed first, then those of the seed-parent, and in the third column the name of the resulting crossbred or hybrid. Assuming the correctness of these details, the great value of the record is obvious. The objections to be raised against it depend on the inconsistency and cumbrousness of the nomenclature; inconveniences, we must hasten to add, for which Messrs. Sander are not specially responsible, but which are mainly due to the non-observance of the rules laid down for the guidance of the committees and of raisers in general. These rules have been discussed over and over again, within our recollection, and a general agreement come to at various meetings, but those who agreed to the regulations adopted do not seem to have the courage of their convictions, or, at any rate, they fail to carry out in practice the rules they agreed to adopt in committee. The Orchid Committee in this respect sets a bad example, and does not do what it might do in regularising and reducing to system the erratic nomenclature of which complaint is justly made. Instances are so numerous and so notorious that it is not necessary to cite many of them. We take one as a sample from the list before us, premising that we are not aware whether the Orchid Committee had or had not any responsibility in this particular instance. In Table III. we find the pollen-parent of a par-

Photo by E. J. Wallis.

CHRISTMAS ROSES (*HELLEBORUS*) FLOWERING AMONGST HARDY FERNS
AT KEW.

ticular hybrid entered as *Harryano-crispum*, a hybrid to begin with! The seed-parent is registered as *Rossi rubescens*, a variety, or, preferably, perhaps, a mere variation of a species. Lastly, we come to the name given to the "product," in this case "*Smithii*." In the other tables we find *Odontoglossum Smithii* registered, of course, under the same parentage. Now, so long as the reader has Messrs. Sander's list of hybrids before him, there is no chance that anyone will be misled as to the status of *O. Smithii*. But, it is not everyone who can enjoy that privilege, or, if he possess the list, that he will have it with him for reference at all times when he has occasion to write, or still more frequently, to speak of Smith's *Odontoglossum*.

As it is, the unsuspecting botanist would naturally take a plant named *Odontoglossum Smithii* to be a distinct species, and unless he possessed Messrs. Sander's list, or some similar document, he might waste much time in the futile attempt to ascertain what *O. Smithii* was, where it came from, and where it was described. But if it had been called "*John Smith*," all this time and trouble would be saved. At the same time, if the register was properly kept he would have no difficulty in ascertaining the precise status of "*John Smith*." The importance of keeping an accurate register, always very great, has been enhanced now that so much attention is paid to questions of heredity and variation. Certainly it would be easy to act on the rule which exists already, which forbids the application of a specific name in Latin, to a plant of garden origin. As it is, the name "*Smithii*" stands on a level with "*crispum*" or "*grande*" or that of any other recognised species. Looking down the lists, we find very numerous similar cases, every one of which might have been avoided, if the rule we have mentioned had been obeyed.

Every day we hear complaints about the barbarous Latin names given to plants, but equally frequently we find gardeners and amateurs applying such names in cases where they are not only undesirable but unnecessary, and we find no attempt made by the committees of the R.H.S. to check the practice. They are ready to shout with the multitude, but not to act with the few, and until they carry their precepts into practice, so long will outsiders have reason to rail and protest.

OUR SUPPLEMENTARY ILLUSTRATION.—Do we, writes W. W., show due appreciation of *Helleborus niger* as a garden plant? Where can we find it in quantity amid surroundings that give it a chance to show what it is capable of? Here is a plant as hardy as a dock and as persistent, under ordinary conditions, as the best-tended of perennials, which comes into flower in mid-winter and continues to display its charms in spite of all weathers until the Daffodils appear. Here and there one meets with odd clumps of it either in the rock garden or herbaceous border, but they are as ineffectual as old soldiers are compared with a regiment. Last April, in a note in the *Gardeners' Chronicle* that accompanied a photographic view of Daffodils and Anemones in the Wild Garden at Kew, I mentioned the Christmas Roses which grew in a rough Fern border on the west side of this garden, and stated that 500 more plants had been added on the north-west side. The supplementary illustration to the present issue

gives some idea of the effect of these plants, near and in the distance, in January, when the photograph was taken. The brown and green fronds of the Ferns add a warmth to the combination which the reader must imagine. The display of flowers would have been finer had not many of the buds been picked off by peafowl, which are as mischievous in the garden as they are pleasing to the children and nursemaids, who delight in peacocks' tails and care nothing for Christmas Roses. The only fault that can be found with this *Helleborus* is that of impatience of transplanting; it takes at least two years to recover from the effects. The best time of year to transplant it is April, when the flowers are over and before new growth begins. The soil it prefers is a clayey loam, although I have seen splendid clumps of it in a peaty soil. The shade of trees prevents too much sun-drying, but I do not think the plants objects to positions exposed to full sunshine, provided there is plenty of moisture at the root in summer, whilst growth is being made.

THE ROYAL HORTICULTURAL SOCIETY announces, with much regret, that the Directors of the South African Products Exhibition are unable to carry out their agreement entered into with the society to clear the Royal Horticultural Hall of their exhibits for the society's fortnightly show on March 5. As the space available, therefore, is much circumscribed, the Council, whilst expressing regret for the disappointment, appeals to their Fellows and others not to send any exhibit, except those of special interest and for certificate. Fellows tickets will admit to the hall as usual. A lecture will be delivered at 8 p.m. by Prof. HENSLOW on "*The True Darwinism*." W. Wilks, Secretary.

LINNEAN SOCIETY.—At the evening meeting, to be held on Thursday, March 7, 1907, at 8 p.m., the following papers will be read:—1, Miss N. F. LAYARD, F.L.S., "*On the Development of the Frog*"; 2, Mr. S. W. KEMP, "*Biscayan Plankton Decapoda*"; 3, Prof. E. B. POULTON, F.R.S., "*A Special Point on Colour Adjustment of Chamaeleon*"; 4, Mr. G. CLARIDGE DRUCE, F.L.S., "*New Channel Island Plants*." Exhibitions: 1, Mr. H. J. GROVES, F.L.S., "*Specimens of Nitella ornithopoda*, A. Br."; 2, Prof. E. B. POULTON, F.R.S., "*Probate of the Will of RICHARD ANTHONY SALISBURY*, F.L.S."; 3, Prof. E. B. POULTON, F.R.S., "*Manuscripts of Dr. W. J. BURCHELL*, F.L.S."

HORTICULTURAL CLUB.—At the next House dinner of the club on Tuesday, March 5, 1907, at 6 p.m., at the Hotel Windsor, Sir GEORGE WATT, K.C.S.I., has kindly promised to talk about "*Himalayan Scenery and Vegetation*," illustrated with lantern slides.

NATIONAL AURICULA AND PRIMULA SOCIETY.—The thirtieth annual report of the society has been issued which shows that the association starts the year with a balance of £11 ls. 5d., and that there are now nearly 100 members. We note that the Royal Horticultural Society has decided in future to cease giving its donation of £10 to the prize fund. Perhaps the authorities are of opinion that by affording every facility to the Auricula Society they are doing as much as can fairly be expected of them.

FLOWERS IN SEASON.—Mr. BARTLETT sends a few sprays of *Pieris floribunda* to show its value as a hardy winter-flowering shrub. Its flowers commence to open towards the end of October, and usually continue until April. The unusually severe winter in Cornwall has failed to do any material injury, and even 15° of frost did no more than arrest its flowering for a short time.

CARNATIONS AT TORONTO.—One firm alone sent 8,000 blooms of Carnations to the exhibition of the American Carnation Society at Toronto, Canada, on January 23.

NATIONAL AMATEUR GARDENERS' ASSOCIATION.—A meeting will be held at Winchester House, Old Broad Street, E.C., on Tuesday, March 5, at 7 p.m., when a lecture on "*Insects injurious to the Apple*" will be delivered by Mr. FRED. V. THEOBALD, M.A.

SOUTH-EASTERN AGRICULTURAL COLLEGE, WYE.—We are informed that the Mercers' Company have made a donation of 50 guineas, and the Grocers' Company one of 10 guineas to this institution. The Indian Government Agricultural Department have appointed Mr. H. E. ANNETT, B.Sc. Agric., London, as a supernumerary chemist at the Pusa Agricultural Station. The show and conference of the National Potato Society will be held at the college on October 2, and a conference of Hop growers will also be held there during the last week in November.

LONDON DAHLIA UNION.—The hon. secretary, Mr. E. F. HAWES, informs us that the London Dahlia Union will hold its annual exhibition in the Royal Botanic Gardens, Regent's Park, on Thursday and Friday, September 12 and 18, 1907.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.—The annual meeting of this society will be held at the Royal Horticultural Hall, Vincent Square, Westminster, on Monday, March 11, at 8 p.m. Mr. CHARLES H. CURTIS, chairman of the committee, will preside. Three trustees, under the new rules, will be appointed at this meeting.

ORCHID SALES.—A glance at our advertisement columns will show that in the near future several well-known Orchidists intend to dispose of the duplicates in their collections. On March 12 Messrs. PROTHOROE & MORRIS will sell plants from the EARL OF TANKERVILLE's collection. On March 14 the same firm will hold a sale on the premises at West Point, near Manchester, of duplicates from the collection of S. GRATRIX, Esq. The "*New Hall Hey*" collection is to be sold on the premises, without reserve, on April 9 and following days, and duplicates from the "*Westfield*" collection of FRANCIS WELLESLEY, Esq., will be sold at Messrs. PROTHOROE & MORRIS' rooms in London on April 23 and 24. The "*Shirley Grange*" collection, belonging to G. H. FOLLS, Esq., will be sold at Messrs. PROTHOROE & MORRIS' rooms on March 7 and 8, and duplicates from the "*West Bank House*" collection belonging to J. LEMANN, Esq., will be sold on the premises of West Bank House, on May 7 and 8.

LINCOLN.—During the exhibition of the Royal Agricultural Show at Lincoln on June 26, and three following days, a great horticultural exhibition will also be held when handsome prizes and medals will be offered for groups of plants, collections, and cut flowers. Schedules may be had from Mr. P. BLAIR, of Trentham, Stoke-upon-Trent.

THE AMERICAN GOOSEBERRY-MILDEW.—It is said that this disease has made its appearance in several commercial plantations in some county not mentioned. If this be so, it is to be hoped that immediate steps may be taken to destroy the affected bushes by fire, and that a very vigilant watch be maintained over all plantations, and especially on newly-introduced bushes.

MR. HUNNEWELL'S PINETUM.—Prof. SARGENT has issued, in the form of an extract from the life of the late Mr. HUNNEWELL, a complete list of the Conifers for which Wellesley, Mass., is famous. Not only are the species enumerated, but details are given of the rates of growth and the dimensions of particular specimens. These details, though very interesting in themselves, are naturally more important for growers in the United States than elsewhere.

GRAFT HYBRIDS.—M. NOMBLOT has exhibited before the National Horticultural Society of France two varieties of Plums—Mirabelle tiquetée and Gloire de Louveciennes. Two branches of the last-named having been grafted on a stock of the first variety a third form appeared in the shape of a graft hybrid such as those described by Prof. DANIEL.

PROGRESS IN EARLY FORCING OF PLANTS.—So long ago as February, 1905, the florists' organ in Berlin, *Die Bindekunst*, drew attention to the users of warm water in the forcing of Lily of the Valley and to the alleged fact that its application to the crowns for one night hastened their flowering considerably. Lately the Society for the Advancement of Horticulture in the Prussian States invited an exchange of experiences in this field, and, in response thereto, Garden Inspector WEBER exhibited Lily of the Valley, the crowns of which had been soaked in warm water (35° Réaumur) (96° F.) previously to planting them, and in 14 days the plants were so far advanced as to be taken out of the forcing house. Herr SWOBODA, of the firm of J. C. SCHMIDT, Berlin, had experimented with a temperature of 15° to 20° Réaumur, and intended to carry on the experiment further. Nurseryman BEUSTER had applied water at 37° Réaumur without injury to the plants. The method has been tried at Dresden, even on Lilac, with good results, the plants being placed in tanks under water for 10 hours at a temperature of 22° to 24° Réaumur, 86° F. This method so very satisfactory, is much cheaper than etherisation, and will doubtless take its place in the early forcing of a large number of species. *Die Bindekunst*.

A HINT FOR FRUIT-GROWERS.—The Canadian and American Apples which reach our markets come properly packed, even in quality, and sent in packages of uniform size. The number of varieties sent over is small. Compare this with the higgledy-piggledy arrangements which too often prevail with us. We must not only grow good fruit—none can do it better—but we must send it to market with the same care and business methods as are adopted by our American brethren. It is of no use railing at the middleman. He, of course, likes to handle things so sent to market as to give him the minimum of trouble and the maximum of business. Our system, or want of system, too often does just the reverse.

TRADING BY STAMPED POSTCARDS.—In *Trading Made Easy*, a pamphlet, Mr. CHARLES A. HOUFE suggests that the public should be allowed to fix to the address side of a postcard stamps to the desired value in payment of an order written on the letter side, the stamps being cancelled by the sender writing his name across them, but the recipient receiving credit for the amount. One of such postcards, as in use in Germany, is now before us. A stamp for five marks (shillings) is affixed to the address side of the postcard, and the order written on the reverse side. The dealer, on presenting the card at the post-office, or, we presume, by paying it into his bank, would receive payment. Many of the difficulties attendant on the transmission of small sums would thus be obviated.

MANURING OF POTATOS.—The results of the field trials made in Lincolnshire in 1865 and 1866, under the auspices of the Midland Agricultural College, show that the most profitable application of artificials along with a small dressing of farm-yard manure is the following: 1 cwt. sulphate of ammonia, 1 cwt. superphosphate, and 1½ cwt. sulphate of potash per acre. Farmers are advised on the ground of economy to purchase their own materials and mix them for themselves.

POTATOS.—In a recent communication to the *Journal d'Agriculture*, Mr. ARTHUR SUTTON asserts with confidence that there is no Potato in commerce which can be proved to have originated from bud-variation, or sporting from the tuber, and that there is not in commerce any distinct variety of Potato which owes its origin to selection from the seed-tubers. He further states that it would be easy to take a dozen or more tubers, all of different varieties, which a jury of horticultural experts, ignorant of the origin of the tubers before them, might readily take to be the produce of one and the same variety. M. LABERGIERE maintains that by removing single "eyes" from a tuber and subjecting them to intensive cultivation, it is much more easy to obtain variations from the original tuber than if the whole tuber were planted. But during the Potato "boom" when Eldorado is said to have fetched such enormous prices, many acres in England were planted with single eyes, but no case of variation was recorded. M. LABERGIERE is also quoted as stating that Blue Commersoni is more resistant to frost than Blue Giant. To this statement Mr. SUTTON opposes the following experiment: On January 24 of this present year, as frost seemed imminent, several tubers of Solanum Commersoni were placed on the surface of the soil side by side with an equal number of tubers of Blue Giant. That night 10° of frost were registered (5.5° C.), with the result that both sets of tubers were completely frozen. The controversy between M. LABERGIERE and well-known Potato-growers in France and in this country is not only of scientific interest, but it assumes commercial importance, as the new "Violet Commersoni" is about four times dearer than Blue Giant. M. LABERGIERE brings forward a large number of statements from various observers to show that his Violet Commersoni and Blue Giant are two distinct varieties in spite of M. PHILIPPE DE VILMORIN's assertion that the two are one. One of the points brought forward in evidence of the distinctness between the two varieties is that rats show a decided preference for the Violet Commersoni. Assuming that to be the case, that does not prove that the Violet Commersoni really originated from the ordinary Commersoni. Rats and slugs we all know show great discrimination, and so do sparrows. A few years ago these pests nearly completely destroyed a patch of the White Arabis (*A. alpina*) in our garden, tugging at the stems and carrying them off. This year they have hitherto left the Arabis alone and devoted their attention to a similar patch of Vinca minor, but in this case the young healthy shoots are too tough for these marauders, and they are confining their attention to the dead shoots chiefly.

NEW GARDEN-PLANTS OF THE YEAR 1906.—With commendable promptitude the authorities at Kew have issued their list of the "new" plants described and figured in the principal horticultural periodicals for the past year. The list is arranged alphabetically, and no attempt is made to do more than register the names as they appear and to give a brief description of them. Not even the name of the author is supplied, though in some cases an indication is given of the garden whence a particular hybrid proceeded. The list is indispensable to those who desire to keep themselves informed as to new introductions.

AQUATIC WEEDS, &c.—Mr. RIDLEY, in the *Agricultural Bulletin of the Straits Settlements*, details the results of some experiments made with a view of freeing the water of the ponds from objectionable weeds, cryptogamous and other. He found that sulphate of copper was effectual in abating the nuisance, but that owing to the strength in which it must be used to secure efficiency, the water so treated is not fit for human consumption.

DISEASES OF FRUIT.—The Board of Agriculture and Fisheries has issued a further series of coloured diagrams prepared under the supervision of the Director of the Royal Botanic Gardens, Kew, to accompany the first series which deal with diseases of forest and fruit trees. The second series deals with diseases of fruit, and fruit-bearing plants. These diagrams can only be obtained at the office of the Board of Agriculture and Fisheries, 4, Whitehall Place, London. S.W. They are suitable for lecture rooms, museums, schools, etc., are contained in seven sheets, 21 inches by 15 inches, price 1s. each sheet, or 6s. 6d. a set. They will be sent post free, on receipt of the money with the order. Remittances should take the form of cheques or postal orders, and not stamps. Each diagram is accompanied by a brief account of the diseases, together with a statement of the measures to be taken for their prevention or eradication, printed in large type, in the form of a wall sheet. A small hand-book giving similar information can also be had, price one penny. The following diseases are included in the diagrams:—No. 1, Strawberry leaf-spot; Strawberry-mildew; Apple-rot; Cherry-scab. No. 2, Apple-mildew; Apple-canker; heart-wood rot; tree-wood rot. No. 3, Bladder Plums; Peach leaf-curl; shot-hole fungus; leaf blight. No. 4, Apple-scab; Pear-scab; brown rot. No. 5, Vine leaf-blotch; Vine leaf-scorch; black rot of Vine; powdery mildew of Vine. No. 6, Pear leaf cluster-cups; Apricot rust; American Gooseberry disease. No. 7, Walnut leaf-blotch; Cherry leaf-scorch; hazel mildew; silver leaf. The American Gooseberry-mildew is mentioned as likely to become troublesome in this country. Spraying with a solution of 1 ounce of liver of sulphur (= sulphide of potassium) in three gallons of water is recommended as a preventive. Spraying should be commenced just before the leaf-buds expand, and repeated at intervals, as may be necessary. It would have been advisable, we think, to have also counselled the immediate destruction by fire of bushes that are attacked. "Silver-leaf" is not confined to the Plum or Apple, but is not uncommon on the Common Laurel-Cherry and the so-called Portugal-Laurel, which are not Laurels, but species of Prunus. The use of Bordeaux mixture is so frequently advocated for various diseases that it would have been well to have published a formula for its preparation. It is astonishing how long it takes for useful information of this kind to permeate among the persons most deeply concerned. Bordeaux mixture has now been in use for many years, and almost every week we are called on to recommend its employment, but although we have often given the formula, scarcely ever do we mention it than someone writes to know what it is and how it is made. To satisfy such enquiries should they now be made, we may add that the ingredients are 6lb. of copper-sulphate, 4lb. of quick-lime, and 45 gallons of water; dissolve the copper-sulphate in 6 gallons of water in an earthen pan or some receptacle into which metal does not enter. In another receptacle slake the lime by adding water till the mixture is of the consistence of cream. Then mix the copper solution and the lime-mixture, adding the remainder of the water and keeping the whole continually stirred, as it is the sediment, rather than the liquid, which is beneficial. It is generally better to further dilute this strength by adding five or ten gallons of water before using it upon delicate foliage. In all these cases it must be remembered that prevention is better than cure. Spraying will not effect a cure, but it may, and does, prevent the occurrence and spread of fungus diseases. Weekly applications of sulphide of potassium are reported from America as having given excellent results in the case of the American Gooseberry-mildew (see Lodeman, *The Spraying of Plants*, p. 292).

E. ROSTRUP.—The death of this well-known plant pathologist at Copenhagen at the age of 76 years occurred on January 16. In 1860 he published his *Flora of Denmark*, which had a very large sale, and reached its tenth edition. At the time that he brought out this work, he was a master at a seminary for teachers, and at the same time he was studying fungi, especially those which are the cause of diseases in plants. His great knowledge in this field resulted, in 1883, in his appointment as Professor of Plant Diseases at the Agricultural High School at Copenhagen, an office that he held till his death. In his 71st year he had finished his great work on plant-diseases. He was the author of a great number of treatises, and the president of the Botanists' Club at Copenhagen.

DR. F. LUCAS, OF REUTLINGEN.—The retirement of the Director of the Pomological Institute at Reutlingen after 18 years' service, and who was likewise editor of its organ, *Die Deutsche Obstbau-Zeitung*, is announced.

LUTHER BURBANK.—An appreciative notice in the *Tribune Horticole* is accompanied by an attractive portrait. The author of the notice is Prof. STARR JORDAN, of the Leland Stamford University. The greatest credit is assigned to DARWIN, which no one will dispute. At the same time, it must be remembered that for his facts the great naturalist was very largely indebted to the horticulturists, as a mere glance at his *Animals and Plants under Domestication* suffices to show. On the materials accumulated in that work was based the *Origin of Species*, although the last-named book was the first to be published. Mr. BURBANK, who ranks as a disciple of DARWIN, seems to have done on a colossal scale what many of his predecessors did, and what they are still doing. So far as we have been able to ascertain, there is not anything novel or distinctive about Mr. BURBANK's procedures, apart from the magnitude of his operations. He has suffered severely from his friends.

FROST IN CORNWALL.—A correspondent, writing on the 23rd ult. states that another spell of wintry weather was being experienced. As low a temperature as 17° of frost was registered on the 23rd, with an easterly wind.

THE SOUTH AFRICAN PRODUCTS EXHIBITION.—This exhibition, which may be described as representative of all the South African industries, was opened by their Majesties the KING and QUEEN on the 23rd ult., in the presence of the Minister for the Colonies (the Earl of ELGIN) and a very distinguished company. His Majesty conferred the honour of a knighthood on Captain BAM, Chairman of the Exhibition Committee, whose remarks at the last Horticultural Club dinner were referred to on p. 109 of our issue for February 16. Our readers who may be able to attend the meeting of the Royal Horticultural Society on Tuesday next will have an opportunity to inspect the South African exhibits, which will so fill the hall that ordinary exhibitors are asked only to show plants or fruits which will be submitted for certificate.

BEQUESTS TO A GARDENER.—The late Lord FIELD, of Bakeham, Englefield Green, Surrey, who died on January 23, aged 93 years, and whose will has just been proved, left £500 to his gardener, THOMAS HENRY WREN. His lordship made liberal bequests to all his principal servants.

NATIONAL CHRYSANTHEMUM SOCIETY.—The fourth annual dinner of those interested in the market-shows will be held on Monday next, March 4, at Lyons' Popular Cafe, Piccadilly, W. Mr. R. BALLANTINE will preside.

SEEDING OF BEGONIA GLOIRE DE LORRAINE. After the large number of letters we have published on this subject, there can be no doubt whatever that those who wish may reproduce this popular plant by means of seed may do so. Our thanks are due to Mr. B. CROMWELL for shedding light on the matter in his weekly calendar in December last, and we are now enabled to illustrate a female flower, and a ripened capsule from material kindly sent us from the collection under Mr. CROMWELL's charge. (See fig. 64, p. 145.)

GATTON PARK ORCHIDS.—We are informed that Mr. JEREMIAH COLMAN's collection of Dendrobiums, &c., will be open to the inspection of the public on Saturday, March 2. The Gatton Park estate is near Reigate, Surrey.

COLONIAL APPOINTMENTS.—We desire to caution those seeking such appointments to be very careful to obtain information from trustworthy sources, such as the Agents-General for the several Colonies, and not to confide in any private agency without full enquiry into the status and reputation of the institution. No money should be paid in advance.

Publications Received.—*Field Experiments in Staffordshire and Shropshire*, and at the Harper Adams Agricultural College, Newport, Salop. Joint report for 1906. The committee have, for 13 years, superintended a useful work, and are now able to place the services of their Agricultural Instructor (Mr. John Rushton) at the disposal of farmers in the county.—*Midland Agricultural and Dairy College. Report on the Spraying of Potatoes to Prevent Disease*. 1906. Bordeaux mixture is recommended as being effectual and as increasing the yield.—*Circulars and Agricultural Journals of the Royal Botanic Gardens, Ceylon*. March, 1906. *Fruit Cultivation in Ceylon*. H. F. Macmillan.—April, 1906. *Bud Rot of the Coconut Palm*, T. Petch.—July. *The Spotted Locust*, E. Green.—July. *Root Disease of Hevea Brasiliensis*, T. Petch.—July. *Cotton*, C. Mee and J. C. Willis.—January, 1907. *Experiments in Blooming Wet Rubber*, J. C. Willis and M. K. Bamber.—U.S. Department of Agriculture. Bureau of Plant Industry. Bulletin No. 99. *A Quick Method for the Determination of Moisture in Grain*. By Edgar Brown and J. W. Duvel.

PLANT PORTRAITS.

PLUM, COE'S GOLDEN DROP.—*Garden*, February 16.
CAMPANULA GRANDIFLORA (Platycodon).—*Revue Horticole*, February 16.

POLYGONUM AUBERTI.—A hardy, ornamental climber from Sze Chuan, whence it was introduced to the Paris garden by P. Aubert. It is in the way of *P. baldshuanicum*, but inferior to it.—*Revue Horticole*, February 16, p. 83.

THE HORTICULTURAL SOCIETY OF VIENNA.

In a comprehensive work by Professor Dr. Alfred Burgerstein, general secretary of the society, the reader is presented with the history of the most important horticultural society in the Austrian-Hungarian Empire. The issue of the work is intended to mark the seventieth year of the society's existence, that is, from 1837 to 1907.

The society has experienced, like our own Royal Horticultural Society, a chequered existence, and has only of late years been steered into quiet waters.

In the month of May, 1827, was held the first public flower show in Vienna, and that was looked upon as an event of no small consequence, the foundation of the Vienna Horticultural Society was decided upon in consequence, the chief supporters of the idea being Carl von Hügel and several eminent horticulturists.

The flower show was held in a long glass house, standing in Prince Schwarzenburg's garden, which he lent for the occasion,

five nurserymen and 24 other exhibitors taking part in it. According to the catalogue, there were shown 589 species, varieties and hybrids, a considerable effort for that time: decorative plants in the true meaning of the word, possessing not alone of horticultural value, but of scientific interest also. Of stove plants there were 31 species; greenhouse plants, more especially natives of Australia, 112 species in 170 examples; Geraniaceæ, 96 species, and 144 examples. Contrary to present-day practice, the judges were chosen by the subscribers, who were requested to name the person he or she preferred, and the five who secured the greater number of votes were those who were chosen to act as the judges. These were Baron von Hügel, Baron von Jacquin, Hofgärtner Brede-mayer, Kustos Dr. Pohl, and Graf Harrachs, garden director at Lübeck; but, as Hügel was a competitor, Heinrich Schott was chosen in his stead. The five prizes awarded consisted of 1st, *Camellia japonica* fl. albo plena, grown as a tree, 9 feet high, which was taken by Archduke Anton, together with a *Palm Diplolothemium litoreale*, as a rare exotic. The 2nd prize, an *Astrapea Wallichii*, an example with seven side branches, was awarded for an exotic, well grown and of great beauty, to Baron Carl von Hügel, for a plant of *Erica tubiflora coccinea*, standing almost 12 feet high! The 3rd prize, for the most rare European plant, with especial regard to the Austrian flora, was awarded to a plant of *Primula longiflora*, shown by Baron von Welden. The 4th prize, another *Pæony*, but smaller, was awarded to Hon. F. J. Rolb, for *Azalea pontica*; and the 5th prize, a *Camellia japonica* fl. pleno carneo, 3 yards high, was taken by Baron Pronay, for the most beautiful Geraniaceæ, and in respect to variety with *Campylyia carinata*.

Steps were taken by Archduke Anton to bring the establishment of a society before the Kaiser, and with such good effect that Hügel was requested by Prince Metternich to draw up the fundamental plan of a horticultural society, and to take as his model the Royal Horticultural Society of London.

Although the scheme was favoured by the Kaiser, and most favourably reported on by the authorities of lower Austria, two years passed (May 20, 1830), before the government accepted the proposal to establish the society, and asked to have the statutes laid before them. Other two years had flown, and von Hügel had departed on his explorations in India and Australia, and as much importance was attached to his attendance at the foundation of the society, it was decided to wait till his return, which took place in January, 1837.

Hügel lost no time in calling together his colleagues to a conference. On January 11, 1837, with Baron Hügel as provisional president, Dr. Stephan Endlicher, secretary *pro tem.*, and Freiherr von Pereira, treasurer. The statutes were revised, and at last sanctioned by the Kaiser and his Ministers. In the revolutionary year 1848, the money troubles of the society were accentuated; many subscribers and friends failed to support it so well as formerly, or dropped out entirely, and it could barely pay its way. In 1856, things took a favourable turn, the trade sent more plants and other objects to the two or three shows held annually, and the exhibits were of better quality, more particularly in 1857, when a great number of nurserymen and florists participated, and fresh blood was infused into the management, with the object of bringing the more intelligent gardeners nearer together, Beer and Ludwig Abel called into life monthly evening meetings, which for the first time began in the winters of 1857, 1858, at which lectures were given in popular form, and rare and interesting plants were shown.

Hitherto the society had had no settled home, but in 1861 an event happened which had an important effect on the future of the society. Towards the end of 1860, the former treasurer,

Freiherr von Mayr, made a communication to the council of management that a most influential personality was inclined to make a free gift of a site for the erection of an exhibition building in the vicinity of the projected Stadt Park, and partly on the site of the old fortifications, the town ditch, and adjoining glacis; and on this spot the offices, glass houses, and exhibition saloons were erected, and a small reserve garden laid out, the entire work being finished according to agreement, within two years, reckoned from the day it was given over.

On June 2, 1870, Carl Freiherr von Hügel died. But little of what this extraordinary man did for the Vienna Horticultural Society can be related in this short sketch; but, as Dr. Burgerstein writes, page 48: "The name of Hügel will be inscribed in letters of gold in the annals

the base and on its head, leaving a white area between.

The plant, which is blooming for the first time, has four bulbs and seven blooms, and has not been disbudded, is from the same capsule as the "Rosslyn var." and is the result of crossing a blotched crispum with a fine Harryanum; the position of the blotches being indicated by the "island" spots in the hybrid. These two varieties are the finest yet bloomed from Mr. Sander's "bruggense" type of this hybrid; they are quite different in character to Mons. Vuylsteke's original cross, his being upon an unspotted crispum.

In dedicating Mr. Sander's own plant to himself, I feel sure my brother hybridists will confirm my opinion that each is worthy of the other. *De B. Crawshaw.*

habit, form of leaf, and inflorescence, and colour of the flowers. The variations appear to the visitor as if they must inevitably merge into each other. They are something like the metal lines on a giant railroad, and one cannot help picturing them running into each other just as the metals do at some great junction. We know, however, that the cultivator, whose object it is to cross and recross the varieties for the purpose of producing variation, performs another task which is of almost equal importance. This consists in keeping the strains, numerous though they are, as perfect to type as possible, and this is done by "selection." The practise of "selection" obviously implies that there is "rejection" also, and here is to be found an explanation of the non-merging of the strains. They are not united as the railway lines at a junction, because the cross-breeder, instead of fostering the connecting links, destroys them in the process of selection. He desires as many lines as are possible, but they must be distinct.

It is impossible to enjoy such a show of Primulas and to hear some of Mr. MacDonald's remarks upon the behaviour of seedlings obtained from certain crosses, without getting one's mind mixed up with questions of "genetics," heredity, Mendelism, &c. The eternal "why and wherefore" present themselves. Why has that Giant White Stellate Primula with very dark stems, crossed with a red stellate variety, produced an almost perfectly white flower with a suspicion of the "Duchess" zone in it, and having pale foliage and pale stems? When the practical man in charge of such experiments as are made at Reading declares that in the cross-breeding of Primulas Mendelism appears only perfectly true in regard to the foliage, and is not applicable to the numerous crosses that have relation to the colour in the flowers, it is clear that the science of "genetics" has not yet reached any degree of finality. At the same time, it is sufficiently evident that the science is beginning to become understandable when in one characteristic the crosses have always exactly the results Mendelism has taught the cultivator to expect. Seeds from palm-leaved or plain-leaved varieties, said Mr. McDonald, may produce the Fern-leaved type, but the Fern-leaved, after it has become fixed, has never been known to revert to the Palm-leaved form. Other interesting circumstances are found in certain varieties, which, in the matter of colour, are apparently incapable of becoming fixed. They are obtained in the ordinary work of crossing, and, being admired, the seeds are collected and sown, with the result that a number of the plants resemble the male parent, others the female parent, and some the "cross." If the process be repeated, the same result is obtained. In two instances, at least (one of which is "Giant Lavender"), it was shown us that after repeated attempts to fix these shades of colour, the varieties could not be catalogued, because it was known that seedlings from them would exhibit, in each case, the three forms already mentioned. Some would probably explain this by stating such crosses to be *pure* hybrids, and therefore unfixed, or it may be by stating that the qualities of the two parents are in such cases "mixed" (mechanically) in the hybrid, rather than "combined," and therefore remain capable of again becoming separated. It is an engrossing subject, and one upon which it is confidently expected more and more light will be shed in the immediate future.

One or two solitary plants of "stellate" crosses are very extraordinary, and although at present unattractive, they will be kept for future observation. Another solitary plant from a magenta crimson flower had flowers in which the petals were almost of the proper colour, except that a good depth of margin appeared as if it had been steeped in an acid which had removed the colour. Occasionally something similar is seen in the flowers of Dianthus. This Primula was unattractive, but it is not so much what such crosses are when they first appear, as

FIG. 61.—ODONTOGLOSSUM CRISPO-HARRYANUM "F. SANDER."

of the K.K. Gartenbau Gesellschaft, never to be obliterated." An excellent likeness of Hügel is given on p. 12.

The society conducts two horticultural schools—one the so-called Lower School in Vienna, and the Higher School at Eisgoub, a small market town in Moravia. *F. M.*

ODONTOGLOSSUM CRISPO-HARRYANUM "F. SANDER."

THE accompanying reproduction of a photograph (life-size) of this beautiful variety hardly needs any explanation save an indication of the colour.

The sepals are "marbled" with rich brown upon a creamy white ground, the petals being whiter still, with rosy lips, and "marbled" with a brown tinged by crimson, of a distinct shade to that of the sepals. The lip is white, spotted with brown, and yellow all around the crest. The column is tinted with brown both at

NURSERY NOTES.

CHINESE PRIMULAS AT READING.

MESSRS. SUTTON & SONS' vast collection of Chinese Primulas is now making a glorious display in the new glasshouses in the celebrated trial grounds near to the London Road, Reading. In many previous years we have visited the town for the same purpose as we did on Monday last, but on no such occasion was there a greater floral display to admire, or such diversity in shades of colour to interest. Perhaps there is no better manner of impressing the reader with the thoroughness of the Primula culture at Messrs. Sutton's establishment than to state that in the present season there are 270 batches of seedlings, as many as 380 different "stocks," and 14,000 plants. If these plants were arranged together on a flat surface, they would be sufficient to cover one quarter of an acre of land. In such a collection one can be easily confused with the endless variations in

what they may be capable of becoming themselves, or of giving rise to, that is taken into consideration, and even this very curious form may prove to be valuable.

We much admired a semi-giant Primula with very pale azure-blue or lavender-coloured flowers, having just the suspicion of a zone of deeper colour round the "eye." It resulted from crossing a deep purple or blue variety on to Pearl (white). The newest strain in sufficient quantity to be catalogued is known as "The Czar" (see fig. 62). It was raised from a cross between two pale blue varieties, one of which was Reading Blue. Czar has very deep purple-blue flowers, and its habit is most commendable. The plants are only seven months old, and are growing in 5-inch

the pages of which some of the best are effectively illustrated.

The semi-double varieties, including the "Duchess Double," are of a strain well worth recommendation, and the "stellate" varieties are exceedingly pretty plants for placing in a vase, whilst some of the colours are particularly effective when seen under artificial light. There are "giant" forms of each type, even of the "stellate" type, and in the "giants" there is greater vigour and substance, at the expense of profusion of flower. The "giants" are now at their best.

THE CYCLAMENS.

It would be a great omission to fail to mention the charms of the Cyclamens. The whole

PRIMULAS AT FOREST HILL.

THE Chinese Primula is commonly spoken of as the florists' Primula, and these so-called florists' flowers are among the most useful of all our decorative flowering plants, and they are specially valuable in their season of flowering. Perhaps it is from this fact, and also because they are grown in almost all gardens, that the florist has in the past devoted, and is still giving, much attention to the improvement of these excellent winter-flowering subjects. The figure in our issue for September 15 last shows a wild plant of *P. sinensis*, as collected by Dr. Henry in the very limited habitat in which it is found around Ichang, but a glimpse in the plant-houses at Messrs Carter's nursery, Forest Hill,

FIG. 62.—M^{RS}S. SUTTON'S NEW "BLUE" PRIMULA "THE CZAR."

pots, but they had produced wonderful flower "trusses," and on one such specimen we counted 35 expanded blooms. The lemon "eye" in this richly-coloured type is very effective. The foliage is Palm-leaved, and the petioles about "half-dark." The "Duchess" type and the "Duchess hybrids" are still much sought after; and a new strain of Duchess type is being collected, which in several colours possesses the characteristics of the old alba magnifica, namely, much curled foliage and flowers, and an unusual number of petals. We cannot enumerate the long list of varieties, but those interested will find them described in the firm's catalogue, in

collection is now in full flower, and it furnishes quite a marvellous display of colour.

The varieties are well known, but special reference may be made to Salmon Queen, which is almost fiery in colour. It is the brightest colour in the collection. Giant Salmon Pink, a selection from Salmon Queen, has larger flowers, but is less rich in colour. Vulcan is the deepest coloured Cyclamen, but Giant Crimson is rich in shade, and has larger flowers. Most gardeners know the merits of the beautiful white varieties "Butterfly" and "Giant White," and with mention of them we must conclude our remarks.

shows that the florist has been at work evolving something different from the wild species and more nearly approaching his own ideal. Whether he has improved upon the type in the matter of habit may be a matter of taste, but we shall all agree that he has furnished some beautiful shades of colour in the flowers of this plant. The collection at Forest Hill embraces some 10,000 plants, representative of all the best shades of colour, from pure white to the deepest purple. The ideal Primula of the florist must be neat in habit, dwarf, with its leaves in a shapely whorl, and from the centre a compact inflorescence arising, strong of stalk, and with

a well-disposed head of large flowers—the “pips,” as they are termed. Such an one is the variety King Edward, a white kind, which is grown very extensively at Forest Hill, and one whose seeds are in great demand. It may, perhaps, be mentioned in passing, that these Primulas at Forest Hill are grown especially for their seeds; consequently, they do not show excessive vigour either in plant or in flower, as robustness of growth is not favourable to the production of seed. But they were all furnished with seed pods in varying stages, and the prospect of a plentiful crop of seeds was good. The plants are all artificially pollinated, and each little batch of a certain variety has its own brush by which the stigmas are dusted with pollen. Although the varieties were staged without much space between them—only sufficient for light and air being allowed, they do not intercross. The flowers of *Primula sinensis* have a protruding stigma, and when the gamopetalous corolla drops, the stigma is brushed against the stamens as it is pulled through the corolla tube and pollen is deposited on the receptive organ. This is probably sufficient to ensure fertilisation, but no risk is taken when seed saving is the object, consequently they are all artificially pollinated, and it is an interesting fact that soon after they are dusted with the brush the corolla falls. In the raising of new varieties the selected parents are intercrossed, and should something novel be found in the

named Holborn Blue, the shade is nearer heliotrope, but it is an acquisition, and was given a First Class Certificate by the Royal Horticultural Society some time since. Lilac Queen must also be mentioned. It is a double variety, and of very free blooming habit, and the somewhat loose panicles are very highly prized as cut flowers. Indeed, all this semi-double section of Primulas are valuable for furnishing cut flowers, and perhaps nothing is more useful in its season to the florist than the old alba plena. Snowflake is very early in its season of flowering, and its semi-double flowers, when mingled with suitable foliage, are very pretty in the cut state for vases, &c. Holborn Crested is a distinct kind; the deep-rose tinted corolla has very deep fimbriations, giving it a crested appearance, and is responsible for the name. We have no space to describe all the many other varieties seen, but must mention the seedlings, and of these the most promising is a plant with beautiful coral-red petals that are very full—almost a double variety. The “pips” are very fine, and having a big truss and an excellent habit the plant will no doubt be in demand when it is placed before the public. Another promising seedling was of a beautiful magenta shade, and when properly “fixed” the colour is bound to become a favourite one. Tight and compact of habit as is the florists’ Primula, the type known as “Stellate or star” Primula is lax, and the wild parent is about intermediate between

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

BLUE HYDRANGEAS.—I have been much interested in the notes on Blue Hydrangeas, and am reminded of a very fine bank of these plants growing in a garden near Cranleigh, Surrey. The plants were growing on the banks of a dell (practically in the woods), and were all in the picture of health, and splendidly flowered. The colour of the flowers on the plants at one end was of a beautiful shade of deep pink, which, as one went along, got paler, till it was only a very delicate shade of mauve. From here they began to get more blue, till at the further end they were quite an intense blue. I enquired if anything was done to influence the colouring, the answer being “No.” The plants on which the pink-shaded flowers grew were on slightly higher ground, and in full sun, while those with the deep blue flowers were on lower ground, with rather more moisture and shade. I secured a few cuttings from the blue-flowered plants in the autumn, the resulting plants giving me some very fine flowers, but only of a deep shade of pink. I generally manage to secure a few blue-flowered Hydrangeas each season by watering the plants twice weekly with a solution of alum-water, after they begin to show their flowers. T. S., Addlestone.

SWEET PEAS.—The advice given by Mr. Brotherston on p. 90, and repeated by A. D. in last week’s issue, p. 108, to sow thinly, is not likely to be disregarded by purchasers of this year’s novelties in Sweet Peas, as many packets of these contain no more than a dozen seeds. The practice of sowing thickly is, I think, more prevalent among cottagers and small growers for market, many of whom still adhere to the old style of rows of mixed colours, and thick seed-sowing. The very fine displays from professional gardeners seen yearly at our summer shows, however, clearly prove that the advantages of thin planting have been thoroughly appreciated by them for some years. Of course, there is a wide difference between thin sowing and thin planting. In the latter case the plants are usually thoroughly hardened, and with 3 or 4 inches of wiry growth, which is practically safe from the attacks of mice, birds, or other pests. In the case of seed-sowing direct outside, the circumstances are somewhat different, and a little extra seed sown to guard against, and make good, losses from the above causes is to be recommended. It is in the neglect of timely thinning that the evil results of thick sowing become apparent, but it is difficult to make the average cottager believe that a judicious thinning is beneficial to his thick-sown rows. A second sowing about the beginning or middle of April is a great help in prolonging the flowering season of the sweetest of annuals, especially so on light, gravelly soils, or during a hot summer, the later-sown plants taking the place of the earlier batch. Unless for exhibition purposes, the sowing of three seeds in a single clump is not advisable; these, at the most, would throw no more than a dozen growths, which would make but a poor display when compared with a bold clump 3 or 4 yards through. In masses like these, planted in separate colours, in a wide border either of annuals or mixed herbaceous plants, the Sweet Pea is seen to the greatest advantage. The following is a list of varieties, with their colour:—Countess Spencer (pink), Queen Alexandra (scarlet), Navy Blue (dark blue), Lady Griseld Hamilton (pale blue), John Ingham (rose), and the Hon. Mrs. Kenyon (creamy yellow); the latter I give in preference to Dora Breadmore, which last year, with me, was frequently streaked with pink. The orange-tinted varieties (and several of these are amongst our prettiest Sweet Peas) are so liable to be scalded or scorched by the hot sun, that unless shaded during the height of the day, their true beauty is not seen. T. H. B., South Devon.

COLOCICUM AUTUMNALE.—In a foreign park under my charge this plant was a great nuisance, and as the grass was made use of as hay I had to be very careful to extract the leaves before it was mown, having lost one or two cows that were fed on it. The plants flowered capitally in the early autumn, and to rid the grass land at that season seemed to present no difficulty, but finding the corms were at least 18 inches deep in the soil I had to desist from the attempt. F. M.

FIG. 63.—NORTH-WEST AMERICAN SILVER-FIR.

To the left *Abies nobilis*; in the centre *A. magnifica* var. *xanthocarpa*; to the right *A. magnifica*; all much reduced.

batch of seedlings this seedling plant is carefully grown on and induced to seed. The seedlings of this batch will probably not all come true, and at least three years must elapse before the varieties are “fixed,” but afterwards it is remarkable how true the varieties will come from seed. In looking at a very large batch of Messrs. Carter’s Princess May, one was impressed with the great regularity in the plants, and no deviation whatever was seen in the exquisite and delicate tinting (pink) of the large petals, borne in big trusses. This is certainly a very fine variety. It is not new, but was raised at Forest Hill a few years since. Elaine is another beautiful white Primula, the “pips” being especially large and clear. The foliage is handsome and of the type known as “Palm-leaved.” The foliage differs greatly in form in some of the varieties: one was named Oak-leaf from the great resemblance of its leaves to those of the Oak; others are known as “Fern-leaved” varieties, and of this type belong the beautiful Ruby, one of most brilliant colouring, with just a speck of white at the base of the segments, and a few on the margins. Varieties, named from their colours, such as Vermilion, Carmine, Crimson, Magenta, Scarlet, &c., were noted, the colours representing very fine shades, and the plants were of excellent habit. Crimson is a variety of beautiful deep colour, and the one named Scarlet is very rich in shade.

The colours have a fairly wide range, and one approaching blue was noticed. Although it is

the two. The great value of the star Primulas for decorative purposes, and especially for intermingling amongst other subjects, has caused them to be in much favour, and very bright they appear when mingled with suitable greenery on the stages of the conservatory or greenhouse. These varieties can be had in all the choicest colours, and a very fine selection of these were noticed, labelled under their respective colours, such as Crimson, Blue, Salmon, Carmine, Pink, Purple, &c. A very large batch of plants of unnamed varieties represented a good mixed strain, with colours of most of those described.

A glance through the nursery showed a very large batch of Cinerarias that we shall probably see again at Temple Show time; also Petunias, Gloxinias, and the usual array of florists’ plants.

One house was entirely devoted to the accommodation of pigmy trees in pots that were probably more handsome than the distorted trees.

ABIES NOBILIS AND ITS ALLIES.

We are now enabled to give illustrations (on a very reduced scale) of the three species of Silver Fir to which we alluded in our last issue. To the left is *Abies nobilis* with sharply reflexed bracts, but the cone shorter and blunter than usual; in the centre *A. magnifica* var. *xanthocarpa*, alias *shastensis*, with horizontally projecting bracts; and to the right *A. magnifica* with the bracts entirely concealed. The photograph was furnished us by Mr. Crozier, of Durrus, Aberdeenshire.

ACACIAS FOR THE MARKET.—In the note on page 74 of *Gardeners' Chronicle* for February 2, concerning the importation of *Acacia* shoots in a flowering state to this country, although *A. dealbata* is named, there is no mention of *A. Decaisniana*, which is said to furnish a large proportion of the imported flowers. This plant is equally floriferous with *A. dealbata*, and has similarly globular clusters of pale yellow flowers. Perhaps it may be propagated from cuttings of the young wood, which is not true of *A. dealbata*; the latter growing only from seeds and layers. F. M.

INSECTICIDES FOR VINES.—Quite a large correspondence on insecticides has taken place recently, especially on those best fitted to destroy mealy-bug when infesting vines. It is really extraordinary how extensively this pest has invaded vineries during recent years. Yet there are several ways of destroying this insect without injuriously affecting the vines. I have tested the value of stripping the vines in as thorough a manner as possible of their bark, and have not discovered that other vines with bark intact gave any better results. Therefore on vines that are infested with bug the bark should, as a primary step, be removed. The most effective of all insecticides is undoubtedly hydrocyanic acid gas, and vineries cyanidised before the buds have made much progress remain clean practically through the summer. But much lack of knowledge regarding the use of hydrocyanic acid gas still prevails, and I have recently seen as much as 6 oz. of cyanide of potassium per 1,000 cubic feet recommended, and the fumes to be confined several hours. In my experience, if 4 oz. per 1,000 feet are used longer than half an hour, it is dangerous to vegetation. With regard to tar, I have tested it on vines when in a resting state and on others in full growth. In the latter state it may be used neat. The usual formula, which I think is that recommended by Mr. H. W. Ward, of nine parts of clay to one of tar, is safe, but ineffective, unless the vines have been thoroughly cleaned previously. Tar and water do not readily mingle, therefore I, first of all, mix the tar with the dry powdered clay and then add warm water to bring the material to the consistency required. Of petroleum it may be said that it varies so much in quality that one is never sure of it. I never use it on vines, for no matter how carefully it is emulsified, it acts injuriously, though the vines grow out of check in the course of the season. There is yet another insecticide which I have often applied and always effectively, but as it is liquid it is not so searching as hydrocyanic acid gas. This is hot water, the degree of heat being to a large extent governed by the operator, who prefers it to be less hot than vines will bear it in consideration of his hands. By the simple means of syringing vine rods occasionally up to the breaking stage, no bug or other insect is left alive to attack the early leaf, and if ants are not colonised in vineries, none will appear later. The advice I gave to a gardener who applied for something to cleanse infested bunches I may also give here. It was simply to syringe vines and bunches repeatedly with hot water, letting the water run down the latter rather than forcing it among the berries, which, moreover, will not stand it so hot as will the foliage. If the water employed is soft and pure, the bunches are practically not damaged at all, and though it might be expected that the dirt made by the bugs would spread over the berries, even that is washed away, with the exception of a little sediment left on the point of a few berries. R. P. Brotherton.

GAS TAR AS AN INSECTICIDE.—I am pleased to note that one correspondent, T. A., has proved that gas tar used in its pure state did no mischief when applied to young trees. A farmer planted some 60 pyramid Apple trees last autumn, under my supervision, and during the winter hares attacked the bark. Some friend of the farmer advised the painting of the trees with tar, which was done before the matter was mentioned to me. I have made enquiries, and have been told by one who has proved it, that tar causes the trees to remain dormant, and to make no growth for three or four years, after which time they cast off the bark where the tar was applied, and grow away fairly satisfactory. I shall be glad if any reader will furnish me with instructions for removing the tar from the trees which is on both the stem and the lower branches. T. J. H.

BEGONIA GLOIRE DE LORRAINE.—I have about 170 plants which have been used for decorative purposes since November 1, and most of them have been in the dwelling-house on several occasions. A good many seed pods are forming, and I counted 16 on one plant in a 4-inch pot. Most of the plants in 4-inch pots have seed pods forming, but there are very few on those plants in pots of larger sizes. The Turnford Hall variety is also forming seed pods in 4-inch pots. H. Chaplin, Normanton Gardens, Stamford.

I have examined a small batch of these plants in these gardens and I found 126 seed capsules on 24 plants. All are terminal flowers. Unlike Mr. Cromwell I have found a few male flowers with five petals, and one female flower with

FIG. 64.—BEGONIA GLOIRE DE LORRAINE, SHOWING ONE TERMINAL FEMALE FLOWER WITH OVARY AND ONE LATERAL MALE BLOOM.

six petals, but most of the males have four and the females five. We grow the plants in a small house where Melons are cultivated in the summer time. At present the house is kept fairly warm and dry. Fred. Low, St. Clare Gardens, Sevenoaks, Kent.

I agree with Mr. Cromwell, page 94, that *Begonia Gloire de Lorraine* produces its female flowers freely. But as I have never sown any seed I cannot testify as to its germination. Some years ago when the same subject was discussed in the *Gardeners' Chronicle* I had ripe seed, and (like W. B., page 94) lost all interest in the matter when it was said that they would not reproduce themselves from seed. I do not agree with W. B. entirely as to the scarcity of female flowers, as I think that if the plants are kept

FIG. 65.—SEED POD OF GLOIRE DE LORRAINE BEGONIA, SHOWING THE THREE WINGS AND THE STYLES.

To the right a section across the capsule.
(From Mr. Cromwell.)

healthy and without check they will produce female flowers quite freely. In the majority of cases the plants are cut back before they produce the female flower. R. Mountford, Norton Priory Gardens, Runcorn.

I have now upwards of 460 seed capsules of this *Begonia*, and since my notes, published in these pages on January 19, I have counted on the dwarf pink variety 860 fruits, in addition to those the seeds of which I have already sown. Of these 86 have now ripened. The large flowering variety, with the exception of four or five plants, will be some time before they show their terminal flowers. I find this variety is the best to withstand the fogs which, as a rule, are very bad in the Thames Valley. I have a small batch of this variety coming into flower, on which are some very fine blooms, some measuring over 1½

inch in diameter. R. Goodbourn, Ankerwyche Gardens, Wraysbury, Bucks.

I have been interested in the differences related by the various growers of this plant, but I fail to see why growers should be surprised to find this, or, indeed, any other plant, grow more vigorous from seeds than from cuttings. Nature does not usually increase plants from cuttings, and I could never see any reason why this *Begonia* should not produce fertile seeds. When a hybrid is raised from two plants of the same genera why should not the offspring seed? Reference has been made to that observing hybridist, the late Mr. James Martin. Only a few days before he died he made reference to *Begonia Gloire de Lorraine*, and suggested that it would be a shy seeder, which inference has proved correct. Some 25 years ago a hybrid *Begonia*, having the name of Fanny Giron, was placed on the market. This was a poor grower, but very floriferous, and a most attractive kind. With me it would not seed. I noticed it produced male flowers first, and from the abundance of bloom I was under the impression the non-seeding arose from exhaustion. Speaking in a general way gardeners are not much concerned with the seeding of plants, and this may often lead them to come to many inaccurate conclusions. Mr. Cromwell makes reference to the differences in the shape of the male and the female bloom, and in their size. This also applies to other *Begonias*. For years I have grown this *Begonia* under much colder conditions than is usual, and to obtain plants of large size I place three cuttings in one pot from the first, by which system I find them more enduring for furnishing, and the flowers are of a deeper colour. John Crook, Fords Abbey.

QUICKLIME FOR CURRANT BUD MITE.—There is no ingredient more often recommended for destroying insects, &c., than the above, generally (e.g., in Mr. W. Collinge's recipe for destroying the Black Currant Mite) in a finely-powdered condition. Yet, considering the rapidity with which it absorbs moisture from the atmosphere, I venture to doubt whether, in 99 cases out of 100, it really is "quick" and not "slack" lime. As the former is, I find, very difficult to procure (indeed I do not know where to get it), and the latter very easy, it would be well to know whether this would not do as well. Of course it will not have the caustic quality of *real* quicklime. Perhaps one of your chemical readers will enlighten us. [If slaked lime is used, it is important that freshly slaked material be obtained.—ED.]

MUSA BASJOO.—Does this species bear edible fruits, or are its fruits, like those of *Musa ensete*, small and hard? Six years ago a large two-stemmed plant, which was grown in a tub for sub-tropical work in the gardens here, showed signs of flowering, and, as it was then nearly the end of October, I had it moved into a house in which a night temperature of from 60° to 65° Fahr. was maintained to ensure its flowering. At this stage the stalk was just over 6 feet in height. As the flowers opened they diffused a pleasing perfume suggestive of Roses and newly-mown Hay. We had great hopes of a crop of fruits, but although the flowers dropped and the "fingers" showed signs of swelling, they did not become more than 1½ inches long, and after a few weeks shrivelled slightly and turned yellow, and when opened did not yield any seed. Another plant has passed seven winters in the open ground without the slightest protection, and as many as 15° of frost have failed to do it any harm, so that the species may be considered to be practically hardy. When grown unprotected in the open it becomes to all intent and purposes a herbaceous perennial; the small true stem at the base of the bundle of overlapping leaf-stalks which constitute the apparent stem answers the same purpose as the fleshy root-stock of many perennials, and fresh leaves are thrown up from the same stem year after year. Four or five degrees of frost usually blackens the leaves of this Banana, and more severe cold kills a part of the false stem. During an average winter the top half of this leafy stem is killed, and the recent severe frosts have cut them down to within 9 inches of the ground, but an examination shows that below this point the plants are uninjured. In the spring these plants push up fresh leaves, and by midsummer they are well furnished with luxuriant leaves. Being gross feeders I give them an annual top-dressing of cow-manure. A. C. Bartlett, Pencarrow Gardens, Cornwall.

PLANT NOMENCLATURE.—Neither the Vienna Congress nor any other congregation of botanists will ever convince practical people that a very large number of the botanical names now given to plants are not absurd, as absurd as the names that certain people delight in giving their children. All efforts to make the name describe or tell the origin or the distribution of a plant are not only futile, but the result is often misleading. There are dozens of instances, as every gardener knows. Does anyone believe that such names as *Zygopetalum* or *Paphiopedilum* fit the plants in some special way? Of course, we must have names for plants, but just as John Smith is a simpler name than Algernon Cholmondeley, so would much simpler and more euphonious names be better than all such as those mentioned. The poor plant sometimes suffers from the ugliness of its name. I know people who will not grow *Eschscholtzia* because their name is so ugly. And some of us steer clear of such names as *Phragmopedilum* for the same reason. The ugliest thing that has been done lately has been the institution of the jumble name for multi-generic hybrid Orchids. It is a sort of Bakerloo mixture, on the principle of calling a cup of tea a cup of watermilksgartea, so that we can know the whole concoction by its name. Thus we have *Brassocattleya*, *Brassocattælia*, and, before long, we shall have *Brassocattælepiphrontis*. Surely this is ridiculous. It never should have been started. When two so-called genera interbreed that is a proof of their congeneric relationship, and one name should go, at any rate so far as the hybrid is concerned, which should be named after its mother, the father being often conjectural. Is it too late to set this matter right? Now that the breeder has got a grip of the breeding art he will go ahead, and botanists will be forced to pay attention to the results of his work. If he shows that the botanist made a bad shot when he separated certain plants into different genera the botanist had better admit it. Unfortunately he is too often obstinate, and will continue to give to mongrels such absurd names, whilst we continue to make gardening look ridiculous by accepting them. *W. Watson*. [Mr. Watson should be thankful he is not a chemist. In any case the worst offenders are not the botanists, but the growers.—ED.]

THE POISONS BILL.—The new Poisons Bill was re-introduced into the House of Commons and read a first time on the 22nd ult. Clause 2 of this Bill is to make it legal for the horticultural and agricultural trades to retail poisonous preparations required in these industries. The new regulations proposed in Clause 2 practically contain the amendment of the law for which the "Traders in Poisons Society" have been agitating for the past four years. It is fully anticipated that the Government will push this Bill to a second reading at a very early date, and that Clause 2 will pass as it now stands. The new Poisons Bill has already passed the House of Lords, and when the Special Commission sat to enquire into the present law regulating the sale of poisons, a majority report was given by his Majesty's Privy Council in favour of the present Bill, and it is well known that it is strongly advocated as a necessity by the Board of Agriculture, so that there is very little doubt about it passing. *G. H. Richards*.

BIRD LIFE IN LONDON.—To those persons who visit London only occasionally, the large and representative collection of the feathered world in the parks has caused surprise. Rare kinds are not seen in the heart of the city, but a fair number of uncommon ones are met with in the outlying parks, such as at Waterlow Park. Here, on several occasions, the Kingfisher has been seen, Bullfinches and Greenfinches are not uncommon, whilst the Missel Thrush, Blackcap, Bluetit, the busy little Wren and the Redwing are met with. The Woodpecker flitting from tree to tree, in search of the destructive goat moth, and the Owl, with its nocturnal cries, both find a home here. The Chaffinch is not often seen. One of the greatest boons legislators could bestow on persons having the care of gardens would be to place a small tax on cats. Residents of towns can have but a faint idea of the wholesale destruction of our feathered friends by their feline companions. Starlings are generally too quick for pussy, but Blackbirds and Thrushes fall an easy prey to the large army of cats. *A. J. Hartless*.

SOCIETIES.

THE AMERICAN CARNATION.

JANUARY 23.—This society held its 16th annual meeting and exhibition at Toronto, Canada, on the above date. In spite of a temperature of 8° below zero, and the consequent delay of trains, the exhibition was a success and, according to the American papers, there was an attendance of at least 300 Carnation specialists. Much was made of the fact that the meeting was held on Canadian soil and of the consequent opportunity for cordial fraternisation between the two sections of the Anglo-Saxon race. Among the communications was one by Mr. Engelmann, of Saffron Walden from which we take the following extract:—

"The American Carnation stands in England to-day something like this: There are, I should say, about 1,000,000 plants grown for the production of cut flowers alone. Ninety per cent. of these at least are cultivated in pots. Of the remainder, two-thirds are planted on raised benches and one-third on solid beds. The latter two methods are gaining in favour, and in ten years' time I should not be surprised to see the state of things reversed. Besides these, there is a large quantity grown in private establishments, and hardly any of the up-to-date estates is now without its special Carnation house.

"The number of the American kinds grown in this way I should estimate at 100,000 to 200,000. Ninety-five per cent. at least are grown in pots. This number is constantly increasing, and there is no doubt that the modern winter flowering Carnation is beginning a fight for supremacy with the *Chrysanthemum*, which has hitherto been the unassailed queen of the autumn and winter. I calculate that in five years' time there will be at least three times the present quantity grown in England."

Mr. Engelmann says the sun does not shine at all in London throughout November, December, and January, at least not to any appreciable extent. The qualification is needed, for the registers for the last few months tell a very different tale; though, no doubt, we are far in arrear of some of the States in the matter of sunshine. We fancy if the American grower were subjected to the same disabilities that we are, that he would turn on the electric light or avail himself of acetylene, but we on this side of the Atlantic are slow to adopt new methods. At the same meeting Mr. Dutton, who was the first to introduce the American Carnation here, describes Britannia as the finest scarlet, and he notes the fact that many of the varieties which do well in America prove very poor here. Enchantress still maintains its reputation, and is held up as a model to be "lived up to."

SOUTHAMPTON ROYAL HORTICULTURAL.

FEBRUARY 4.—The annual general meeting of this society was held at the Municipal Offices, Southampton, on the above date. The Mayor, Alderman R. Andrews, J.P., presided over a large attendance of the members. The statement of accounts showed an adverse balance on the year's working; the total receipts, including £50 from the reserve fund, amounted to £702 10s. 11d., and the expenses, including debts from the previous year, to £702 18s. 11d. The Chairman, in moving the adoption of the report, said the exceptionally severe weather on the occasions of the last two autumn shows had reduced their cash balance, but their receipts from subscriptions are increasing, and their exhibitions are improving in quality. The report was unanimously adopted. All the retiring officers and members of the Council were re-elected, including Sir Samuel Montagu, Bart. (president), Mr. H. J. Blakeway (chairman of the Council), and Mr. C. S. Fudge (secretary, for the thirty-fifth time).

CARDIFF AND DISTRICT CHRYSANTHEMUM.

FEBRUARY 7.—The annual general meeting of the above society was held, under the presidency of Mr. John Grimes, chairman, on the above date. There was a large attendance of members. The statement of accounts showed the total receipts for the past year was £304 13s. 6d., and the expenditure £322 12s. 4d.,

leaving an adverse balance of £17 18s. 10d. Mr. Boon, one of the hon. auditors, pointed out that the deficiency in the receipts was due to the inclement weather on both days of the show—there being a falling off of £42 on the takings compared with those of the preceding year. The balance sheet was duly adopted. The chairman, in reading the committee's report, dealt fully with the items, and said that with rigid economy the expenditure had been reduced by £18, and he was pleased to say that amounts had already been promised which would cover the deficiency. The three challenge cups had been won finally, and the committee were endeavouring to replace them.

Mr. J. W. Courtis, J.P., president, and the other officers were re-elected. The dates of the show for 1907 were fixed for November 6th and 7th. *H. G., Hon. Secretary.*

ROYAL METEOROLOGICAL.

FEBRUARY 20.—The monthly meeting of this society was held on the above date at the Institution of Civil Engineers, Great George Street, Westminster, Dr. H. R. Mill, president, in the chair.

Mr. Edward Mawley presented his report on the phenological observations made during 1906 by observers in various parts of the British Isles. The most noteworthy features of the weather of the phenological year ending November, 1906, as affecting vegetation, were the dry period lasting from the beginning of June until the end of September, and the great heat and dryness of the air during the last few days in August and the first few days in September. Wild plants came into flower in advance of their usual dates until about the middle of April, after which time they were, as a rule, to about the same extent late. Such early spring immigrants as the swallow, cuckoo and nightingale reached these islands somewhat behind their average dates. The only deficient farm crop, taking the country as a whole, was that of Hay, all the others being more or less over average. The yield of Apples was about average in all but the north of England and in Scotland, where there was a very scanty crop. Pears and Plums were everywhere very deficient, whereas all the small fruits yielded moderately well. As regards the farm crops, the past year proved even a more bountiful one than that of 1905.

THE BRITISH GARDENERS' ASSOCIATION.

MEETING AT KINGSTON.

FEBRUARY 22.—A meeting of the association promoted by the Richmond and District Branch was held in the Fife Hall, Kingston-on-Thames, on the above date. Judging by the attendance (97 or 98 persons), the gardeners in the district are fully alive to the fact that their profession is in need of such an association to look after its interests. The meeting was presided over by Mr. Alexander Dean. An address on the aims and objects of the B.G.A., given by Mr. R. Hooper Pearson, occupied a little over one hour. The chief points touched on were that co-operation amongst gardeners would benefit the employer as well as the gardener and keep out of the profession untrained and inexperienced men. Reasonable rates of pay and hours of labour were legitimate objects for which to strive. Certain bothies in the British Isles were unfit for their purpose, and, as recently stated by the *Estate Magazine*, were they in any other place they would long ago have been condemned as unfit for human habitation. He (Mr. Pearson) instanced two cases of death due to unhealthy bothies, which had come under his own notice. The B.G.A. should encourage gardeners to rise in their profession, and assist them when out of a situation to obtain another, and help employers to obtain men with the experience and ability necessary to carry out the duties of the position to be filled. Good employers had nothing to fear, but much to gain, from the association. When the association was first started, many predicted failure, but the membership is now over 1,000, and the Society has a balance of £250 in the bank. He (Mr. Pearson) thought this did not look much like failure. It was hoped shortly to commence the publication of a B.G.A. Journal, which would help to keep the members in closer touch with each other. Messrs. Hussey, J. Weathers, W. Watson, and

others subsequently discussed various points arising out of the address. Judging from one question asked, namely, whether nursery "hands" were eligible for membership, much work has yet to be done before the gardeners of the country become fully conversant with the aims and objects of the association. Mr. Pearson and Mr. Weathers both made some remarks on this subject, saying that in whatever branch of horticulture a man was employed, provided he had the necessary experience and qualifications, he was eligible to become a member of the association. Those employed by nurserymen, seedsmen, public bodies, &c., were as eligible as the gardeners employed in private establishments.

Mr. Alex. Dean, at the close, said after what they had heard that evening, he thought all those not already members (especially the younger men) should seriously consider whether it would not be to their advantage to join the association. He expressed his intention of becoming a member, and pointed out that an old man like himself was scarcely likely to lead younger men astray. Others present expressed their intention of joining, and applied for forms of membership before leaving the room. During the evening the General Secretary remarked that the Sunderland Branch was one of the strongest in the country. In the Richmond and District Branch it has a healthy rival. A. O. (Branch Secretary).

NATIONAL CHRYSANTHEMUM.

FEBRUARY 25.—The executive committee of this society held a meeting at Carr's Restaurant, Strand, Mr. Thomas Bevan presiding.

The Forest Hill Chrysanthemum Society was admitted to affiliation.

The secretary presented an interim statement of receipts and payments to date, showing a small balance in hand.

The report of the schedule sub-committee next occupied the attention of the meeting and involved much discussion and consideration. The report mentioned that the available sum to be offered in prize money could not be computed at more than £306 15s. 6d.; special prizes in addition. Two prizes for the October show, six for the November, and two for the December were recommended, and it was further proposed that a small sub-committee be appointed to arrange the spacing and setting out of the shows with a view to increasing the general artistic effect.

Mr. C. H. Curtis announced that the printers would have the new year book ready for distribution in a few days. Several new members were elected.

DEBATING SOCIETIES.

BRIGHTON AND SUSSEX HORTICULTURAL.—A lecture on "Cucumbers and Tomatoes" was given by Mr. M. Elliott, of Hassocks, at the first meeting of the year, in connection with this society. Mr. G. Miles, chairman of the committee, presided, and there was a large attendance. Dealing with the "spot disease" of Cucumbers, he recommended a mixture of carbolic acid and water in the proportion of a table-spoon to two gallons of water. It was important not to put the liquid on the plants or the soil in which they were growing. It should be used about the greenhouse, on the floor and the walls. In answer to a question, Mr. Elliott recommended the fumes of burning cayenne pepper and spraying with a weak solution of soft soap as a remedy for red spiders and other parasites; but cautioned growers to avoid inhaling the fumes of the pepper.

CRAWLEY AND DISTRICT GARDENERS.—Mr. Joseph Cheal presided over the annual meeting of this association, held on Tuesday, February 19. The total receipts for the past year were £38 16s. 9d., and of this a credit balance remains of £8 0s. 4d. Six new patrons and nine members were enrolled. The report, which was read by the hon. secretary, shows a prosperous state of affairs, and is a general record of the year's work.

REPHILL, REIGATE, AND DISTRICT GARDENERS.—The usual fortnightly meeting of this association was held on Thursday, February 21. Mr. F. C. Legge occupied the chair. Mr. G. Duncan, Mertham House Gardens, read a paper on "The Cultivation of Grapes." A clear open space should be selected for the site of a vineyard, which should be a span-roofed structure for preference. Mr. Duncan explained the methods of making a vine border, and gave details of the compost best suited to vines. Methods of planting and the subsequent treatment of the young vines were touched upon, also such questions as thinning, ventilation, watering, stopping and tying. A good discussion followed. F. C. L.

BECKENHAM HORTICULTURAL.—"Cyclamen" was the subject of a paper read by Mr. T. Cresswell to the members of the above society on Friday, February 22. It was an excellent paper, full of useful information on such subjects as seedling, seed sowing, the best soil, potting, syringing, watering, &c. On the table were four beautiful specimens of these plants, exhibited by the lecturer.

MARKETS.

COVENT GARDEN, February 27.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—ED.]

Cut Flowers, &c.: Average Wholesale Prices.

REMARKS.—Valencia Oranges now arriving are of very poor quality, consequently this has caused a greater demand for those from California and Jamaica. Madeira Beans were a short supply this week, and samples have realised high prices. E. H. R., Covent Garden, Wednesday, February 27, 1907.

POTATOES.

Bedfords, 65s. to 80s.; Blacklands, 65s. to 75s.; Lincolns, 70s. to 95s.; Yorks, 80s. to 100s.; Dunbars, 90s. to 120s.; Teneriffe, 10s. to 12s. cwt. Trade has been bad during the past week, and stocks have largely increased. Firm prices are, however, maintained. W. J. C. & S., Covent Garden, February 27, 1907.

COVENT GARDEN FLOWER MARKET.

Trade is very quiet and supplies are over plentiful, with the exception of really good Ferns, supplies of which are a little short, the spring-grown plants being later than usual, while the autumn stock is exhausted. Cyrtomiums are the most plentiful amongst Ferns, and just at this season the old form is better than the variety Fensoni and others with broad pinnules. Asplenium biforme is fairly good both in 48 and 32 size pots. Many of the specimens of Aralia Sieboldi seen are very "soft." Araucaria excelsa is cheaper. Aspidistras are also lower in prices. Palms vary but little; they are well supplied in all sizes. Among flowering plants Cinerarias are now plentiful, and their prices have fallen considerably. The best samples of Genistas do not realise more than 10s. per dozen. Erica Wilmoreana and the white variety are much better in quality than usual, the late autumn being favourable for the formation of their blooms. E. persoluta alba is also very good. Indian Azaleas are over plentiful. Narcissus, Hyacinths and Tulips are all much cheaper. Acacia ovata and A. Drummondii, also Boronia megastigma, are now seen. Primulas to be had include Primula sinensis and P. obconica. Marguerites are plentiful and good. Solanums are almost over for the season.

CUT FLOWERS.

Daffodils are the leading feature among cut flowers: their prices have fallen considerably during the past week. We now see many of the better sorts, such as Emperor, Horsfieldi, Henry Irving, Sir Watkin, Stella, and others. Some of the finest Lily of the Valley I have ever seen was on view this morning, but prices for this flower have dropped. Of Callas it is difficult to state prices; the best fresh blooms are in demand, but I have seen samples sold at from 2s. to 2s. 6d. per dozen. Lillium longiflorum still realises favourable prices. L. lancifolium is more abundant and consequently cheaper. English Violets sell fairly well. Among Roses some of the best blooms of Richmond have made 12s. to 15s. per dozen, but good blooms of General Jacqueminot are realising from 4s. to 6s. per dozen only. It is very difficult to give even approximate prices for Roses. Many of the small blooms are disposed of for very poor returns, even if sold at all. Carnations also vary very considerably: many of the blooms are not of the best quality. Gardenias are still very scarce. Camellias are sold for almost any sum. Extra special quality Tulips keep up remunerative prices. Good Asparagus is not abundant, but other kinds of foliage are well supplied. A. H., Covent Garden, Wednesday, February 27, 1907.

THE WEATHER.

THE WEATHER IN WEST HERTS.

Week ending February 27.

Rapid changes in temperature. After four cold days there came a change to warmer weather. On the two coldest nights the exposed thermometer registered respectively 18 and 15 degrees of frost. The ground temperatures have varied greatly during the week. On the first day the reading at 1 foot deep was 40°, four days later 35°, and at the present time 40°, which is slightly warmer than is seasonable. At 2 feet deep the changes were, of course, not quite as marked. Rain, snow, or hail fell on three days, but to the total depth of less than a tenth of an inch. The soil has now become drier. In fact, on each of the last two days only a few drops have trickled through either of the percolation gauges. The sun shone on an average for 4½ hours a day, or for 1½ hour a day longer than is usual at this season. On the sunniest day the sun was shining brightly for 7 hours 20 minutes, an unusually good record for February. On the other hand, on two consecutive days the sun shone for less than an hour. The first day of the week was very windy, but since then calms and light winds have prevailed. On the 20th the average velocity of the wind between 10 a.m. and 7 p.m. was 24 miles an hour, and in the windiest hour 26 miles was recorded—direction W.N.W. The mean amount of moisture in the air at 8 o'clock in the afternoon fell short of a seasonable quantity for that hour by 3 per cent. A selected bush of the Wild Hazel first showed a fertile flower on the 26th inst., which is eight days later than its average date in the previous 16 years, and 11 days later than last year. E. M., Berkhamsted, February 27, 1907.

SCHEDULES RECEIVED.

HAWICK HORTICULTURAL SOCIETY'S annual summer show to be held in the Exchange Halls, on Saturday, August 31.

ROYAL CALEDONIAN HORTICULTURAL SOCIETY'S spring show, to be held on Wednesday and Thursday, May 8 and 9, and autumn show, to be held on Wednesday and Thursday, September 11 and 12, 1907. Secretary, P. Murray Thomson, Esq., 5, York Place, Edinburgh.

Obituary.

JOHN VICKERY.—This Gardener died on the 20th ult., at the age of 67 years. Deceased had been Gardener for the past 19 years to Miss Keen, of The Cedars, Streatham Hill, and was previously Gardener at Wood End, Chichester, Sussex, Oakdene, Holmwood, Surrey, and Porter's Park, Shenley, Herts.

ENQUIRIES AND REPLIES.

PRIMULAS.—In answer to S. G., I may state that I have grown a batch of *Primula stellata* as two-years-old plants this season, with greater success than I at first anticipated. They were grown in 5-inch pots in the first year, and last June they were repotted into 7-inch pots, shaking off the loose soil and repotting in the usual compost. From that time, until the end of October, they remained in a span frame, stood on ashes. Since then they have been in a span-roofed house, in which the temperature at night was kept at about 50°. During the summer they were only shaded, when found to be suffering from bright sunshine, and apart from having occasional dressings of artificial manure, they were given very little attention. The plants are now in full bloom, and as good as could be wished for. I should advise anyone wishing for good plants of *Primula stellata* to grow them for two years. J. Hoare, Grenehurst Park Gardens.

The successful cultivation of Primulas as two-years-old plants is a simple process, especially with those of the "stellata" strain. The ordinary

Primula sinensis is less hardy and more susceptible to the effect of damp. Early in April dismantle the one-year-old plants of all flowers and flower stems, scrape a little of the old surface soil away, and if necessary remove a few of the bottom leaves, so as to leave a clear stem an inch or more in length. Mix some clean moss and silver sand, and pack this compost firmly round the stem, filling the vacant space on the top of the soil as far up as the base of the growing leaves. Place the plants on a bottom of coal ashes in a frame, near the glass, and keep the frame closed for a time. Keep the moss damp, and shade the plants from strong sunshine. When the plants have rooted into the moss, cut the stems through at the level of the old soil in the pots, pot them into as small pots as possible at first, then pot on in the usual way. These plants will be found much superior to seedlings. Plants grown from seeds sown in June, and wintered in 3½-inch pots, if potted on carefully in the following spring, will also make good plants for flowering in the following winter. W. M. M.

ANSWERS TO CORRESPONDENTS.

* * * The Editor will be glad to receive, for consideration, large photographs of horticultural subjects, suitable for forming Supplementary Illustrations to this Journal.

BIRD-LIME: *Vitis*. This substance is usually made by boiling the inner bark of the Holly until it is of sufficient viscosity. On page 138 in our issue for March 3, 1906, is described a method of making a bird-lime from linseed-oil. Put the oil into a can, place the tin in a saucepan of water, and let it boil slowly till it is of the required thickness or stickiness.

CALCEOLARIAS FAILING: *Subscriber*. Without seeing the plants, we can only attribute the injury to frost. Examine the plants to see if they are properly rooted, or whether wire-worm has eaten them below the ground.

CARNATION SHOOTS: *Correspondent*. These are attacked by the "Carnation fly," a dipterous insect resembling the common house fly, but smaller. Your only course is to remove the infected shoots and burn them, and the only means of preventing the insects laying their eggs is to dust the shoots, when moist, with dalmation powder soon after layering. R. N.

CUTTING AND RELAYING TURVES: *One who wishes to know*. Assuming your acre of pasture land to be square, the line will have to be stretched 171 times one way at 14 inches apart, and the same number of times the other way (crosswise) at the same distance from line to line, cutting into the grass about 2 inches deep with an edging iron, two men being engaged in doing the work, starting from opposite ends as they shift the line. This will give 37,337 turves 14 inches square, or thereabouts, when cut evenly, between 1 and 2 inches deep, with the turfing iron. We think a fair price for cutting the turves, carting them 200 yards and relaying them temporarily, would be £12. And in this sum allowance is made for the nature and character of the turf to be cut, inasmuch as some grassy surfaces have very fibry and wiry roots, and are, therefore, much harder to cut than are turves of an opposite character.

FISH HATCHERY: *Fisher*. During recent years a number of books have been written upon this subject, many of which can be had for a few shillings. "The History of Howietoun," by Sir R. Maitland, published at 21s., by T. and A. Constable, Edinburgh, and "An Angler's Paradise," by J. J. Armistead, published at 12s. 6d. by *The Angler*, Scarborough, are two of the best, and you will be able to find all the information you require in either. See also an article on this subject to be published in an early issue.

INSECT IN VINERY: *Vitis*. The specimen you send is one of the weevils. Trap them with slices of such vegetables as Carrots and Potatoes. They commit their depredations mostly at night time, when they should be hunted with the aid of a lantern. See the *Calendar of Garden Operations*, p. 129.

IRIS: *F. C. P.* The Iris corms have not, in any way, been injured by insects. The small grubs present in one of the decayed specimens have nothing whatever to do with the origin of

disease. I find on examination that the rotten corms are filled with the mycelium of a fungus, but this is apparently *post hoc*, as I failed to find any trace of a fungus in either the partly decayed corms or the leaves. My own interpretation is that the disease is possibly due to bacteria. R. N.

MUSHROOM BED: *W. R.* You should make a fresh bed and insert spawn as last year. Obtain *Mushrooms and How to Grow Them*, by Jno. F. Barter, price 1s. 2d., post free.

NAMES OF FLOWERS, FRUITS AND PLANTS.—We are anxious to oblige correspondents as far as we consistently can, but they must bear in mind that it is no part of our duty to our subscribers to name either flowers or fruits. Such work entails considerable outlay, both of time and money, and cannot be allowed to disorganise the preparations for the weekly issue, or to encroach upon time required for the conduct of the paper. Correspondents should never send more than six plants or fruits at one time: they should be very careful to pack and label them properly, to give every information as to the county the fruits are grown in, and to send ripe, or nearly ripe, specimens which show the character of the variety. By neglecting these precautions correspondents add greatly to our labour, and run the risk of delay and incorrect determinations. *Correspondents not answered in one issue are requested to be so good as to consult the following numbers.* **FRUITS:** *Cantreyn*. 1, Reinette de Breda; 2, Hanwell Souring; 3, Maltster; 4, Norfolk Bearer.—*W. M.* 1, Court of Wick; 2, Norfolk Stone Pippin; 3, Duchess' Favourite; 4, Lodge-more Nonpareil; 5, Not recognised; 6, Blenheim Pippin.

PLANTS: *J. F. S.* *Cattleya Percivaliana* and *Hæmarea discolor*, more frequently called *Good-ya discolor* in gardens. It is a very useful terrestrial Orchid, easily grown in an ordinary warm plant-house.—*A. S.* 1, *Cryptomeria elegans*; 2, *Osmanthus aquifolius*; 3, *Cun-ninghamia sinensis*; 4, *Cephalotaxus drupacea*; 5, *Retinospora squarrosa*.—*C. E. F.* *Bletia patula*. Please send better specimen of the other, with flowers.—*R. O. Y.* 1, *Isochilus linearis*; 2, *Epidendrum polypulbulon*; 3, *Stelis ophioglossoides*; 4, *Brassia verrucosa*; 5, *Cœlogyne sparsa*.—*E. C. C. D.* The variegated one is *Pteris cretica albo-lineata*, the other *Cyrtomium falcatum*.—*F. D., Cheshire*. 1, *Asparagus plumosus*; 2, *Pteris serrulata cristata*; 3, *Selaginella denticulata*; 4, *Cyperus alternifolius*; 5, *Cœlogyne cristata*; 6, *Cytisus racemosus*.—*T. G. S. W.* *Cypripedium venustum* and *Dendrobium Farmeri*.—*G. A.* *Primula* (next week); 2, *Begonia*, probably *fuchsioides*.

NARCISSUS EMPRESS: *J. C.* The reason is that no flowers were found in the bulbs last spring. The bulbs are apparently healthy and will flower probably next spring. Why no flowers were produced last spring is more than we can tell.

ORCHID FLOWER-BUDS FAILING: *W. J. N.* The statement which you give seems to point to the possibility of the temperature having fallen too low on some occasion, even if only for a short time. The fall in temperature was not sufficient to affect the *Odontoglossums*, but the other plants, which required more heat than *Odontoglossums*, and a drier air, were injured. Otherwise, foul air from the stove-hole, or other source, must have got into the houses.

ROSES FOR EXHIBITION: *P. F. P.* We do not think the conditions you mention would be suitable for growing Roses in pots for exhibition. Should you be able to find a more open position, you might try growing Roses in pots, but not for exhibition. We shall then be pleased to advise you as to the best varieties to grow.

TOMATO PLANTS: *Alpine*. The tiny seedlings are attacked with the "damping-off fungus" (*Pythium* sp.). You may secure sufficient plants for your purpose if you prick them out into fresh soil. If this is impossible, you must sow again in soil obtained from a different source. Other question next week.

FASTIGIATE TREES.

AMONG the aberrant forms of garden trees, those with a pendulous or weeping habit are, on the whole, much more appreciated than those with an opposite tendency. The reason for this is, I suppose, that the pendulous trees are more graceful and pretty than the others. There is also a certain kind of sentimentality about weeping trees which is pleasing to many minds. Still, if we value trees for the emotions they inspire, there is something to be said for the erect-growing kinds. To me, at any rate, few trees are more admirable than a well-grown, well-placed Lombardy Poplar, conveying, as it does in much the same way as a fine church spire, a sense of lofty aspiration.

The value of such trees, too, in the garden landscape is well known, relieving monotonous lines of vegetation as they do more effectually than anything else and enhancing, by contrast, the beauty and characteristics of other and different types of growth with which they may be associated.

There is one use to which some of these erect-growing trees might well be put, and that is for planting in streets. It is a common thing to hear people, especially those

who know nothing about the matter, reviling the way in which street trees in large towns are pruned—"mutilated" is the usual term. Yet, after a good many years' experience in pruning trees, I confess I do not see that it can be done much better than it is, as long as the present sorts of trees are planted. It is evi-

FIG. 66.—*QUERCUS PEDUNCULATA* VAR. *FASTIGIATA*, THE CYPRESS OAK.

dent that if two rows of big trees like Planes, Horse Chestnuts, Elms, and Limes are put into streets which a single row would more than fill if let alone, nothing but severe cutting will keep them within proper bounds. It strikes one, therefore, that trees naturally

of a narrower habit might well be given a trial. For instance, the Guernsey Elm preserves for many years a narrow, pyramidal outline, which the managers of our present street trees can only get by such a use of the knife and saw as makes the trees hideous for a considerable portion of their existence. The specimen of Guernsey Elm here illustrated (fig. 67) has never been pruned so far as I am aware, and I have known it for upward of twenty years. As will be noticed, it is still a comparatively narrow tree. All this, of course, applies more especially to the smaller cities and towns and to the outer suburbs of London. In the central parts of London and Manchester and other such cities, the Plane is by far the best tree for street planting, often, in fact, the only one.

Although nearly all our long-cultivated trees have sported into erect-growing, as well as pendulous forms, a great many of the former are but little known in gardens. It may be of interest, therefore, to bring together a few notes on some of these.

The propagation of these fastigate forms is most safely and conveniently effected by grafting, and the typical form should in each case be preferred as the stock. It is a curious fact, however, that several of them come partly true from seed, perhaps more frequently than is generally supposed. The Irish Yew and fastigate Oak are examples. Only a small proportion, however, come true, and to avoid waste of time waiting to see how the seedlings develop, most people prefer artificial modes of increase. Several varieties mentioned can easily be struck from cuttings, like the Yew, Lawson Cypress varieties, *Thuja gigantea*, &c.

QUERCUS PEDUNCULATA FASTIGIATA (Cypress Oak).—Although this tree has long been known in gardens (it is said to grow spontaneously in certain parts of South-western Europe), it cannot be described as a common or well-known one. Yet it is, as I think the accompanying illustration of a specimen at Kew will show, a very striking fastigate tree (fig. 66). In its leafless state it very much resembles the Lombardy Poplar, but it has the advantage of being longer-lived and freer from insect attack. In leaf and all other characters except habit it is like the common Oak. It is commonly known both here and in France as the Cypress Oak (*Chêne Cyprès*). There are several forms of this variety in cultivation—one with variegated leaves, another with tortuous branches, &c.—but none of them possesses a greater value than the ordinary pyramidal form except it be that called *viridis*, which is said to have leaves of a richer green. [There is a very fine specimen of the fastigate Oak in the gardens of the Trianon, Versailles.—ED.]

FAGUS SYLVATICA VAR. *FASTIGIATA* (Dawcyk Beech).—The common Beech has sported into quite a variety of pendulous forms, but until lately I had regarded it as one of the few common trees that had not developed an upright-growing one. The Kew collection, however, has acquired one during the past winter through the generosity of Mr. F. R. S. Balfour. It is a layer from a large tree growing at Mr. Balfour's place at Dawcyk, and as he desires the tree to bear that name I have pleasure in putting it on record.

ULMUS MONTANA.—The only really well-marked fastigate varieties of the Wych Elm are *U. montana fastigiata* (the "Exeter" Elm) and a yellow-leaved form of the same, sometimes known as *Ulmus Wredei*. Of neither of these could much be said in recommendation,

except that they are strikingly different from any other Elm. The finest Exeter Elm I know is in Canon Ellacombe's garden at Bitton. The trunk girths 11 feet at 5 feet from the ground. As a coloured leaved tree *U. Wredei* is not so useful as *Ulmus campestris* var. *Louis Van Houtte*.

variety for planting in streets has already been referred to (see fig. 67). Two small-leaved varieties of *U. campestris*, also erect in habit, are *Berardi* and *viminialis stricta*; they must, however, be regarded more as curiosities than anything else.

FIG. 67.—*ULMUS CAMPESTRIS* VAR. *WHEATLEYI*, THE GUERNSEY ELM.

ULMUS CAMPESTRIS.—There are several varieties of the common Elm which, whilst not exactly fastigiate, are of narrower proportions and much more erect in growth than the type. The best of them is what we grow at Kew as the Guernsey Elm var. *Wheatleyi*, although it does not seem to differ in any way from the so-called Hertfordshire Elm. The value of this

ULMUS GLABRA CORNUBIENSIS (Cornish Elm).—This tree, although not so pyramidal as the Guernsey or Hertfordshire Elm, is still very much more narrow in proportion to its height than the ordinary *Ulmus glabra*. It also would make a useful street tree.

BETULA ALBA PYRAMIDALIS.—So characteristic of the Silver Birch—the "Lady of the Woods"

—is the delicate grace of its pendulous twigs, that the columnar variety shown in the illustration (fig. 68) must be regarded as one of the most remarkable of the many varieties of that popular tree. I believe it is quite uncommon. Although such a variant from the type, it is in no way deficient in elegance, especially when, as in the picture, it is seen bending to the breeze (fig. 68). [We received a specimen from the late M. Van Volxem, which has now attained a considerable size.—ED.]

BETULA PUMILA FASTIGIATA.—The "Low Birch" is a native of North America, and this erect variety of it is also of American origin. It forms a columnar shrub 6 to 10 feet high, distinct, but of no particular merit as an ornamental plant.

ROBINIA PSEUDACACIA FASTIGIATA.—This curious tree, now seldom seen, is represented in the collection of Leguminosæ at Kew by a specimen 50 feet or so high. In habit it is one of the most erect and columnar of this class of trees, narrower, indeed, in proportion to its height than the Lombardy Poplar (fig. 69). Among the many curious varieties of the Acacia is one which has the divisions of each leaf reduced to three or even to one large leaflet only. It is called var. *monophylla*. Like the ordinary pinnate-leaved form this also has sported into a fastigate form, thus making a doubly curious tree. *W. J. Bean*.

(To be continued.)

MARKET GARDENING.

GRAPES.

Not only now, but all through the season, Grapes have been realising good prices. The only time when they have been very cheap was in the autumn, when growers were clearing their vineries for the housing of *Chrysanthemums*.

Lime is now largely used in market vineries, being freely forked into the borders. Neither Belgian Gros Colmar nor French Alicante are of the usual good quality, yet the former are making 2s. 6d. per lb.

No effort should be spared in inducing a free root action in the borders by feeding, &c.

At Messrs. Rochford's Turnford Nurseries, which I visited recently, some tons of Grapes are still hanging on the vines. The vineries are utilised for housing other subjects in boxes or pots, but ample precaution is taken to see that the vines do not suffer from their presence.

The promise of good crops of both Alicante and Gros Colmar was satisfactory.

Four-year-old planted vines of Alicante in the newer houses were not started, but the buds were swelling without heat. These houses are now filled with *Lilium longiflorum*. The above firm is realising 3s. 6d. per lb. for both Alicante and Gros Colmar.

All know that it is folly to allow Grapes to continue to hang on the vines unless they are of the best quality. Supplies of the best quality Muscats were never equal to the demand.

GRAPE THINNINGS.

These are now seen both from Worthing and Guernsey, and having very immature seeds are at their best conditions for tarts, &c. They are sure to meet with a ready demand.

FRENCH BEANS.

Good samples in $\frac{1}{2}$ lb. bundles are selling well at 2s. 6d. per lb. I note this, as it is too often said that English-grown Beans are not wanted. Present appearances point to a good demand, and one that will last until Easter is over.

ADIANTUM FERNS.

These are not grown so largely as formerly, hence those who have them are finding a good market. One grower in the trade informed me a few days ago that *Adiantums* in all sizes were his best line, and this I can well believe. *Stephen Castle*.

WILTON PARK, BEACONSFIELD.

A most pleasant run of about 40 minutes from Paddington, through scenery unsurpassed in the vicinity of London, brought me to Beaconsfield Station, and after a drive of about 15 minutes I came to the straggling, old-world village of the same name. From the eastern end of the wide street which forms the main thoroughfare may be seen the main entrance to Wilton Park. Dismissing the vehicle at this point, I walked about three-quarters of a mile to the gardens, where I was met by the energetic and genial head gardener, Mr. H. Perry. On walking through the park, which is pleasantly undulating, I was impressed with the fine specimens of forest trees, indicating in a marked degree the rich

FIG. 68.—*BETULA ALBA* VAR. *PYRAMIDALIS*.
(For text see page 150.)

character of the soil. There were noble specimens of Oak, Elm, and Beech; especially fine were the Oak and Beech, and though unquestionably of great age, they exhibited a vigour rarely seen in old trees. They contained no dead and decaying wood, therefore the roots have not suffered from the drought of recent seasons.

The mansion, at present in the occupation of Sir John Aird, Bart., is admirably situated on the crown of a gentle elevation, and commands a lovely view of a charming dell adjacent to the house, and a more extended view of the district known as Gerrard's Cross. It is a substantial-looking structure, and suggests comfort rather

than architectural grandeur. Formal flower gardening is not practised at Wilton, and with good reason, as the position of the mansion and grounds, with their ornamental trees, shrubs, Roses, and a few flower beds judiciously interspersed, convey a picture to the lover of pleasure ground effect such as could not be obtained from any amount of summer-bedding, however skillfully arranged. The present occupier, being a true lover of Nature and keenly observant, has planted clumps of choice Rhododendrons in positions from which the best effect can be obtained. These were planted freely apart in the grass, no formal beds having been made, though, of course, fresh soil was used in planting, and evidently this had been of the right kind, for, despite the extreme drought of the past season, the growth made was in every way satisfactory. I also noted a newly planted Cherry orchard, which in its own season will beautify the landscape.

On entering the kitchen garden, which is $5\frac{1}{2}$ acres in extent and which has been skilfully laid out, one is impressed by the evidences of a bygone art, viz., well-trained fruit trees. Here are to be seen Pears, Peaches, and Figs exhibiting in their growth an amount of vigour that is marvellous; but if any doubt should exist as to the age of the trees, the peculiar system of training which was a feature of the forties and fifties, is so well illustrated that any practical gardener readily arrives at their approximate age.

Here also was seen a splendid border of hybrid perpetual Roses. Rarely have I seen stronger growths, and that in varieties that are by no means strong growers generally; the pegging-down system is adopted here, and I have no doubt that when in full bloom the plants will present a feature of grandeur.

Herbaceous plants are here represented, not in massive clumps but in substantially laid out borders skirting the garden paths, and they are represented by the best known varieties of this useful family, especially those adapted for cut flower purposes.

Standard fruit trees, like those on the walls, are showing signs of age, but are still vigorous and produce large quantities of sound fruit, Cox's Orange Pippin being represented by many trees. The glasshouses are of the old-fashioned type and by no means suitable for present-day requirements; but already a start has been made to remodel this department, and a very nice range of plant-houses has been put up. On the occasion of my last visit these were well filled, one house being allotted to Souvenir de la Malmaison Carnations, of which Mr. Berry had a fine collection. The plants were in perfect health and absolutely free from "rust." Another house was devoted to the tree or winter-flowering section, of all of which Sir John Aird is a devoted admirer. These plants were also in excellent condition, producing abundant flowers, the well-known Enchantress being conspicuously fine.

Begonia Glôre de Lorraine, without which no garden seems complete nowadays, was occupying the front position of yet another house, while useful-sized plants of *Adiantum cuneatum* Fern filled the back stages. Stove and greenhouse plants, especially the most useful types, were well represented by healthy, clean stock, each seemingly getting the treatment suitable to bring out its best points.

I noted a great number of Roses in pots, which are in their turn placed under glass, and I was informed they were satisfactory in every respect. Violets, too, are grown in several frames, and like everything else in these gardens, were absolutely clean and flowering profusely. Mr. Berry has been very busily employed since taking charge of these gardens, in the planting before noted, and in putting the garden and other paths into a good condition. His efforts in

this respect speak for themselves, as the neat appearance of the newly-laid edging, with a liberal coating of gravel, and in some cases a foundation of ballast on the paths, gives the garden a neat appearance which cannot fail to please.

Mr. Berry's extensive and varied experience in some of the leading gardens of the country, not-

FIG. 69.—*ROBINIA PSEUDACACIA* VAR. *FASTIGIATA*.
(For text see page 150.)

ably Clumber, The Dell, and Dover House, now stand him in good stead; and I have no doubt were the principals under whom he served to see the garden now under his charge they would be highly pleased with the results of the performances of their old pupil. J. F.

THE STERILISATION OF SOIL.

(Continued from page 130.)

LEGUMINOUS PLANTS.

ANOTHER method by which free nitrogen is reclaimed from the atmosphere is by the combined action of certain species of bacteria and some of the higher plants. Green-leaved plants, other than those of the great family of Leguminosæ and a few others, are unable to make use of the free nitrogen of the atmosphere. It has been found, however, that Beans, Clovers, Peas, and other leguminous plants growing in soil poor in nitrogen obtained this substance from some source other than the soil in which they grow. This nitrogen has been found to be derived from the atmosphere. A leguminous plant develops upon its roots small nodules or root tubercles, and these are found upon microscopic examination to contain little colonies of bacteria. The plant and the bacteria together succeed in extracting the nitrogen from the atmosphere, which permeates the soil, and becomes fixed in the tubercles and the roots in the form of nitrogen-compounds. The result is that after a proper period of growth, the amount of fixed nitrogen in the plant is found to have decidedly increased.

The food cycle is a complete one. The food matter leaves the soil to enter the plant, from the plant it passes to the animal, from the animal to the bacterium, and from the bacterium through a series of other bacteria back again to the soil. Thus the condition of Nature and the existence of life is based upon the ubiquitous presence of bacteria, and upon their continual action and re-action in connection with both destructive and constructive purposes.

For the micro-organisms to carry on their work successfully, there must be a sufficiency of oxygen, warmth, moisture, and salifiable base in the soil. The soil must be permeable to gases, or the organisms will not develop and carry on their work. Moisture also must be present, but not in excess, for this will prevent the air from penetrating into it, and the organisms then work slowly or not at all. Warmth is all important, for, according to Schloesing and Müntz, soil-bacteria develop quickest at 99° Fahr., and are extremely feeble at a temperature below 49° Fahr., or above 122° Fahr. On the other hand, the fermentative bacteria, as in the case of those found in silos, and in fermenting beds and manure heaps, grow rapidly at a temperature of 140° to 160° Fahr.

The bacteria affecting agriculture and horticulture, so far as nitrate production is concerned, comprise those engaged in the decomposition of nitrogenous matter; the nitrifying organisms whose work is to oxidise the products of previous decomposition into nitrites and then into nitrates, and the nitrogen-fixing bacteria that appropriate the atmospheric nitrogen. They first thrive at a temperature of 140° to 160° Fahr., the nitrifying are most active at a temperature of 99° Fahr., and the nitrogen-fixing species carry on their work successfully at 50° to 65° Fahr. What, then, must be the effect of steaming or baking soil containing the all-important bodies known as bacteria?

STEAMING, BAKING AND SCALDING SOIL.

Steaming may mean any temperature from 212° to 1,146° Fahr., baking implies any heat above the normal up to a temperature of 1,141° Fahr., the heat of a common fire (Daniell), and scalding, a very old method of so-called sterilisation, any temperature above the ordinary up to 212° Fahr.; thus the maximum heat of scalding is the minimum temperature of steaming, and baking is seldom carried beyond that heat (212° Fahr.).

The process of scalding is performed wholly from above, that is, the soil or compost has the boiling water poured upon it, and this procedure means that whilst the immediate surface may receive the water at little less than 212° Fahr., the heat will gradually diminish as the

water penetrates or sinks into the soil, so that at a foot depth it certainly will not raise the temperature of the soil above the mean of the two—the boiling water (212° Fahr.) and that of the soil (say, 60° Fahr.), or 126° Fahr. This is 4° Fahr. more than the temperature (122° Fahr.) at which soil bacteria become, as we have seen, extremely feeble.

In baking the heat is not applied from above, except in the case of paring and burning, or burning rubbish or weeds on the surface, which practically sterilises the places of fire to the extent of prejudicing the crop, except as regards legumes, Clover, for instance, growing well where there has been bonfires, so that either the free nitrogen utilising micro-organisms are not killed, or the micro-organisms exist in the plant, that is, in the Clover seed. Baking may be done

ding, is not nearly so highly heated. The heat of this may be 180° to over 212°, but, as a rule, the compost being only baked on the outside, and then withdrawn, it is not more than 160° to 180° Fahr. inside, so that the putrefactive micro-organisms, though certainly prejudiced, as well demonstrated in the case of overheating of fermenting materials, or dung heaps, may not be destroyed, but the subsequent fermentation in case of the hotbed or manure is relatively feeble, and the putrefaction of organic matter in baked turves takes place very slowly for a time, the heating having a sort of preservative effect on the organic substances, so that baked soil does not give as good immediate result in growth as compost from similar turves that have been stacked until all vegetation has been reduced to the condition of mould and the decomposition carried to the extent of a large formation of nitrates of lime, potash, and soda in the heap. George Abbey.

(To be continued.)

PLEIONE YUNNANENSIS.

A LITTLE more than twelve months since Messrs. Sutton exhibited before the Orchid Committee specimens of this very pretty species which was referred to the Scientific Committee, where it at once received a botanical certificate as a new and interesting species in gardens. Shortly after this Mr. Rolfe described and figured the species in the *Orchid Review*, 1906, p. 81, fig. 10. The history of the plant and of its original discovery in the mountains of Yunnan by Mr. W. Hancock is given in the publication above cited. Quite recently we received from Mr. James Edwards a photograph taken by him from a plant growing in the collection of H. J. Elwes, Esq., with the information that it was grown in an intermediate house. The flowers are of a rosy-lilac colour and borne on a long stalk, hence it is suggested that the plant may be useful to hybridists as affording a means of lengthening the stem in some of its congeners. Whether that would be any improvement is a matter of individual taste. In any case *P. yunnanensis* is an interesting addition to a beautiful genus.

TREES AND SHRUBS IN SCOTTISH GARDENS.*

(Continued from page 118.)

DUNKELD.

No true arboriculturist would pass Dunkeld for the first time without making a pilgrimage to the two famous so-called "parent" Larches standing near the old cathedral. [See *Gardeners' Chronicle*, Feb. 12, 1876, p. 209.] They are the survivors of five trees planted there in 1738 by the then Duke of Atholl. It is a matter for regret that one of them is now dying, having, it is believed, been struck by lightning. The dimensions of the other are given on a tablet at its base: Height, 102 feet; girth at 3 feet, 17 feet 2 inches; girth at 68 feet, 6 feet 1 inch. Near the house are several other magnificent Larches, scarcely, if at all, inferior to this—one in particular was noticeable for its enormous bulb-like base, 8 feet in diameter.

Dunkeld is the original home of the Larch in Britain in more senses than one. It was here that the first plantations on a large scale were made, and the names of successive Dukes of Atholl in the 18th century will always be remembered as the pioneers of this branch of forestry. According to Hunter, in his *Woods, Forests, and Estates of Perthshire*, plantations of 27 millions of Larches were made by the fourth Duke alone—still known as "The Planter."

As is well known, Dunkeld is situated in a district of singular natural beauty, and the grounds are amongst the loveliest in Scotland. Lofty precipitous hills rise around them, and a charming grassy walk, broad and closely mown, winds by the side of the rushing Tay. The collection of Conifers is being added to, but the number of species represented by unusual

* Contributed to the *Kew Bulletin of Miscellaneous Information* by Mr. W. J. Bean.

(Photo by J. Edwards.)

FIG. 70.—PLEIONE YUNNANENSIS: FLOWERS ROSY-LILAC.

on a hot plate, or even in an oven or furnace, which in either case means that the soil receives greater heat at the part in contact with the hot plate, or at the outside of the compost in the case of the oven or furnace. When turves, for instance, are placed with their grass sides on a nearly or quite red-hot plate, over an improvised furnace of loose bricks outdoors, the turves being about 3 inches thick, and allowed to remain until the soil or upper surface is so hot that the hand cannot be comfortably placed upon it for more than a minute, there is not a heating of that part higher than 140° to 160° Fahr., or the temperature at which the fermentative bacteria not only live, but grow rapidly. In an oven or furnace the outside of turves may be browned, but the inside, as in a loaf of bread or a pud-

specimens is not great. The common Silver Fir, however, is in magnificent condition; one of them is estimated to be between 140 and 150 feet high. At Kew this tree can only be kept alive for a few years. There is also a fine *Thuja dolabrata*, 20 feet high, and not showing its usual disposition to become thin and lanky at the top. Of numerous well-grown hardy shrubs I noted *Kalmia latifolia*, 9 feet high and 12 feet through, finely in flower, and *Viburnum prunifolium*, 20 feet high.

BLAIR CASTLE.

This is another of the seats of the Dukes of Atholl, and, like Dunkeld, is one of the most beautiful places in Scotland. The gardens are picturesque, with fine views and very pretty avenues and drives, and to the west of the castle there is a magnificent gorge and a waterfall. An avenue of Silver Birch is so delightful that one wonders this tree is not more often used for minor avenues. The kitchen garden, too, is, I think, the most charmingly situated of any I have seen. It covers the opposite slopes of a valley, the bottom of which is filled by a large piece of water with islands in it. The grounds are furnished with many fine trees, but in size these are not equal to others elsewhere mentioned in these notes. There are several Larches here said to have been planted, like those at Dunkeld, in 1738. A most noteworthy tree is a specimen of the distinct and elegant *Abies magnifica*, 60 feet high, and in perfect health and form. *Abies Nordmanniana*, planted by her Majesty Queen Alexandra in 1872, is 45 feet high; and *A. nobilis*, planted by her six years later, is the same height. Both here and at Dunkeld *Larix leptolepis* is thought to be a promising forest tree. A plantation of this species mixed with a few others is making excellent growth; the trees were planted 17 years ago and some already girth over 2 feet.

INVEREWE, ROSS-SHIRE.

The house of Inverewe was built by Mr. Osgood H. Mackenzie in 1864 on what was then a bare hillside clothed with nothing bigger than heather and bracken. It is now surrounded at the back and sides by thick woods, 60 feet and more high, and gives an excellent example of what can be done, and what results obtained, in one man's lifetime—and he still in hale middle life. Mr. Mackenzie's garden, although not a large one (it is worked, I believe, by one or two men), has in recent years acquired a reputation as being one of more than ordinary interest. It is situated within a short distance of Poolewe, on the shores of Loch Ewe, and in the great parish of Gairloch, Ross-shire. It is, consequently, 20 to 30 miles farther north than Inverness. Yet there are growing here in great luxuriance trees and shrubs from Chili, New Zealand, South Africa, and the Himalaya, which near London have to be grown under glass. The climatic conditions, therefore, must be very similar to what obtain in S.W. Ireland and Cornwall, although no doubt the mean annual temperature is considerably lower.

In approaching the house one is struck by the number of Eucalypti sprinkled on the outskirts of the wood. They are mostly *E. coccifera*, and although but 10 years old are now 35 feet high. An interesting experiment might be made in this or some similar part of the country by planting an acre or two of this Eucalyptus, *E. Gunnii* and *E. urnigera*, under forest conditions. Nothing, except perhaps Poplar, could be got to grow faster, and the reproduction of an Australian gum-tree forest on even a small scale would be particularly interesting. It is also not improbable that the timber would prove of some value.

Mr. Mackenzie's rarer shrubs are planted in clearings of the plantations near the house. They are consequently well sheltered. Among Himalayan plants a representative lot of *Rhododendrons* have been planted, but although very healthy they are yet small. *Buddleia Colvillei*, however, the finest of all the *Buddleias*, was in flower. Since this species flowered for the first time in the British Isles with Mr. Gumbleton, near Cork, in 1892, it has done so in several other places in Ireland and England, but Inverewe must be one of the first places where it has flowered in Scotland. It was growing quite in the open.

There is a goodly number of New Zealand and Tasmanian plants here too, and a suggestive

indication of the character of the climate is afforded by the way in which they thrive. *Veronicas*, for instance, are coming up over the place from naturally sown seed, and *V. salicifolia* is 7 feet high. Rich as Scotland is in her Conifers, one would scarcely expect to find *Podocarpus Totara*—the "Totara" of New Zealand, and perhaps the most valuable of its timbers—growing out of doors. Yet here it is in perfect health. A plant of *Billiardiera longiflora*, 8 feet high, and trained up a tree trunk, was very prettily in flower, but it is even more attractive when followed by the crop of bright violet-blue berries. *Olearia Traversi* and *Leptospermum lanigerum* were both 8 feet high, and *Correa alba*, on a wall, was 6 feet high. *Olearia macrodonta* has, I believe, been very fine this year in Ireland and other mild districts. A fine bush, 14 feet in diameter, and some smaller ones were simply masses of white flowers.

Of Chilian shrubs I noted the following:—*Lomatia ferruginea*, often known as *L. pinnatifolia*, very healthy (I learnt that in another Ross-shire garden it was 10 feet high); *Mutisia decurrens*, the rare climbing Composite, in good condition; *Abutilon vitifolium*, 10 feet high, and flowering freely; *Azara Gilliesii*, *Escallonia pterocladon* (very charming here as elsewhere in Scotland), *Cestrum elegans*, *Tricuspidaria*, *Eucryphia cordata*, *Desfontainia spinosa*, and *Fuchsia* as hedge plants.

Of species from the Cape of Good Hope, *Phygelius capensis*, a bush 7 feet high, and a very healthy *Freylinia caestroides* were the most noteworthy that I saw.

DRUMMOND CASTLE.

The ancient seat of the Earls of Perth is about three miles out of Crieff, being set on an eminence and approached by a long narrow avenue of Beech and Lime. It is now one of the seats of the Earl of Ancaster, but the present residence is a modern building quite separate from, but close to, old Drummond Castle. This latter building (or, rather, what remains of it) is still in perfect repair, and from its highest tower a glorious view is to be had: mountain in the distance, wooded country and loch nearer, and, close beneath, the unique formal garden of Drummond. This garden, which is of an imposing and elaborate design and admirably kept, was originally planned and carried out in 1703 by a former proprietor and his gardener named Kennedy. The original design has been maintained for over 200 years, although additions have been made. The beds and masses are in geometrical form—triangular, circular, &c.—and they are largely filled with shrubs of various sorts kept low and flat, whilst the paths are bordered with a variety of shrubs clipped into narrow, columnar shape. These columnar trees are as good as any of the kind I have seen; they are now 80 years old, in excellent health and perfectly furnished. The plants used are Box, Yew, Purple Oak, Fern-leaved Oak, *Thuja occidentalis*, and the golden and silver varieties of Holly. The effect of the whole is impressive, especially when seen from the castle on its abrupt eminence above. This was, no doubt, the point of view of the original designer, for, like all examples of this type of gardening, it is the view as a whole that constitutes its chief *raison d'être*. Seen in detail, its lack of variety, the absence of light and shade, and its general monotony are apt to weary.

But the formal garden, whilst the chief feature at Drummond Castle, is not the only one. The fine Yews planted in 1703 are now enormous specimens with trunks 8 to 10 feet in circumference, and both Conifers and "hardwoods" grow finely here. Wherever one goes in Perthshire one hears about the great storm of November 17, 1893. Patriarchal trees that had withstood the gales of centuries succumbed that night, and whole plantations were levelled as if the trees had been so many nine-pins. Evidences of this terrible storm are to be seen even now in many parts of the country—uprooted tree stumps, decaying prostrate trunks, and bare hillsides. At Drummond a noble *Abies pectinata* was blown down, but the stump, 3 or 4 feet high, still stands where it grew. It shows that the tree was 210 years old and that its trunk was 6 feet 6 inches in diameter; it contained 1,010 cubic feet of timber. This must have been nearly, if not quite, the largest common Silver Fir in Britain of which there is any record.

An enormous Beech near by was seriously injured by the same gale; the trunk of this tree girths 19 feet 5 inches at its narrowest. Many other trees are in good condition here, but are not so notable as those seen elsewhere and mentioned in other parts of these notes,

(To be continued.)

The Week's Work.

THE HARDY FRUIT GARDEN.

By J. MAYNE, Gardener to the Hon. MARK ROLLE, Bicton, East Devon.

The Fig.—Unprotected trees, even in favoured Devon, have felt the severity of the winter. It will now be safe, however, to remove the protective material in order that the necessary pruning may be accomplished. Shoots that are more or less crippled by frost should be cut out entirely, if they can be spared, otherwise the damaged points should be shortened to an uninjured node. The embryo fruits can now be seen, and pruning must be regulated so as to preserve as many as possible. The old adage, "A pruned Fig tree is always barren," is scarcely correct, yet proper curtailment of the roots and extra care in disbudding dispenses largely with the need for the knife, and it is certain the less the latter is used the better will be the crop. In training, of which the fan shape is the best, allow a space of 6 inches between each shoot, for this will allow young growths to be "laid in" later where necessary. The Fig will bear good crops of fruits for several years without top-dressing, providing the trees are well fed with liquid manure during the time the fruits are swelling. This is much better practice than giving an annual top-dressing of rich soil, which would promote rank growth rather than an increase of crop. Top-dressings or mulchings should be applied in summer time while the fruits are swelling. At the present season fork in a light dressing of wood ashes and lime without disturbing the roots.

Strawberries.—These plants have also suffered from the effect of frost and cold cutting winds, which have turned the greater part of the older foliage quite brown. Cut away all these injured leaves, and destroy any weeds that are present. Young Strawberry plants are liable to become lifted out of the soil by frosts; they should therefore be made secure by treading.

The Pear Midge.—The larvæ of this pest lies buried beneath the ground under the trees from June to early April, at which time the flies emerge and attack the blossom. On cultivated ground it is possible to destroy the grubs by turning the top spit of the soil upside down during the winter and early spring months, and then making it very firm, so as to prevent them coming through just when the trees are in flower. A surface dressing of kainit in the month of June has also been recommended as a destroyer of this insect. This dressing may well be applied on grass land after it has been mown closely at the base of the trees. I have tried spraying before the flowers open, and again whilst they were in bloom, but with little success. Varieties especially liable of attack are Winter Nelis, Easter Beurre, General Todleben, and Marie Louise. By picking off the affected Pears on small and medium-sized trees and burning them, scores of the tiny white maggots may be destroyed.

Raspberries.—Shorten any canes that the frost may have injured, to a plump bud. Uninjured canes should be pruned to a desired height. Whilst it is inadvisable to allow recently planted canes to bear fruit the same season as planting, there need be no hurry in cutting them down, but rather wait until the new growths from the base reach a height of about 6 inches, when the old cane may be cut to within that distance of the ground. Treated thus, one would hear less of newly planted canes refusing to grow satisfactorily in the spring.

The Loganberry.—This American introduction is worthy a place in all gardens, and stools may still be planted. It requires similar treatment to the Raspberry, but being a rampant grower, the canes should be planted 5 feet to 6 feet apart in the row, so that the large leathery foliage may have space to develop. The fruit ripens about the middle of July, and proves most useful

either for tarts, jellies, or jams. The berries remain in good condition a long time on the plants. We are training some canes on a high north wall in conjunction with the Red Currant. The Rathburn Blackberry requires similar treatment to the Loganberry.

Newly-planted trees, whether against the wall or in the open, should now have all necessary pruning and training performed. The question of pruning newly-planted trees is a debatable subject; but experience has taught me that trees whose roots have been more or less curtailed in transplanting need similar restrictions to their growths above, so that root and branch are somewhat equally balanced. Growth necessary for the proper formation of the tree should be cut back to within 9 inches of their origin; the remaining ones should be spurred back to within two "eyes;" growths under 6 inches in length may be left intact.

THE FLOWER GARDEN.

By A. C. BARTLETT, Gardener to Mrs. Ford, Pencarrow, Cornwall.

Rose pruning.—In the milder parts of the country the coming week will be found a suitable time to prune most of the Roses. Where colder conditions prevail it will be wise to delay the operation for a week or more longer. Pruning of any sort should not be done during frosty weather. Unless the plants are in very good order, it will be found more satisfactory to use a pruning knife than the more expeditious secateurs. Each individual bush, even though of the same variety, requires different treatment, and it is therefore impossible to lay down any hard and fast rules for Rose-pruning. As a general principle, the stronger the shoot the less it should be pruned, and in dealing with such hybrid perpetuals as Abel Carriere, Duke of Edinburgh, Her Majesty, &c., stout growths made last season should be cut back to within about 6 inches of their starting point, and the weaker shoots on the same plant to within 2 or 3 inches. The less vigorous the leading shoot the closer back it should be pruned, so that such kinds as Alfred Colomb, General Jacqueminot, Marie Baumann, Madame Victor Verdier, &c., will flower all the better if their leading shoots are cut close back to a good, plump bud. Pillar Roses rarely require much pruning, it being, as a rule, sufficient to cut away the exhausted and dead branches. It is usually wise, however, to cut hard back all immature and weakly shoots upon Roses of any type.

Tea Roses, being more tender, should be left unpruned for three or four weeks longer. Although autumn is generally the best season for planting, it is often necessary, when dealing with cold, heavy soils, to delay the planting until the present time. Everything should be in readiness so as not to unduly expose their roots to the drying influence of the air. Plant firmly, and afterwards apply a mulch.

Edgings.—All blank spaces which may occur in box edgings should now be filled, well breaking up the old soil, and, if necessary, adding some fresh soil. Where there are no reserve plants, a strip on each side of the gap may be lifted, the plants divided, and used to fill up the vacant place. Any new edging necessary for herbaceous borders may now be laid. The fancy tiles sometimes seen are incongruous, and not to be recommended. The most harmonious edging to such borders is one composed of rough, local stone, broken to fairly even size and firmly laid. The spaces between them may be planted with a variety of dwarf, trailing plants, which will quickly cover the bare earth, and ramble partly over the stones, and also inwards between the taller-growing plants, forming a pleasant groundwork. If an edging composed wholly of plants is preferred, such species as Arabis and Aubrietia in variety, Double Daisies, Thrift, Gentianella, and dwarf Campanulas will be found suitable.

THE KITCHEN GARDEN.

By WILLIAM HONEST, Gardener to C. COMBE, Esq., Cobham Park, Surrey.

Sowing seeds.—Although the season for sowing early seeds is now well advanced, the weather until quite recently has been severe and altogether adverse to this important work. As recently as February 24 and 25, we registered as much as 15° and 13° of frost. In late localities and

on heavy soils very little seed-sowing can have been done in such conditions, therefore the sowing of such crops as advised in previous calendars must now be given the first consideration, in consequence of the satisfactory change that has taken place in the weather.

Broccoli.—A small sowing of such varieties as Michaelmas White, Shaw's "Winter" or "Self Protecting" should now be made, to be followed by another sowing at the end of the month or early in April. Early Turnips and Turnip-rooted Beet should also be sown in small quantities on a warm border, and given the protection of Spruce or Yew boughs, by simply laying them over the surface, and as these early sowings are by no means to be relied upon, further sowings must again be made at about the end of the month.

Cauliflower plants that have been wintered in frames will now require full exposure by day and increased ventilation at night, for they will by this time have become sufficiently hardy to withstand a few degrees of frost; continue to stir the surface soil frequently, and if a slight dusting of soot be given occasionally this will be of great assistance in keeping slugs in check.

Marrows.—Early Marrows, like all other vegetables that can be got in early, are much appreciated, and if seed of the Custard and Pen-y-Byd varieties be sown in heat, and either grown on in this way or planted out on a good hot-bed in a heated frame, they will produce good results.

Peas.—Dwarf varieties that were sown last November in sheltered positions will now be sufficiently forward to require the aid of short sticks. These will also afford considerable protection from any rough or cold weather which we may yet experience. Later batches that were sown in January or early in February will soon be ready for planting out in the open, and should now be getting well hardened in preparation for this. I prefer to place these in shallow trenches which have been previously got out and prepared by placing a layer of rotten dung at the bottom, and mixing a good dressing of wood ashes with the surface soil. If the Peas are planted thinly in these trenches, and short sticks are put to them at the time of planting, no further protection will be necessary, and the young seedlings will grow away without suffering a check.

Potato planting will be in progress in some of the more favoured localities, but bearing in mind the late severe frosts we have experienced the last two or three seasons, this should not be attempted without full consideration, and unless plenty of protection can be afforded the growths later on.

PUBLIC PARKS AND GARDENS.

By W. W. PETTIGREW, Superintendent of the Parks and Open Spaces in the City of Cardiff.

Trout rearing.—In addition to the scenic value lakes or streams may possess in public parks, they are also a great acquisition in being capable of affording under certain circumstances a number of additional pastimes for visitors. A pastime in point is fishing, and when this can be provided in a town park at a reasonable charge it is very popular. Needless to say, there is fishing and fishing, and its quality mainly depends upon the quantity and freshness of the water that has to be dealt with. If it has not a good circulation and is not of the very freshest character, it is at best only capable of supporting what are known as coarse fish, such as carp, chub, roach, rudd, and dace. On the contrary, if a lake is fed by a constant supply of good fresh water it should be suitable for stocking with trout. Anglers are generally agreed that few fresh-water fish give so much sport, or are so valuable for food, as the common brook trout; hence, whenever water is suitable for the maintenance of these, it should be stocked with them in preference to any of the coarse fish already mentioned.

Trout hatchery advisable.—It naturally follows that in public waters where a great deal of trout fishing is done, it is necessary to be more or less continually re-stocking. Under these circumstances, it generally means that either a large fee has to be charged to those who indulge in the sport, or that the authority who has charge of the water loses money by the provision of the fishing. To meet these difficulties—that is, to provide anglers with cheap but good

trout fishing without causing the town to be at a loss in consequence—there is nothing better than the establishment of a trout hatchery where practicable. To carry on such an institution successfully and at the minimum of cost, there are practically only two great essentials—a plentiful supply of clean fresh water and a stock of good breeding fish that can easily be captured when needed. Where these two requirements are fulfilled there is little difficulty in keeping the most heavily-fished waters well stocked by the aid of a hatchery. In one of the parks in this city we are fortunate enough to have a fresh-water lake 32 acres in extent which contains a plentiful supply of a good type of the brown brook trout. Although only 5s. per season is charged to anglers for fishing over this water—in consequence of which very large numbers avail themselves of the privilege—only once in fourteen years has it been necessary to pay for re-stocking it, and then only a very small sum was expended. The secret of the abundance of trout is that for a number of years past we have been carrying on a trout hatchery of our own, from which we have regularly stocked our lake and the adjoining brooks which run into, and from, it. As a short account of the methods adopted in carrying on the work of this hatchery may be of interest, and perhaps of service to some of the readers of this column, I propose to give a brief outline of our process of fish breeding.

Habits of the Trout.—Before describing this process, however, it may be as well for the benefit of those readers who are not familiar with this subject to mention a phase in the life history of the trout which will enable them the better to understand what follows. The brook trout, like its near relative the salmon, breeds during the winter months, and for this purpose, as a rule, travels up stream to the shallow gravel beds from about the middle of October to the beginning of January. The female trout (usually preceded by the male) burrows in the gravel near the surface of the water, lays her eggs over which the male sheds his milt, and then covers them up with the gravel. As copulation does not take place among fish the eggs are not fertile till after the milt is discharged in this way by the male, and it can readily be understood that it is not always possible for the milt to reach the eggs before it is carried away down stream, hence a large percentage of the trout ova laid in a wild state is infertile. A further check to the natural process of stocking streams and lakes is the fact that in addition to the ordinary enemies of trout ova that have to be contended with, trout themselves devour each other's eggs whenever they get the chance. Even the male trout, according to some observers, is as ready to eat the ova discharged by the female as to fertilise it. These facts show why it becomes necessary to artificially stock lakes and streams, which, although possessed of good breeding grounds, are not able to support the continuous fishing which generally takes place over public waters.

Percentages compared in the stream and in the hatchery.—It has been estimated that whereas in nature only about .2 per cent. of the ova laid by trout ever develops into adult fish, in a carefully managed hatchery which has plenty of roomy rearing ponds from 25 to 30 per cent. of the ova artificially incubated reaches the mature stage. This is surely an indication that fish hatcheries have a great future before them.

MR. JAMES MACDONALD, superintendent of the Montrose public parks and gardens, has been appointed superintendent of the Allenvale Cemetery, Aberdeen. The appointment involves the care of one of the most beautiful cemeteries in Scotland. Mr. Macdonald was formerly a director of the Royal Horticultural Society of Aberdeen, and also a director of the Aberdeen Chrysanthemum Society, being one of the founders of this last-named society. At the shows of the Royal Aberdeen Society and the Aberdeen Chrysanthemum Society he was a successful exhibitor.

MR. JAS. WHITE.—On Wednesday, February 27, in the Bothy at Southwark Park, the superintendent, Mr. James White, was presented with a marble timepiece by the employees as a mark of esteem and respect on his promotion to a higher rank in the service of the London County Council. Mr. White has been promoted to be first-class superintendent at Brockwell Park.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir TREVOR LAWRENCE, Bart., Burtford, Surrey.

Shading.—Already the warmth from the sun has on several occasions been sufficient to raise the atmospheric temperatures indoors considerably higher than is necessary for some of the plants, especially when it has shone during the middle hours of the day on those houses which have a direct southern aspect. The collection, as a whole, will require to be more closely shaded at this season than in the autumn; the young growths and leaves, which are now starting, being more soft and tender, are easily disfigured if exposed to strong sunshine. As regards shading generally, it is better to be on the safe side, and not unduly to expose rare and valuable plants to the sun's influence, at the same time it is advisable not to allow the blinds to remain down longer than is really necessary. Also, at this season, cold winds alternate with bright sunshine, and the external air, being perhaps several degrees below 40°, is unsuitable to be admitted with sufficient freedom to keep down the temperatures. On such occasions use the blinds. When the external air is above 45° and moist, afford more ventilation, and shade with discretion. These remarks are especially applicable to the cooler divisions, which contain such species as *Cypripediums*, *Odontoglossums*, *Oncidium*s, *Masdevallias*, &c. The Mexican house, if facing to the south, should have a thin blind, or the glass should be lightly stippled when the sun is really strong; if otherwise, no harm will accrue to the plants for several weeks to come. The *Cattleya* and intermediate houses will only require shading for an hour or so on that side of the roof which is exposed to the sun's rays. The tall-growing *Vandas* of the tricolor and *suavis* section, and which are now sending up strong flower spikes, should receive a little extra water at the roots, and be kept well damped between the pots; these plants grow well in the *Cattleya* house, but they should be shaded independently of the other inmates, as they are liable to lose a number of their lower leaves if exposed for any length of time to the direct rays of the sun. *Bolleas*, *Pescatoreas*, *Huntleyas*, and *Warscewiczellas* should also be closely shaded at all times.

East Indian House.—Most of the plants in the East Indian house will also require protection from the sun, especially species of *Aërides*, *Accolabium*, *Angraecum*, *Anoctochilus*, *Aracanthus*, *Lowii*, *A. Clarkei*, *A. Cathartii*, &c., that have recently been repotted or top-dressed. The different varieties of *Phalaenopsis*, *Bulbophyllum*, *Cirrhopetalum*, *Megacilium*, and the warm-growing *Cypripediums* will require similar attention. Other species as those of *Schomburgkia*, *Cyrtopodium*, *Lissochilus*, *Ansellia*, *Eulophia*, many *Dendrobiums*, terete-leaved *Vandas*, *Brassavola*, *Renanthera coccinea*, *R. Storei*, &c., appreciate a moderate amount of sunshine at all times. The handsome *Renanthera imschootiana* thrives best when elevated in a light position in the cool intermediate house. In the same structure the road-leaved *Maxillarias* and the Brazilian *Milnias* should be carefully shaded whenever the sun is bright, the foliage of the latter species being liable to turn far more yellow than is desirable.

Calogynes.—The warm growing *C. pandurata*, *asperata* (Lowii), *C. Meyeriana*, *C. peltastes*, and *C. Rossiana* are strong-growing plants and could be re-potted at this season. A rather damp, shady corner of the East Indian house will suit them admirably. Among the large number of species which thrive best in an intermediate temperature are the following: *C. elatior*, *C. barata*, *C. Gardneriana*, *C. graminifolia*, *C. firmata*, *C. conferta*, *C. Swainiana*, *C. Veitchii*, *C. virgatula*, &c. These are beginning to grow, and may now be potted should any of them require more root-room. *C. Massangeana*, *C. mentosa*, *C. Dayana*, and *C. flaccida* are species which produce overhanging racemes of blossoms; therefore, basket or shallow pans are preferred, as when suspended from the rafters their flowers are displayed to perfection. The last-named species being now at rest should not be disturbed until after it has bloomed. At the present time keep the compost rather dry, and when the spikes appear, afford water copiously. All the species mentioned grow well in a mixture of peat and sphagnum-moss, pro-

viding it is well drained; but as neither of them make large quantities of roots, their receptacles should be small as a rule. Such species as *C. speciosa*, *C. s. alba*, the new *C. Lawrenceana*, *C. cristata* and its varieties *Lemoniana* and *hololeuca*, &c., which are coming into bloom, should be well supplied with water at the root until the flowers open, taking care not to wet the flowers, as they are liable to become spotted.

PLANTS UNDER GLASS.

By J. G. WESTON, Gardener to H. J. KING, Esq., Eastwell Park, Kent.

Carnation Souvenir de la Malmaison.—Young plants that have been wintered in small pots should now be given a final shift into others of 6-inch diameter, which size is, as a rule, sufficient for the plants in their first season of flowering. A suitable compost is formed of three parts good turfy loam and one part leaf-soil, some old mortar rubble, charcoal and sand, and a 48 size pot full of soot to each barrow-load of the mixture. Water judiciously at all times, and especially after re-potting, for very little moisture will be required at the roots until they have become active in the new soil. If any trace of rust fungus is seen, cut off and burn every particle of the affected foliage. These plants should be kept in a fairly cool atmosphere, and they will then provide a succession of flowers when those of the older plants are finished. Established plants may be hastened into flower by providing a temperature of 55° to 60°, with a little ventilation at all times; on no account allow the atmosphere to become close and humid. *Duchess of Westminster* flowers, naturally, several weeks earlier than most varieties. *Maggie Hodgson* has large dark-coloured flowers, and is a variety worthy of notice.

American Tree Carnations.—Early batches of these plants will now be ready for transferring singly into 3-inch pots, a light sandy soil being recommended as a rooting medium. Place the plants on a shelf near to the glass in an intermediate temperature, and endeavour to obtain them as robust as possible early in the season. Continue the propagation of these plants. Two of the best varieties are *Britannia*, a grand scarlet flower, and *Mrs. H. Burnett*, a lovely shade of salmon-pink.

Fuchsias.—Pruned plants placed in a moderately warm house will soon provide suitable growths for the making of cuttings, which, if inserted in light sandy soil in a propagating frame, will quickly form roots, and provide good plants for flowering in the autumn months. Young, actively-growing *Fuchsias* intended to be grown as large specimens should be transferred to larger pots, and afterwards be placed in an intermediate temperature. The potting soil should consist of a liberal mixture of equal parts turfy loam, leaf-soil, and old Mushroom-bed manure, with the addition of sand. When the pots are filled with roots, strict attention must be given to the matters of watering and feeding.

FRUITS UNDER GLASS.

By ALEXANDER KIRK, Gardener to J. THOMPSON PATON, Esq., Norwood, Alloa, Clackmannanshire.

The Vinery.—The planting of one-year-old vines, in both new structures and in older houses that are being re-planted, should be pushed on, as the month of March is the best time for this work. The border, which should be 3 feet in width and 2 feet in depth, should have a solid bottom of concrete, and on this should be placed a layer 8 or 10 inches in thickness, of broken bricks, coarse lime rubble, or similar material. On this a layer of fresh whole turves with their grass sides downwards should be laid, and upon this the compost, which should consist of good turfy loam, roughly chopped, a liberal quantity of lime rubble—which has been passed through a sieve with a half-inch mesh—and some wood ashes. To each three tons of this compost add about 1 cwt. of coarse grade vine- and plant-manure. Mix the whole thoroughly together, and when ready fill in the border, making it firm as the work proceeds. The roots of young vines should be well soaked with tepid water previous to planting. Spread out the roots and plant the vines at a distance of 3 feet 6 inches apart, and at a depth of about 6 inches below the surface of the soil. Secure

the canes loosely to a stake, and when finished give a good soaking of warm water, and afterwards a mulching 2 inches deep of moss-litter manure. Damp the paths two or three times daily, and keep the house close, and warm with sun heat. Do not apply fire heat unless the nights are very cold. Allow the vines to break slowly.

Early Melons should now be ready for planting in the borders in the pits. The compost should consist of chopped turfy loam, heavy in texture if obtainable, as Melons succeed best in a rather stiff loam. Add some sifted lime rubble to the soil, and to each barrow-load of this mixture add a 5-inch potful of fine grade vine- and plant-food. Place turves grass side downwards over the drainage material, next a 2-inch layer of horse manure, and then the compost to a depth of 18 inches. Make the soil very firm, and as soon as it has become warmed to the temperature of the pit, plant the Melons 18 inches apart, taking care not to place the neck of the plant below the surface of the soil. Train them as single cordons, allowing two or three fruits to develop from each plant. Give them a copious watering with water at a temperature of 70°, and damp the plants twice daily with tepid water through a fine rose. Maintain a temperature in the pit of 60° at night time and 70° by day, with a steady bottom heat of 75°.

Late Peach and Nectarine trees in houses which have been cleansed, and whose shoots have been pruned and tied to the trellis, are now in readiness to be started into growth. If any signs of bud-dropping appear, test the borders with the soil tester, and if dry, give a good soaking with tepid water. Open the ventilators and leave them open by day and night.

Fruit-trees in pots, including Plums, Nectarines, Pears, &c., intended for the first crops should now be selected from the stock of orchard house trees. Place the pots in a row on the floor of a Peach-house, in which artificial heat is afforded at night time only. Water carefully, a caution which should always be observed in the case of dormant fruit trees in pots.

THE APIARY.

By CHLORIS.

Artificial feeding.—Many beekeepers imagined that because the weather was remarkably fine during September last that there was no need to feed, and if they do not hasten to repair the neglect they will have trouble during the coming summer. The winter has, on the whole, been severe, and the bees may not have consumed so much food as they would have done during a warmer winter; still, attention to the food for the remainder of winter and early spring is imperative. It is of the utmost importance that no food of a stimulating nature should be given—that is, no honey and water or syrup must be placed above the frames. This would induce early breeding, and should we experience another cold snap, many of the bees would be killed.

The entrances to the hives need attention, as they may become blocked by dead bees, and this will prevent the others from taking a cleansing flight when the weather permits. This is of the utmost importance to the well-being and health of the colonies.

What to feed on.—The very best food now is a frame of sealed honey, containing, as it does, the natural food of the bees, but if this cannot be had then substitute candy. This is generally made by boiling the sugar until it is set, so that its surface may be easily scratched with the finger nail. It may also be made by kneading crushed loaf sugar in warm honey until the consistency of a stiff dough has been reached.

Dampness.—It is well to examine the hives to discover whether the roofs have been leaking; if so, the quilts must be changed and the damaged roofs repaired. There is no more fruitful cause of dysentery among bees than dampness. Dysentery is seen in the fact of the excreta of the bees being found on the alighting boards.

Examine the colonies on a bright, warm day when the sun is shining, and do it as expeditiously and as thoroughly as possible, so that the true state of each hive may be ascertained.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

Illustrations.—The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, MARCH 11—Ann. meet. Unit. Hort. Ben. & Prov. Soc. at R.H. Hall, Westminster.

WEDNESDAY, MARCH 13—Winter-flowering Carnation Soc. Exhib., Regent's Park. International Hort. Exhib., Nice, opens.

SATURDAY, MARCH 16—German Gard. Soc. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—41°0'.

ACTUAL TEMPERATURES:—LONDON.—Wednesday, March 6 (6 P.M.): Max. 50°; Min. 38°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, March 7 (10 A.M.): Bar., 30.2; Temp., 46°; Weather—Overcast.

PROVINCES.—Wednesday, March 6 (6 P.M.): Max. 47° Cornwall; Min. 41° England, N.E.

SALES FOR THE ENSUING WEEK.

MONDAY—Roses, Perennials, Lilliums, Azaleas, &c., at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.

TUESDAY—Duplicate plants from the "Chillingham" collection of Orchids, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 1.

WEDNESDAY—Azaleas, Border Plants, Lilliums, Palms and Plants, at 11: 4,000 Roses and Fruit Trees at 1.80 and 4; at 67 & 68, Cheapside, E.C., by Protheroe & Morris. Plants, Roses, and Lillies, at Steven's Rooms, King Street, Covent Garden, W.C.

THURSDAY—The "New Hall Hey" Collection of Orchids at New Hall Hey, Rawtenstall, near Manchester, by Protheroe & Morris, at 1.

FRIDAY—Lilliums, Herbaceous Plants, Roses, Azaleas, &c., at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12; Choice Imported and Established Orchids in large variety, at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

Plant Nomenclature.

It must not be thought that botanists and gardeners have any monopoly in the matter of unpronounceable names. The chemists have followed the plan, the principle of which (allowing for some exceptions) is objectionable. A name, as a rule, should be nothing more than a name, a convenient means of speaking or writing of some thing or some organism, as separate from some other thing or organism. Previous to the time of Linnæus, botanists made use of a descriptive phrase containing perhaps a dozen or more words. Linnæus adopted the plan of giving to each animal or plant two names, one that of the genus (the surname), the other that of the species, the specific name analogous to the baptismal name. That is simple and intelligible, and we do not find, in practice, that those who are really interested in plants and want to know something about them, even if only for commercial purposes, have any particular difficulty in accommodating themselves to the use of a "barbarous" nomenclature. Every science, every trade has its own vocabulary, which has to be learnt, and the convenience of which, when learnt, completely outweighs the initial difficulty of acquiring it.

Complications arise when endeavours are made to make the name express some quality or attribute possessed by the plant or animal. If we could be sure that the particular attribute was absolutely peculiar to the plant, then it would be convenient to adopt such a qualifying name. Thus if only one Rose were spiny, it would be convenient to call such a Rose, *Rosa spinosa*, but, as a matter of fact, nine-tenths, or perhaps more, Roses are spiny, and to name one species *R. spinosa* is misleading. There are many Roses, for instance, that are quite as spiny as that called "spinosissima." The same objection applies to the use of vernacular names. There are plenty of Roses in Scotland besides that one called the "Scotch Rose," which, so far from being confined to Scotland, is met with all over the northern hemisphere of the old world! As a general rule (subject to a few exceptions), popular or vernacular names are a nuisance and a hindrance to study, and, of course, they are mostly useless when dealing with plants of another country where the language is not the same as our own. We have said, however, that there are certain cases where a popular name is more convenient than one of a more scientific character. We take an illustration from the druggist's shop. There can be no doubt what is meant by "calomel" or by "corrosive sublimate," respectively, but these substances have been called chloride, bi-chloride, sub-chloride, perchloride of mercury and mercuric subchloride. Former generations adopted one of these epithets, the moderns make use of another, the change being necessitated by increased knowledge. Calomel is now subchloride of mercury, corrosive sublimate is perchloride of mercury, but the two vernacular names have fortunately never been changed in accordance with the progressive increase of scientific knowledge.

We stated at the beginning of this note that gardeners or botanists had no monopoly of hard names. We give an illustration of this assertion taken from the *British Medical Journal*, one, moreover, which amply justifies our contention that a name should be a name, a name only, and not a description.

"The systematic names by which certain compounds are known to chemists are usually of a length that precludes their use for ordinary purposes of commerce or in prescribing; such names, for instance, as dipar-anisylmonophenetylguanidine or diethylglycocolpara-amidohydroxybenzoylmethylster, however informing to the organic chemist, are clearly impracticable for ordinary use."

We do not think the Orchid-hybridists even can beat these.

OUR SUPPLEMENTARY ILLUSTRATION.—The photographs from which the supplement to this issue has been prepared depict very clearly two interesting scenes in the life of an Orchid collector. The upper picture shows a small mountainous village, which has been for a time the collector's headquarters. On his arrival he had sent natives to all the surrounding districts, and has succeeded in obtaining a large quantity of *Cattleya Trianae*, and with these he is just starting on an arduous journey to a river-port whence the plants can be shipped in cases. The photograph shows the only means of transportation that can be adopted in these mountainous districts. Each mule is laden with two large "panniers"

containing the plants. No roads exist, merely a track over range after range of mountains and hills, a rugged and oftentimes treacherous path, interrupted at frequent intervals by a river or mountain stream. When these are swollen by heavy rains the crossing becomes a matter of difficulty and of danger, and the collector considers himself fortunate if he arrives without loss of some of his plants, or even of his mules and their drivers—a by no means rare occurrence. On arrival at the river port, the plants are finally prepared for packing into cases for shipment to London, as is depicted in the lower picture. The central figure is Mr. LOUIS FORGET, one of Messrs. SANDER & SONS' principal collectors, who for nearly 20 years has travelled to and fro through almost all the countries of Southern and Central America, from the arid highlands of Mexico, the mountains of Colombia and Venezuela, to the great grass plains of the Argentine. As may well be imagined, he has met with dangers and difficulties, but his coolness and skill have never failed him. At one time a would-be assassin's bullet passed through a hut in which he was staying; at another he floated unharmed over the countless rapids of the Rio-Saõ Francisco in a native canoe. Amongst many "finds" one of the most important was the re-discovery of *Lælia Jongheana*, and it was he who sent the *Nicotiana Forgetiana*, the parent of the several new hybrids of *Nicotiana* that have been distributed in recent years.

THE BOTANICAL MAGAZINE.—The plants illustrated in the March number are:—

ALOE PALLIDIFLORA (Berger), tab. 8,122.—A species which flowered in Sir THOMAS HANBURY'S garden at La Mortola, where it was obtained from the Berlin Botanic Garden. Its native country is not definitely known. The fleshy leaves are in tufts, brownish green, linear-lanceolate, with a long acumens, margins with scattered incurved pinkish spines; flowers numerous in branching panicles each about 2 cm. long, tubular, pinkish with streaks of a darker hue, lobes small, spreading, reddish.

BLEPHAROCALYX SPIRÆOIDES (Stapf), tab. 8,123.—A Brazilian Myrtaceous shrub with linear dotted leaves recurved at the margins and numerous yellowish flowers disposed in terminal, much branched cymes; berries purplish red the size of small peas. The plant is only known at present in its cultivated state. It requires warm greenhouse treatment.

PRIMULA DEORUM (Velenovsky), see *Gardeners' Chronicle*, 1905, vol. xxxvii, p. 98, fig. 44. W. B. Hemsley, in *Botanical Magazine*, tab. 8,124.

CAIOPHORA CORONATA (Hooker & Arnott); Sprague in *Botanical Magazine*, tab. 8,125.—A trailing Loasaceous herbaceous plant with terete, decumbent stems covered like the foliage with stinging hairs; leaves on long stalks much divided; flowers solitary terminal on long erect stalks; flowers about 2 inches long and rather more broad, petals five, boat-shaped, white distinct, but forming a lobed cup-shaped corolla. It is a native of the Andes at altitudes of 9,000 to 14,600 feet from the Argentine Republic to Peru. The present figure was taken from seeds collected in Argentina by Mr. ELWES, but it had been previously introduced into gardens under the name of *Blumenbachia coronata*. The plant is decidedly attractive, but requires to be handled with caution.

PAPHIOPEDILUM VILLOSUM (Pfitzer) var. ANNAMENSE, Rolfe in *Botanical Magazine*, tab. 8,126.—A variety of the old *Cypripedium villosum* introduced from Annam by Messrs. SANDER & SONS, and differing from the type, which is a native of Burma, in its longer and narrower leaves and in the dorsal sepal, which is represented as whitish with the centre of the disc occupied by a large purplish blotch with veins of a darker hue, the whole edged with a narrow band of green. Kew.

ORCHID COLLECTING IN COLOMBIA FOR MESSRS. SANDER & SON.

2. The second part of the document focuses on the implementation of the proposed changes. It details the steps involved in the process, from the initial planning stage to the final execution. The author highlights the challenges faced during the implementation and provides solutions to overcome them. The text also discusses the role of the management team in ensuring the successful completion of the project.

3. The third part of the document presents the results of the study. It includes a detailed analysis of the data collected, showing the impact of the proposed changes on the organization's performance. The author compares the results with the initial objectives and provides a clear conclusion on the effectiveness of the changes. The text also discusses the implications of the findings for future research and practice.

4. The fourth part of the document provides a summary of the key findings and conclusions. It reiterates the importance of accurate record-keeping and the successful implementation of the proposed changes. The author also provides recommendations for further research and practice, based on the findings of the study. The text concludes with a statement of appreciation for the support and assistance provided by the management team and the research team.

ROYAL HORTICULTURAL SOCIETY.—*General Examination.*—The society's annual examination in the Principles and Practice of Horticulture will be held on Wednesday, April 10, 1907. Candidates should send in their names not later than March 25. Full particulars may be obtained by sending a stamped and directed envelope to the society's offices, Vincent Square, Westminster. Copies of the questions set from 1893 to 1905 (price 1s. 9d.; or 10s. a dozen) may also be obtained. The society is willing to hold an examination wherever a magistrate, clergyman, schoolmaster, or other responsible person accustomed to examinations will consent to supervise one on the society's behalf. In connection with this examination a scholarship of £25 a year for two years is offered by the society to be awarded after the 1907 examination to the student who shall pass highest, if he is willing to accept the conditions attaching thereto. The main outline of these conditions is that the holder must be of the male sex, and between the ages of 18 and 22 years, and that he should study gardening for one year at least at the Royal Horticultural Society's Gardens at Wisley, conforming to the general rules laid down there for students. In the second year of the scholarship he may, if he like, continue his studies at some other place at home or abroad which is approved by the council of the Royal Horticultural Society. In case of two or more eligible students being adjudged equal, the council reserve to themselves the right to decide which of them shall be presented to the scholarship.

—*School-Teachers' Examination.*—The society will hold an examination in Cottage Gardening on Wednesday, April 24, 1907. This examination is intended for and is confined to elementary and technical school-teachers. Medals and certificates are awarded and class lists published in connection with these examinations, and the syllabus may be obtained on application to the Secretary, R.H.S., Vincent Square, Westminster, S.W.

FLOWERS IN SEASON.—Mr. BEDFORD obligingly sends us from Straffan, Kildare, fine samples of *Galanthus plicatus* "Romeo," with very broad ($1\frac{1}{2}$ inch) plicate, glaucous leaves. The outer perianth segments are spreading, broadly oblong, fully an inch in length, pure white, the inner ones about half the length, overlapping so as to form a tube, white at the base, notched at the apex and marked in the upper part with a deep green band, edged with white. *Galanthus Imperati niveus* has oblong, linear, glaucous leaves half-inch across, folded in the middle (conduplicate), channelled on the upper surface with a prominent midrib beneath. Outer perianth-segments $1\frac{1}{2}$ inch long, linear-oblong, tapering at the base, inner segments oblong, truncate, notched white with a green heart-shaped blotch.

WINTER-DRESSING OF FRUIT TREES.—In place of the lime wash which is such a disfigurement to fruit trees, French fruit-growers are making use of lysol, a preparation of carbolic acid, in the following proportions: lysol 4 litres (1 litre = $1\frac{1}{2}$ pint); water 1 hectolitre = 22 gallons. This is freely applied to the stem and branches with a brush. It kills the insect pests, destroys the lichen (moss), and greatly contributes to the health of the tree.

COLONIAL NOTES.—*Report of the British Guiana Botanic Gardens for the year 1905-6.* Mr. BARTLETT records much useful work, somewhat hindered by drought. The herbarium specimens are receiving careful attention and a catalogue of them is being made.—*Annual Report of the Agricultural and Horticultural Society of India, 1905.* The president, Mr. EGGAR, speaks of satisfactory work and the completion of Rose fields containing over 8,000 healthy plants. The journal includes some valuable cultural notes intended to help local growers.

SECRET COMMISSIONS.—The first case, so far as we know, of the application of this law is one reported recently in the *Pharmaceutical Journal* as follows:—Secret Commission.—In the Wandsworth County Court on Monday, February 18, the plaintiff brought an action to recover from the defendant the sum of £68 4s. for pipes supplied. The case for the defence was that the purchase was arranged by one of the defendant's agents, who, the defendant had since discovered, was going to get $2\frac{1}{2}$ per cent. from the plaintiff for arranging the contract. The promise of this secret commission broke any agreement that had existed. Judge Russell upheld this contention, and gave judgment for the defendant, with costs.

TULIP.—Messrs. J. BACKHOUSE & SON send us a Tulip in which the scape, which usually bears a single flower at the extremity, divides into three branches, each bearing leaves and a terminal flower. At first sight the appearance is that of a fusion of flower-stalks, but successive sections across the stem, from the base upward, show that while it is undivided below, it becomes branched above.

NATIONAL SWEET PEA SOCIETY'S AFFILIATION SCHEME.—The committee has decided upon the following scheme of affiliation: Societies subscribing 10s. 6d. per annum are entitled to:—1, One of the National Sweet Pea Society's Silver Medals, to be offered as a prize for Sweet Peas only; 2, One copy each of the Society's *Annual* and other publications; 3, One ticket of admission to the Society's London Exhibition; 4,

FIG. 71.—MEDAL OF SWEET PEA SOCIETY.

To nominate one of its members to represent it at the annual and other general meetings of the Society. Committees wishing to take advantage of this scheme should make application to and forward a remittance to the Hon. Sec., CHARLES H. CURTIS, Adelaide Road, Brentford, Middlesex. We reproduce an illustration of the medal the Society is prepared to issue.

TOBACCO-RAISING.—Mr. HAWES, of the Royal Botanic Garden, Regent's Park, has now under his care a number of seedlings representing many of the finest commercial varieties of Tobacco, which it is hoped to display at the International Tobacco Show in April.

M. GLAZIOU.—The *Kew Bulletin* (No. 2, 1907) has succeeded in obtaining some information relating to this energetic collector, who died in March last near Bordeaux. M. GLAZIOU, it appears, was born in Brittany in 1828, and spent 35 years of his life in Brazil. He was director of the public gardens of the city of Rio. The extent of his collections in various provinces of Brazil may be estimated by the fact that he collected about 12,000 species represented by some 200,000 specimens, the first set of which went to von Martius and subsequent editors of the *Flora Brasiliensis*, and a large number are to be found at Kew.

THE NATIONAL POTATO SOCIETY.—The schedule for the forthcoming show has been issued, and it will be seen that the exhibition is to be held at the South-Eastern Agricultural College, Wye, Kent, on October 2, instead of five weeks earlier as first suggested. This arrangement is far better, and will tend to create greater interest in the event. Altogether there are 36 classes in the schedule, and a number of special prizes are announced, but the committee reserve the right to cancel classes if their funds are insufficient. Copies of the schedule may be obtained from the hon. sec., Mr. W. H. ADSETT, Hatton House, Great Queen Street, London, W.C.

ANNUITY FOR A GARDENER.—Mr. JESSE WILLARD, for forty-two years head gardener to the late Baroness BURDETT-COUTTS, at Holly Lodge, Highgate, has been provided with a pension of £105 a year by Mr. BURDETT-COUTTS, the husband of the late Baroness, who made no specific provisions in her will for her servants, knowing that Mr. BURDETT-COUTTS would understand her wishes in such a matter.

THE SURVEYORS' INSTITUTION.—At a meeting held on February 25 a paper was read by Mr. AUBREY J. SPENCER, barrister-at-law, on "The Agricultural Holdings Act, 1906." The next ordinary general meeting will be held on Monday, March 18, 1907, when the discussion on Mr. AUBREY J. SPENCER's paper will be resumed. The annual dinner of the institution will be held at the Whitehall Rooms, Hotel Metropole, on Tuesday, April 16, 1907, at seven o'clock precisely.

OLD TRAFFORD GARDENS, MANCHESTER.—Only one vote was recorded against the project for changing the character of the Royal Botanical Gardens, Old Trafford, at the annual meeting of the proprietors held recently, and the gardens will therefore be leased to a company for 10 years at an annual rental of £2,000. It is proposed to convert the gardens into an amusement resort. The lease provides for the maintenance of the glass-houses, and the collection of plants. The palm-house is to be a tea-room, the long range of buildings running nearly the whole length of the western side, which were part of Manchester's great exhibition, will be used for restaurant, dancing-hall, and roller skating rink. There will be a new illuminated fountain and other attractions.

CENOTHERA.—The publication by MM. LEVEILLE and GUFFROY of a monograph of this genus is announced. We shall be curious to see how the "mutations" from *CE. Lamarckiana* are treated, and whether Prof. DE VRIES' "new species" are accepted by the monographers.

THE SOUTH AFRICAN EXHIBITION AND THE R.H.S.—Opinions were very much divided upon the question whether the admixture of Colonial products with the floral exhibits on Tuesday last, was an advantage or not. Those who were precluded from exhibiting felt sore at their exclusion, particularly when they saw that others had been admitted. Some who worked hard to secure a hall for horticulture were not well pleased to see it made use of for other purposes. Others were grateful for the break in the monotony of these exhibitions. An explanation was offered of the reasons why the change was made. We think we shall sufficiently gauge the prevalent feeling if we say that the verdict was "not guilty, but don't do it again."

THE LATE PROF. PFITZER.—We note the appearance of a short biography, by Herr G. FISCHLER, of the late ERNST PFITZER, of Heidelberg. The account of his life's work is made more complete by the addition of a list of his botanical writings, and the pamphlet also contains an excellent portrait of Herr PFITZER.

MENDELISM.—A second edition of Mr. R. C. PUNNETT's little book on this subject has been issued by Messrs. Macmillan. How valuable it is to hybridists and those concerned in the scientific study of hybridity may be illustrated by an extract from the preface:—"Why the dwarf pea sprung from tall ancestors breeds true to dwarfness; why the progeny of a black and white rabbit are in one case all black, and in another all of the wild grey colour, why the 'pure' blue Andalusian fowl must ever remain a mongrel, these and other seeming paradoxes were clear two years ago. But why two white Sweet Peas should give a purple, and why two hairless Stocks should revert to the hairy form—these were questions that were then unsolved. That experiment would give us the solution we

LAMARCK.—It is proposed to erect in the Jardin des Plantes a statue to the famous naturalist whose scientific career was mainly passed in the Natural History Museum. It is curious to see how LAMARCK, who was one of the pioneers of the doctrine of evolution, is now to be honoured, while in his lifetime and long afterwards his theories met with no acceptance.

Publications Received.—*Introduction to Plant Ecology*, by Rev. Prof. Henslow. Stanford, Long Acre.

TREE-FERNS IN SIKKIM.

IN connection with Sir George Watt's "talk" at the Horticultural Club, we take the opportunity of reproducing a photograph, from Messrs. Johnston and Hoffmann, of 81, Devonshire Street,

WINTER WORK IN FRUIT PLANTATIONS.

II.

THE attack of birds upon Gooseberry buds this season was first noticed on December 19, the bushes having been inspected nearly every day from the beginning of that month. This early attack, however, was only upon a small piece near the farmyard, where sparrows abound. In a more distant plantation the first damage was noticed on January 17. In each case spraying was begun on the day following the discovery of the attack. In some previous seasons the damage done by birds has been so serious, and the difficulty of preventing it is so great, that I shall never plant another acre of Gooseberries, unless I can devise a more complete preventive

FIG. 72.—TREE-FERNS IN SIKKIM.

were confident, and our confidence has been justified by the event. The Sweet Pea and the Stock have yielded up their secret, and we are at last able to form a clear conception of the meaning of reversion. . . . As year follows year, and experiment succeeds experiment, there is forced upon us a sense of what it all may come to signify for ourselves of the tremendous powers of control that a knowledge of heredity implies. To-day we are only at the beginning. The prologue is nearing completion, the drama is yet to be written—and played." A quotation from Shakespeare is sufficiently remarkable:—

" . . . his humour

Was nothing but mutation,"

but it is not to be supposed that this can in any way be taken as an anticipation of DE VRIES!

W., showing a group of Tree-ferns near Darjeeling. As we have no specimen before us, it is not possible to say what the species or even the genus may be. In any case the plants are remarkable, not only for their picturesque appearance, but for the circumstance that the stems are branched. Species of *Cyathea* and *Alsophila*, Sir George Watt tells us, are common in Sikkim. The natives (Lepchas) utilise the soft portions of the stem of one species, *Cyathea Brunoniana* of Clarke, for food. *Alsophila glauca* is, perhaps, the handsomest and largest Indian Tree-fern, but its stem never branches. *A. ornata*, the "dangpashin" of the Lepchas, is a small species not uncommon a little below Darjeeling, and its stem is frequently branched. This, therefore, may be the species represented at fig. 72.

than is known at present. The buds are almost completely safe, so long as they are well coated with lime and sulphur, for, although birds may try a few, they do not appreciate the flavour. But the difficulty is to make the stuff stick on the buds, which are much smoother than the branches. Two or three rainy days are sufficient, at least, if the rain be heavy, to wash enough of the stuff off to render the buds palatable to birds. A small quantity of linseed oil has been tried instead of soft soap in the wash, in the hope that it would make the stuff stick on the bushes better, but it proved less effectual. Another trial was with builders' size instead of soft soap, half a pound being used in 25 gallons; and in a third paraffin, $\frac{1}{4}$ pint to a gallon of the wash was used. As no rain has fallen since these experiments were made, their

results remain to be seen. But, so far as the slight rubbing of the coated branches with the fingers may be regarded as a test, neither size nor paraffin is any improvement upon soft soap.

Small trials of two other ingredients are to be made with a syringe, as it is feared that either would clog the spraying machines. These are gas tar and Portland cement, each in a highly diluted form. There is no doubt that cement would set the lime firmly on the bushes, but the danger is that the setting would take place in the spraying machine. Probably tar also would make the lime and sulphur stick on bushes well, while it might serve by itself; but the question is as to whether a spraying machine could ever be got clean after even tar-water had been used in it.

It may be that some waterproof substance would serve the purpose of preventing rain from washing the spray-stuff off the bushes, and, possibly, a chemist or a manufacturer of waterproof materials could suggest one which would dissolve or mix well enough in water to pass easily through a spraying nozzle. The work of spraying on a large scale is so arduous and expensive that it is a serious matter to have to do it two or three times in a season to protect buds from birds. On the other hand, if no protection is afforded where wild birds are numerous, as they are in nearly all parts of this country, the damage done is incalculable. Not only is the fruit crop of the season reduced to a great extent, but the branches stripped of buds are rendered barren for all future time, and require to be cut off at their bases; while buds which would form new or extension branches are eaten off, so that the bushes are deformed and stunted. A small area of Gooseberries, $\frac{1}{4}$ acre in extent, near my farm-buildings was almost ruined two years ago by birds, and it will never be worth much hereafter.

As to the birds that do the mischief, bullfinches and sparrows are commonly regarded as the worst offenders, but chaffinches, tits, and some other birds help in the work of destruction.

Up to the time of writing the attack of birds upon the buds of Plums has not begun. The trees are inspected nearly every day, however, in order that spraying may be started as soon as the slightest damage is noticed. Moreover, choice Plums and Pears in my private orchard have been sprayed already as a precaution, though they will probably have to be treated again hereafter. It would be interesting if fruit growers generally would observe and publish the dates upon which bud-eating starts among Gooseberries, Red and White Currants, Plums and Pears, respectively.

The winter spraying of Apple and Plum trees with caustic soda and caustic potash was pursued from the first season after the planting one until the wash described in the first part of this article, without the soft soap, was substituted last winter. It was substituted for the older spray-stuff in the hope that it would check scab in Apples and leaf-blight in Plums, and possibly kill the eggs of the Apple sucker, the aphid, and various other insects. The worst attacks of scab and aphid ever experienced followed, whereas not an Apple sucker was found in a plantation that swarmed with that pest in the preceding season. Whether this immunity was due to the application of the new spray-stuff or not cannot be decided. If the stuff did not kill aphid eggs, it seems hardly likely that it destroyed the eggs of Apple suckers. The operation is now due, and probably the new Woburn winter wash will be tried for Apples, as it kills scale eggs, and therefore may be expected to prove fatal to the less protected eggs of the aphid, the Apple sucker, and other pests, besides which it should be at least a partial preventive to scab. It consists of 15lb. of copper sulphate, 5lb. of quicklime, 20lb. of caustic soda, and 50 pints of paraffin to 100 gallons of water. The directions are to slake the

lime and make it into a milk, mixing the copper sulphate previously dissolved with it, then adding the paraffin, churning the mixture thoroughly, further adding the caustic soda previously dissolved, churning again, and making up to 100 gallons with water. The only hesitation as to the use of this mixture is in regard to its extreme strength, particularly in relation to the copper sulphate and the paraffin; but Mr. Spencer Pickering states that it is quite safe. For Plums the same wash as has been used for Gooseberries will be applied.

Two operations of similar character are in progress at the time of writing. One is that of carting small chalk on to a field not yet planted, and to be used for Potatoes; and the others is that of sowing ground chalk at the rate of one ton per acre in all fruit plantations. The small or waste chalk of lime works is given away to anyone who will cart it, and 10 tons per acre can be applied at simply the cost of carting it. Even if it has to be sent a few miles by rail to a station near the user, the expense of the quantity named is small, only a small charge being made for loading into trucks, while the rail-rate is low. Ground chalk is not commonly prepared, but has been supplied to meet a special order for a large quantity. The chalk as quarried has to be dried in a kiln before being ground as finely as lime is, and it is put into bags for transport. In a report of some experiments with it in Lancashire the cost at a local station was stated to be 6s. 6d. per ton; but to me the charge is 10s., including rail carriage and the free use of the bags. Even at that price it is less than half as much per ton as ground lime costs, and, although 1 $\frac{1}{2}$ tons of ground chalk are needed to be equivalent to one ton of quicklime, the former is the cheaper of the two, while the work of sowing it is very much less unpleasant.

As quicklime quickly becomes converted to carbonate of lime (or chalk) on exposure to the atmosphere, its only advantage over chalk is its greater fineness when slaked.

The good old practice of chalking land at wide intervals where the soil is deficient in lime has fallen sadly into disuse. Lime is needed for all crops, and especially for all kinds of fruit. *A Working Grower.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

R.H.S. COMMITTEE MEETINGS ON MARCH 5.—I sincerely trust that the council of the R.H.S. will never again make the blunder of letting the hall on one of the days it is required for its proper use, and so have to ask Fellows not to show. As one of those who worked and, in however small a degree, helped to pay for the provision of this building, I object to its use for any other purpose, when it is required for the use of the society, and I have no doubt that many other Fellows hold the same opinion. *George Paul.* (See p. 157.)

SOIL STERILISATION.—Respecting the "sterilisation of soil," I practised this method I think before the word was particularly applied to the soil. I believe I was the first or amongst the earliest that practised baking or frying their potting soil. *H. Cannell, Swanley.*

ABIES MAGNIFICA VAR. XANTHOCARPA.—I was very pleased to see the figures and description of this Fir in the *Gardeners' Chronicle* for February 28, as there is still a great deal of confusion in connection with these North American Abies. *A. nobilis* and *A. magnifica* especially are very often mixed up, and yet they are quite distinct. A loosely-worded description of one would apply almost equally to the other where there is only the leaf and general habit to go by. There is also a considerable amount of variation between individual plants of the same species, even when raised from the same batch of seeds. Here we have some three to four hundred plants of *A. nobilis*, varying in size from 2 feet to 6 feet, which have all been raised from seeds obtained from one old plant. All these

young plants show a certain variation in size and shape of leaf, some being thin in texture and closely set on the stems, while in others the leaves are stouter and more openly arranged. The rate of growth also varies considerably, the majority making the usual 6 inches or so that *A. nobilis* makes annually, while some make long leaders, and have a comparatively thin habit. The latter will make sizeable trees in a shorter time than the former, though they are not such handsome specimens in a young state. The amount of glaucousness is also variable, some being highly glaucous, and others almost entirely green, while there is practically every variation between the two extremes. The Douglas Fir (*Pseudotsuga Douglasii*) is another North American Conifer that shows a considerable amount of variation, but with this Fir the differences seem to run more in certain definite types than in individual variation. The typical plant is a fast-grower, making a large tree in a comparatively short time, and having a thin, open habit, which gives it a look of being overgrown and narrow in proportion to its height. Then there is a form which is sometimes met with under the varietal name of "*vera*," which is slower growing, of a more symmetrical habit, and has foliage of a grass-green colour. There is also a form that has occurred with us, though not in any great quantity, which resembles the type in general appearance, but has a dwarf habit, growing only about one-third as fast. It makes a very handsome, small specimen, but takes years to attain to any considerable size. As practically all the Douglas Firs grown in this country are raised from imported seed, I have often wondered whether the seeds have been collected at various altitudes. If so, it would account for these differences of growth, the strong-growing typical plant coming from the valleys, and the dwarfier forms from the hill-sides. The Colorado Douglas Fir (*P. D. var. glauca*) also varies in its habit and amount of glaucousness, and shape and size of leaf, but as this is a variety and is raised from seed, a certain amount of variation is to be expected, though I cannot remember one seedling that has reproduced the entirely green colour of the typical Douglas Fir. This Colorado form will never make a timber tree of any economical value in this country, in my opinion, as its rate of growth is slow, and it does not give one the idea of being a tree that will ever attain any great size. It is also more liable to be cut by spring frosts than the Douglas Fir, which happens, as far as I have been able to judge, through it commencing to grow earlier. As an ornamental tree, it is a very desirable plant, growing in soil that is not good enough for such Conifers as *A. concolor*, *A. nobilis*, *A. Nordmanniana*, &c. *J. Clark, Bagshot, Surrey.*

FROST AND SPRING-FLOWERING PLANTS.—Spring-flowering bedding plants in this district have suffered much from the recent severe frosts. Wallflowers which were strong and vigorous at planting time are in many cases little better than dried sticks. *Myosotis* has also been badly injured, and I am informed by older residents that these plants have not suffered so badly from frost for many years. Gardeners whose practice is to have a supply of plants in reserve, will now find the value of this system in being able to fill the vacancies in their beds, and thus make good the loss. Tulips, Crocuses, Daffodils and other bulbous plants promise well, and will doubtless compensate by their display for the disappointment caused by the failure of the other subjects. *A. B., Warrington.*

NARCISSUS "EMPRESS" NOT FLOWERING (see p. 148).—There are many causes which contribute to the non-flowering of bulbs. Abnormally late planted bulbs which are far too long in the dry state, would not be able to produce their root fibres in their proper season, with the result that an inferior bulb would result, in the spring, following upon inferior leaf growth. Consequently no flower is formed for the succeeding year. [The rudiments of the flower are formed in the spring, or not at all.] An excessively dry springtime contributes to the same thing. In the latter case established bulbs that are in a healthy condition rarely suffer. Excessive crowding of the bulbs in solid lumps and transplanting when in full leafage are other causes of non-flowering. Bulbs should never be transplanted when in green leaf if it can be avoided. *E. H. Jenkins, Hampton Hill.*

"**MIMOSA**."—I have always understood that the *Mimosa* of the florists' shops is *Acacia dealbata*, but the note of your correspondent *F. M.*, page 145, suggests that more than one species arrives under that name. The name of *Acacia Decaisniana* does not occur in any works of reference that I have at command, but unfortunately they do not include the *Index Kewensis*. It may be simply a local form of *Acacia dealbata*, as that species varies considerably in the glaucousness of its foliage as well as in other features when raised in quantity from seed. As the note of your correspondent suggests that he is at least doubtful about the matter, I shall be very pleased if you can enlighten me on the subject. *W. T.* [We suspect some error in the name, but have no means of rectifying it. It is not in the *Index Kewensis*.—*Ed.*]

ARAUCARIA IMBRICATA (see p. 100).—At Lota Lodge, Cork, the residence of A. F. Shyman-Crawford, Esq., one tree has sent up three finely-furnished shoots from its base, the tallest being something like 18 feet in height. I remember drawing the attention of Mr. T. Smith, of Newry, to these unusual growths, and he said it was the first case he had seen. The cause of these growths we have not been able to make out. The tree is in fairly good health, but the suckers are much more vigorous than the parent, and will in all probability supersede the old tree in time. *Andrew Pearson.*

LENTEN ROSES.—Mr. Archer-Hind's Lenten Roses (*Hellebores*) are now at their best, and are very beautiful, yet the flowers are found but in few gardens. Mr. Archer-Hind has been hybridising these plants for many years, and has succeeded in greatly improving the race, some of his seedlings being far in advance of the named Continental varieties. His first crosses were accidental, but some were so pretty that he was led to cross them by hand. He found that colour was introduced by the male pollen and shape by the female, and, by degrees, he improved the flowers wonderfully in size, shape, and colour, conquering the faults little by little. Not only was pollen taken from the best plants, but from the best flower upon the plant, natural defects being by this means eliminated. Now both star-shaped and cup-shaped flowers are produced, and colours ranging from the purest white, without any suspicion of green in the petals, to deepest maroon-red. Some of the whites and pale pinks are beautifully spotted in the interior with crimson-purple. Seedlings take three years to flower. Seed is sown as soon as ripe in fine soil on a damp border, and seedlings begin to show from December to February, the seedlings being transplanted in their second year. They do equally well in a sunny or shaded border if not too dry, and have a very pretty effect when planted out in numbers in open woods or along the base of lane-banks. If the flowers are used for the house, the stems must be split up to a length of about 3 inches, or they will droop at once, whereas if this precaution is taken they will last well for a week. Mice are very destructive in Mr. Archer-Hind's garden, and he informed me that he had lost over 100 buds of these *Hellebores* in one night through them. *S. W. Fitzherbert.*

CATS IN GARDENS.—I am happy to believe that few people will agree with your correspondent, Mr. A. J. Hartless (see p. 146), in his sweeping condemnation of cats. Surely at this season of the year in particular, when little demons in feather delight to demolish the fruit buds, it is the cat who is the gardener's friend and the birds' enemy. Likely enough the felines of Highgate distress the Waterlow Park gardeners by unauthorised attempts at gardening, but, even so, a cat is far too delightful an asset of city life to be thus thoughtlessly disparaged. *Jason.*

TRADE MEMORANDUM.

POSTAGE TO THE CONTINENT.—One of the leading German seedsmen writes us as follows:—"We experience a considerable loss every season through a great number of our British friends not bearing in mind that the postage to the Continent is 2½d. for every half-ounce. A little attention to this matter would save a good deal of annoyance and the unnecessary enrichment of the post-office at our expense." We willingly give publication to what seems to be a very justifiable complaint, owing to the thoughtlessness of correspondents.

SOCIETIES.

ROYAL HORTICULTURAL.

MARCH 5.—When the Council entered into an agreement with the SOUTH AFRICAN PRODUCTS EXHIBITION, it was stipulated that the Hall should be cleared on Monday, March 4, in order that the R.H.S. exhibition might be held as usual on Tuesday, and the South African exhibits were to be replaced afterwards. The South African Products Exhibition Committee subsequently found themselves unable to keep the agreement entered into, and, in consequence, a note from the R.H.S. secretary was printed in our last issue, stating that ordinary exhibits were not solicited on Tuesday, owing to lack of space. These circumstances were explained by Mr. W. Marshall (chairman) and by Mr. J. Hudson at the meeting of the Floral Committee, when the action of the Council came up for discussion. It was hoped, and thought, generally, that such circumstances would not be likely to occur again.

Nevertheless, room was found for more horticultural exhibits than in the circumstances were expected, and, in addition to a number of smaller groups of Orchids, a magnificent group of *Dendrobiums*, &c., from JEREMIAH COLMAN, Esq., found a place.

The ORCHID COMMITTEE recommended four First-Class Certificates and six Awards of Merit to novelties.

The FLORAL COMMITTEE recommended one First-Class Certificate and six Awards of Merit, and the Council made one Award of Merit to an exhibit that arrived late.

The FRUIT AND VEGETABLE COMMITTEE made no award to any novelty, but recommended a Silver Banksian Medal to J. T. CHARLESWORTH, Esq., Nutfield Court, Surrey (gr. Mr. T. W. Herbert), who showed two dozen dishes of Apples and Pears.

In the afternoon the Rev. Geo. Henslow delivered a lecture on "The True Darwinism."

Floral Committee.

Present: W. Marshall, Esq., chairman; and Messrs. George Paul, C. T. Drury, Geo. Nicholson, Jas. Walker, Jno. Green, T. W. Turner, Jas. Douglas, C. R. Fielder, R. W. Wallace, Jas. Hudson, Walter T. Ware, W. Howe, C. Blick, W. Bain, Chas. Dixon, H. J. Cutbush, Arthur Turner, W. Cuthbertson, W. P. Thomson, Chas. E. Pearson, R. C. Notcutt, J. W. Barr, Ed. Mawley, W. J. James, E. T. Cook, and R. Hooper Pearson.

Messrs. JAMES VEITCH & SONS, Ltd., King's Road, Chelsea, showed a number of charming little plants of *Azalea Hexe* X, in small 60-size pots, and intermingled with the yellow *Primula Kewensis* X—a most pleasing combination. At the back was a row of the large-flowered *Jasminum primulinum*, and at one end a batch of the sweet-scented *Boronia megastigma aurea*. We also noticed *Clianthus puniceus* and its white variety.

Mr. H. B. MAY displayed a small batch of seasonable greenhouse flowering plants, prominent among which were sprays of the scented-leaved *Pelargonium Clorinda*, some well-flowered *Clematis*, *Boronia megastigma*, and many beautiful Ferns.

Messrs. H. CANNELL & SONS, Swanley, Kent, staged some exceptionally fine plants of the large-flowering or giant type of *Star Primulas*, with flowers of remarkable size and colouring. They were arranged in rows of named varieties, and the colours included red, white, magenta, light blue or heliotrope, and ruby. One of the choicest was *W. Raphael*, a beautiful shade of red. *Attraction* (mauve) and *Mrs. H. Crooks* (white) are also worthy of mention. Messrs. CANNELL also displayed some very large trusses of flowers of *Pelargonium Clorinda*.

Rt. Hon. Lord ZOUCHÉ, Pulborough, Sussex (gr. Mr. Spillard), exhibited a dozen very large plants of the florist's *Cyclamen*, some being in 12-inch pots. They were very freely flowered, compact in habit, and showed general good culture. (Silver Banksian Medal.)

Mr. TAVERY, Loudwater Gardens, Rickmansworth, staged a batch of *Primula obconica*, of an improved strain, the flowers being very large and generally of the best form.

Messrs. HUGH LOW & CO., Bush Hill Park, Enfield, London, N., put up a small group of *Jasminum primulinum* and Carnations.

The beautiful deep-scarlet *Rose Richmond* was shown well by Mr. W. E. WALLACE, Eaton Bray Nurseries, Dunstable. This American variety is of exquisite form and is developed on very long stems, which are a valuable feature when the cut flowers are used for vases, &c.

Messrs. C. BROOKS & CO., Worting, Basingstoke, had inflorescences of the *Stellata* or *Star Primula* in many pretty shades of colours; one of a salmon-pink tint, named "Orange King," attracted considerable attention.

Mr. ROBERT SYDENHAM, Tenby Street, Birmingham, again displayed bowls of bulbous plants, grown in moss fibre, without drainage material. Lily of the Valley was doing exceedingly well under this system of culture.

Bulbous Irises were displayed by several hardy-plant growers. A very fine exhibit of these seasonable flowers was staged by Mr. F. HERBERT CHAPMAN, Guldeford Lodge, Rye. The collection was principally of varieties of *I. reticulata*. Other species were shown, including *I. Danfordiae*, *I. Krelagei*, &c.

Messrs. R. WALLACE & CO., Kilnfield Nurseries, Colchester, also showed species of bulbous Irises, as well as other pretty Alpine plants, such as *Narcissus monophyllus*, *Cyclamen ibericum lilacinum*, *Crocus Tommasinianus*, &c.

Messrs. BARR & SONS, King Street, Covent Garden, London, had many hardy spring flowers and an assortment of Daffodils of most types. We noticed the pretty *Tecophilæa cyanocrocus*, with its beautiful, blue petals tipped with gentian-blue.

Hardy flowers were also shown by Mr. G. REUTHE, Keston, Kent, and by the Misses HOPKINS, Barming, near Maidstone, Kent.

AWARDS.

FIRST-CLASS CERTIFICATE.

Cyrtomium falcatum Rochfordii.—The type is a well-known, brightly-coloured Fern that is capable of withstanding considerable ill-usage, owing to the substance of the fronds and pinnæ. The variety now shown has much divided margins to the pinnæ, which are moderately tessellated. Shown by Messrs. T. ROCHFORD & SONS.

AWARDS OF MERIT.

Iris "Aspasia".—This appears to be a variety of *I. reticulata*, obtained from crossing the type with one of its own varieties. In colour, the flowers are dark purple, the lamina of the falls having an orange-coloured stripe with a little whitish mottling on either side of the stripe.

I. "Melusine".—Of the same type as the preceding variety. Colour, light porcelain-blue, with orange-coloured stripe and white mottling on the lamina as in the other variety. Both varieties were shown by Mr. F. HERBERT CHAPMAN, Guldeford Lodge, Rye.

Freesia Chapmani.—This is a yellow-coloured *Freesia* with orange shades on the lower segments of the flower. It is rather more fragrant than *F. aurea*, but otherwise much resembles that plant. Shown by Mr. F. HERBERT CHAPMAN.

Lachenalia May Crosbie.—Several varieties of *Lachenalia* were received as cut flowers from Mr. F. W. MOORE, Glasnevin Botanic Gardens, Dublin, after the Floral Committee had risen. The council, in the circumstances, made an Award of Merit to the variety named above, which is a self-coloured yellow flower. Mr. MOORE has raised many excellent varieties of this plant, and "May Crosbie" did not appear to us superior to similarly-coloured varieties exhibited on previous occasions.

Primula stellata.—Messrs. H. CANNELL & SONS, Swanley, were awarded an Award of Merit for a strain of this type of the Chinese *Primula* (*P. sinensis*). The varieties shown had evidently been obtained from re-crossing the stellata type with the florists' varieties, and this has had the result of imparting increased substance and size to the flowers without destroying the free character of the inflorescence found in the ordinary type of "stellata." The varieties which composed the strain included *Mrs. H. Crooks*, and *White Clipper* (white), *Attraction* (mauve), *W. Raphael* (red), and *Masterpiece* (lavender).

Rhododendron (Azalea) amenum "Hexe".—This is a seedling variety of this well-known Indian *Azalea*, which has small, purple-coloured

flowers. "Hexe" has larger flowers, and their colour is bright red. It is not wholly descended from *R. amenum*, as this was crossed with another variety of *R. indicum*. The small plants exhibited by Messrs. JAS. VEITCH & SONS were very freely flowered.

Rose Richmond.—Cut blooms of this brightly-coloured crimson Rose were shown by Mr. W. E. WALLACE, Eaton Bray Nurseries, Dunstable. It is of American origin, and we have noticed specimens at the exhibition in winter for several seasons past. The flowers are favourites at the present time in Covent Garden Market. Those who appreciate the variety "Liberty" will like this one also. Its good qualities include an excellent and strong stalk, beautiful form as seen in bud, vivid colouring, and thick, smooth leaves that are likely to resist diseases.

Orchid Committee.

Present: J. Gurney Fowler, Esq. (in the chair); and Messrs. Jas. O'Brien (hon. sec.), Harry J. Veitch, De B. Crawshaw, Jeremiah Colman, W. Bolton, R. G. Thwaites, G. F. Moore, W. A. Bilney, J. Wilson Potter, Frederick J. Hanbury, W. Cobb, H. Little, W. Boxall, A. A. McBean, Arthur Dye, H. G. Alexander, W. H. White, H. A. Tracy, T. W. Bond, and H. Ballantine.

Notwithstanding the announcement that the hall would be occupied by the South African Exhibition, the Orchids were not to be denied, and room was made for a goodly quantity of them.

JEREMIAH COLMAN, Esq., Gatton Park (gr. Mr. W. P. Bound), took the lead with a grand group facing the entrance, and which was largely composed of the fine *Dendrobiums* and other hybrids raised at Gatton Park. The group, which was artistically arranged, had for a centre, high up at the back, a fine lot of *Calanthes*, sending their arching sprays all around. At intervals, sections of *Dendrobiums* were elevated above the body of the group, and at each end were slender plants of *Epidendrum Boundii* bearing a profusion of orange and scarlet heads of bloom. At one end were the Gatton hybrids of *Spathoglottis*, one of which secured an Award of Merit. Among the varieties of *Dendrobium nobile* were fifteen distinct named sorts, the most attractive of which, and the most delicately-tinted, appeared to be *D. nobile Colmanianum*, a clear white flower, with light violet centre. Among the hybrids were a great variety of fine varieties of the *D. rubens*, and *D. splendidissimum grandiflorum* sections, as well as new kinds flowering for the first time. The rare yellow species *D. signatum* was represented by a specimen with four flowering growths, and near it were some of the yellow *Dendrobiums* derived from *D. signatum*. Other specially noteworthy subjects were a good selection of *Cattleya Trianae*, *Cymbidium grandiflorum*, with fine spikes; the new *Cœlogyne Colmanii*, recently illustrated in the *Gardeners' Chronicle*; a good selection of *Cypripediums*, *Odontoglossums*, &c.

Messrs. CHARLESWORTH & Co., Heaton, Bradford, staged a small but select group, in which the principal plants were *Odontoglossum Elaine*, var. Golden Gem, an elegant flower with lemon-yellow ground colour evenly spotted with chocolate-purple; *O. Ossulstonii*, of perfect shape and fine marking; a very distinct, garden-raised *O. Adrianae*, with a branched spike of very pretty, darkly-blotched flowers; an excellent-spotted *Odontoglossum crispum*, and a few examples of the white type; and, among other hybrids, the new *Lælio-Cattleya Sheila* (*Cattleya Percivaliana alba* × *Lælia præstans alba*), a nice, pure white flower with orange disc to the lip. (Silver Banksian Medal.)

Canon The Hon. K. F. GIBBS, Aldenham Vicarage, Watford (gr. Mr. Lazzall), was awarded a Silver Flora Medal for six specimens of *Cœlogyne cristata*. The plants were fine examples of good cultivation, and Mr. Lazzall was voted a Cultural Commendation.

Major G. L. HOLFORD, C.I.E., C.V.O., Westnabirt, Tetbury (gr. Mr. H. G. Alexander), sent a very interesting selection of fine varieties for several of the best of which see Awards. Among them were *Cymbidium insigne*, Westnabirt variety, with two fine spikes, the one of fourteen, and the other of five flowers; a splendid specimen of the yellow *Dendrobium Ophir*; *D. melanodiscus* "Radiance," of good shape

and colour; *Sophræ-Lælia Psyche*, with eighteen bright, reddish, scarlet flowers. (Cultural Commendation.)

J. BRADSHAW, Esq., The Grange, Southgate (gr. Mr. Whitelegge), showed the noble *Cattleya Trianae* The Premier, which had previously secured the First Diploma, and now gained a First-Class Certificate.

Messrs. JAS. CYPHER & SON, Cheltenham, arranged a very effective group of rare and showy Orchids, in the centre being *Odontoglossum loochristense* "Empress Frederick," a splendid flower, with large and broad segments of a clear yellow, heavily blotched with red-brown, the white ground colour showing through at the bases of the petals and on the lip. Mr. Cypher's speciality of *Dendrobiums* were well represented and in their usual vigorous condition. (Silver Banksian Medal.)

Messrs. HUGH LOW & Co., Enfield, staged a group in which were several excellent forms of their famous strain of *Cattleya Trianae*, good *C. Percivaliana*, with one of the new *C. Percivaliana Little Gem*, the immature flower of which was nearly white with a yellow disc. (Silver Banksian Medal.)

Messrs. ARMSTRONG & BROWN, Tunbridge Wells, staged a good selection of hybrid *Cypripediums*, including *C. Maudiae* with three flowers; *C. Harrisianum albens*, *C. Fascinator magnificum*, *C. aureum Hyeatum*, *C. Lord Derby*, &c.; a white petalled form of *Dendrobium superbum*, *D. nobile virginale*, and *Cymbidium Woodhamsianum* (*Lowianum* × *eburneo-Lowio-eburneo*), like an enlarged very yellow-tinted *C. Lowianum*.

FRANCIS WELLESLEY, Esq., Westfield, Woking (gr. Mr. Hopkins), sent a fine plant of *Cypripedium* "Monsieur de Curte" Westfield variety, with fine flat dorsal sepal blotched with nearly black spots, the broad white margin having a ray of small purple spots. The petals and lip are honey-yellow, tinged with red-brown. It has the dorsal sepal much better developed than in other forms, and resembling, in many respects, a good *C. Euryades*.

GURNEY WILSON, Esq., Glenthorne, Haywards Heath (gr. Mr. Hill), showed *Odontoglossum crispum rotundum*, with one newly-opened flower which disclosed a remarkably beautifully blotched form, with circular shape and almost equal broadly ovate sepals and petals. The latent purple colour in the segments so prized by collectors of this favourite class was well indicated and gave promise of yet greater beauty when matured. It was of Mr. John Carder's collection.

J. GURNEY FOWLER, Esq., Glebelands, South Woodford, sent a fine form of *Cymbidium insigne* (see Awards) and a species imported with it, resembling *C. Wilsoni*, but said to be *C. Schröderianum*.

F. W. MOORE, Esq., Curator, Royal Botanic Gardens, Glasnevin, Dublin, sent two magnificent spikes of *Cymbidium grandiflorum*, Glasnevin variety, which had previously secured a First-Class Certificate.

AWARDS.

FIRST-CLASS CERTIFICATE.

Cymbidium insigne, *Glebelands variety*, from J. GURNEY FOWLER, Esq., Glebelands, South Woodford (gr. Mr. J. Davis). A magnificent form, with flowers much larger and broader in all their parts than other forms. Flowers silver white, with a slight blush shade and rose-purple spotting on the lip and bases of the petals.

Lycaste Ballie, *South Lodge variety*, from F. DUCANE GODMAN, Esq., South Lodge, Horsham. A very richly-coloured form with rose-red sepals and petals and ruby-crimson lip. The finely-grown plant had several large blooms.

Odontoglossum crispum Mossia, from J. S. MOSS, Esq., Wintershall Hall, Bishop's Waltham (gr. Mr. Kench). A very handsome variety, very distinct from others previously shown. The large, broad-petalled flowers have all the segments fringed, and of a silver white slightly shaded with rose, and blotched over the greater part with evenly distributed reddish-purple blotches.

Cattleya Trianae The Premier, from J. BRADSHAW, Esq., The Grange, Southgate (gr. Mr. Whitelegge). In size, shape and effective colouring, one of the best yet seen, and a model flower. The whole flower is perfectly filled in,

all the segments overlapping, and the crimped petals as broad as long. Sepals and petals silver-white, delicately tinged with rose-pink. Lip disc orange, with a broad crimson-purple blotch in front. The Grange collection is famous for fine forms of *C. Trianae*, and this, which has previously taken First Diploma, is considered by Mr. BRADSHAW the best of its class.

AWARD OF MERIT.

Brasso-Cattleya H. G. Alexander (*Cattleya citrina* × *Brassavola Digbyana*), from Major G. L. HOLFORD, C.I.E., C.V.O. (gr. Mr. H. G. Alexander). A remarkable hybrid between very diverse parents. The habit of the plant is erect, the broad pseudo-bulbs compressed, and two-edged, and the dark-green leaves fleshy. The flower, which displays a tendency to be pendent, is on a long, twisted ovary, the fleshy sepals and thinner petals projected forward and pale-yellowish green in colour. The lip, which is fringed on the whole margin, is green at the base, changing to primrose-yellow in front.

Odontoglossum mirum Lady Howick (*Wilckeanum* × *crispum Calypso*), from Major G. L. HOLFORD. A very pretty hybrid, resembling a good blotched *O. crispum*, and with labellum more like *O. Pescatorei*, but larger. Sepals and petals French-white, with large chocolate-purple blotches.

Cypripedium vill-exul (*villosum* × *exul*), from Major G. L. HOLFORD. A great improvement on *C. exul*, which it closely resembles in colour, the flowers being larger.

Spathoglottis Colmanii aureum, from JEREMIAH COLMAN, Esq., Gatton Park (gr. Mr. W. P. Bound). Flowers large, bright yellow, with a small ruby-red mark on the lip.

Cypripedium Dicksonianum (*villosum aureum* × *Euryades*), from FRANCIS WELLESLEY, Esq., Westfield, Woking (gr. Mr. Hopkins). A very brightly-coloured flower, the dorsal sepal being of a rosy-crimson deepening to ruby-crimson at the base, and with a broad snow-white band on the upper part. Petals and lip honey-yellow, tinged with mahogany-red, the whole surface being glossy.

Cypripedium Mrs. Francis Wellesley (*Sanderianum* × *Gouvierianum*), from FRANCIS WELLESLEY, Esq., Westfield, Woking. A fine hybrid, beautiful in leaf and flower, the latter partaking of the dark tropical beauty of *C. Sanderianum*, with the form and rosy tints of the other parent blended. The fine dorsal sepal has a greenish base, the upper part tinged with rose, and the whole bearing closely-arranged irregular lines of dark chocolate colour. The extended petals are similar in colour and bearing blackish-warted spots, the marginal ones ciliate. Lip large, reddish-rose on the face.

THE EXHIBITION OF SOUTH AFRICAN PRODUCTS.

which continues on view until to-morrow week (16th inst.), is naturally of relatively little importance horticulturally, and, apart from the minerals, with which South Africa is so largely interested, the exhibits are chiefly concerned with agriculture. Thus on all sides are seen picked samples of cereals, tobacco, cotton, tea, coffee, timber, wool, preserves, jams, jellies, bottled fruits, &c.; wines, spirits, brandy, lemons, oranges, citrons, medicinal herbs, tanning barks, fibres, pineapples, rubber, gums, honey, fodder, oil-producing seeds, and a host of other things from Cape Colony, Natal, the Transvaal, Rhodesia, and the Orange River Colony. The few fresh fruits that are on view are principally Apples, Pears, Plums, and Pineapples; the last-named fruits are very small, from Natal, but of agreeable flavour. Samples of tea appear on several stands, and the growth of this important industry nearer home may have a marked effect on the price of this important commodity. In the matter of wines, South Africa appears able, judged by the extensive samples displayed, to supply the home market with almost all the brands required, including brandies, liqueurs, and other spirits. The oldest wine growers and distillers in these colonies are Messrs. J. Sedgwick & Co., whose business was founded at Cape Town as far back as 1859 by Captain James Sedgwick, formerly in the Honble. East India Company's service, and grew steadily until, having outgrown their accommodation, the firm in 1881

added to their already commodious buildings—magnificent stores, where are housed in various stages of maturation about 750,000 gallons of wines and other liquors. Bats' guano, vulture-excrement, and ant-hill soil appear strange fertilisers to us who rely on nitrate of soda, guano, &c., but no doubt they are equally rich in manurial properties. The ancient native hoe appears a clumsy tool, but it was in use before the advent of the white man to these lands. It was made from smelted iron-stone by the native blacksmith, but is now largely superseded by our modern tool. The native blanket, made from the inner bark of some tree, does not appear so inviting as our woollen equivalent, nor does the native pillow, which is merely a wooden settle on two short legs, and hollowed at the top for the neck, appear to be capable of affording comfort. We should not care to exchange our chop or steak for a strip of the mummified springbok, nor does dried locust appeal to us as being especially inviting, although we were informed that this is one of the native's greatest delicacies. The native tobacco appeared to be more suitable for building purposes than for vaporising, and a new use was discovered for Agave leaves when we were told that they form the principal ingredient of native snuff. What appeared to be tubers of *Stachys tuberosa*, on closer examination were found to be "plugs" of raw rubber, that unwound like gigantic spider webs. This important vegetable product was also seen in balls, known as "nigger heads," which, by some mysterious means, often conceal a heavy stone. As rubber is bought from the natives by weight, a cautious dealer will always cut open the "nigger head" to see that he is not purchasing road-mending material. Raw rubber is also exhibited in many other forms. The new Calabash pipes were displayed by more than one firm, and these must be a profitable industry, judging by the prices asked for specimens at the show. An interesting little exhibit was of pieces of granite, with tiny yellow and red lichens. These were collected near the late Cecil Rhodes' grave on the Matoppos Hills, of which some very fine photographs were on view. The show is bristling with interest, and is especially valuable to the intending settler, and now that tranquillity prevails in these colonies, we may look to an era of prosperity which needs but the hand of the labourer to develop and reap the riches with which these lands are naturally endowed.

Messrs. STURTON & SONS, Reading, display an assortment of flower and vegetable seeds suitable for cultivation in South Africa, and an ornamental clock filled with wax models of similar vegetables.

HORTICULTURAL CLUB.

"HIMALAYAN SCENERY AND VEGETATION."

MARCH 5.—The usual monthly dinner of this club was held on the above date at the Hotel Windsor, Mr. Harry J. Veitch occupying the chair and a good number of members and friends attended to hear the promised lecture on the above subject by Sir George Watt, K.C.S.I. Sir George illustrated his subject by a large number of lantern slides prepared from photographs taken by himself in the course of his travels. The introductory slide was a map of India, showing how the great range of the Himalayas formed an immense wall to the north of the huge peninsula, which wall at both ends radiated out into a fan-like extension of ranges, the whole constituting a practically insurmountable defensive barrier and exercised in addition a remarkable effect upon the climatal conditions of the whole of the southern area of India by deflecting the trade winds, creating the beneficial monsoons and in this way redeeming the whole country from the desert conditions which would otherwise prevail. Curiously, too, the whole of the great river system rising from the large area of perpetual snow pervading the higher regions of these mountains, even that part which originates on the northern flanks, finds its way southwards and permeates the land in all directions to the greater amelioration of climatal conditions. The vast accumulation of snow and ice which in some of the views, with tropical vegetation in the foreground, could be seen like a long line of ragged white cloud in the dim distance far above the horizon, distributes its cooling influence far and wide and constitutes an inex-

haustible source of supply to the great rivers to which it gives birth, their season of flood occurring in the hottest season of the year owing to increased melting of the snows. In this connection Sir George Watt mentioned that amid these snows and ice, hundreds of feet thick, it was only practicable to travel in the early morning or in the evening, the intense heat of the sun's rays at midday, perhaps 140° Fahr. or more, being unbearable, a heat, moreover, which had the curious result, that any water resulting from consequent melting of ice or snow was instantly evaporated, and hence there was no sign at all of thawing. The grandeur of the scenery amid the loftiest peaks was indescribable as it was also in the mighty gorges cut by the rivers which traversed the range on their way southwards. Huge perpendicular cliffs, thousands of feet in height, largely consisting of white limestone, soared on either side of a narrow channel through which the fierce flood tore its impetuous way to the freedom of the lower-lying plains. In some places there was practicable a rude and primitive navigation by means of inflated bullocks' skins of very comical appearance. A number of slides afforded delightful glimpses of tropical conditions and also the modified ones prevailing in Sikkim, Simla, and Kashmir, giving a vivid idea of the difference induced in climate under the tropics, by varied elevation and environment, some parts of the country having a climate like our own, others being truly tropical, while at the other end of the scale we find truly Arctic conditions, such as mighty glaciers, avalanches, and so on. Naturally Sir George Watt's descriptions included the vegetation, some of the apparent pasture land consisting of dense masses of Alpine flowers and many of the hill flanks appearing solid with Rhododendrons of many species and all the hues of the rainbow. At one spot high up the mountains, where the only vegetation were the lichens encrusting the rocks, it was possible to look down and see, as it were, the different climatal layers of vegetation, Arctic, temperate, subtropical and tropical, culminating in the Bananas, Palm trees, &c., of the warmest regions, the whole embraced in one comprehensive view.

The Vale of Kashmir would appear to be a terrestrial paradise, and is peculiarly interesting as regards its floating gardens, sometimes an acre or more in extent, which are constructed on the Kashmir Lake, of boughs and other material woven together and covered with soil, and yielding fine crops of various kinds. In all some 100 or more slides were shown and rapidly and graphically described, to the great pleasure of the members.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

FEBRUARY 7.—Committee present: E. Ashworth, Esq., chairman; and Messrs. Thorp, Warburton, H. H. Smith, P. Smith, Rogers, Sander, Ward, Keeling, Cypher, Ashton, R. Ashworth, Thompson, Parker, Upjohn, P. Weathers (Hon. Sec.)

There was a capital exhibition, several choice groups being shown.

A. WARBURTON, Esq., Haslingden, staged a pleasing group of *Odontoglossums*, &c., and was awarded a Silver Medal.

W. THOMPSON, Esq., Stone, also received a Silver Medal for a group.

Messrs. ARMSTRONG & BROWN, Tunbridge Wells, Kent, made their first appearance at Manchester as exhibitors, having a splendid set of *Cypripediums*, for which they were granted a Silver Medal.

Messrs. CYPHER & SONS, Cheltenham, staged a showy group of Orchids, for which a Silver Medal was awarded.

Messrs. SHACKLETON, Bradford, and J. W. MOORE, Ltd., of Leeds, obtained Bronze Medals for groups.

A Cultural Certificate was awarded to O. O. WRIGLEY, Esq., for a collection of *Lycastes* (gr. Mr. Rogers).

Votes of thanks were awarded to Messrs. CHARLESWORTH, J. E. SADLER, KEELING & SONS, and E. ROGERSON, Esq., for contributions to the meeting.

AWARDS.

A First-Class Certificate was granted to *Cypripedium* insigne var. *McNabiana*. First-Class

Certificate and Awards of Merit to *Cypripedium* × *Diadem* var. "Grand Model," shown by Dr. HODGKINSON. C. × *nitens* var. *Queen of the Yellows*, C. *Dowlerii* var. *Virginian* "Orchid-hurst var.," C. × *Titian*, C. × *Juno Drowett's* var., these five from Messrs. ARMSTRONG & BROWN. C. × *Lathamianum* var. *Thompsoni*, and C. × *Rupert*, shown by Mr. W. THOMPSON. C. × *Dowlerii* var. *punctatum*, from Messrs. CYPHER & SONS; and *Cattleya* × *Enid* var. *superba*, shown by Messrs. CHARLESWORTH & CO.

FEBRUARY 21.—A meeting was also held on this date, when Silver Medals were awarded to Messrs. A. WARBURTON, Messrs. CYPHER & SONS, and H. J. BROMILOW, and Bronze Medals to Messrs. KEELING & SONS, and Mr. J. E. SADLER for groups of plants.

A First-Class Certificate was given to A. WARBURTON, Esq., for *Odontoglossum* × *Lambeauianum* Warburton's var., and Awards of Merit to *Cypripedium* × *Picus* (parentage unknown), and *Odontoglossum* × *Lambeauianum* Ashworth's var., both shown by R. ASHWORTH, Esq.; *Lycaste Skinnerii* var. "King of Spain," exhibited by J. ROBSON, Esq.; *Dendrobium* × *Wiganæ*, var. "Snowflake," shown by G. W. JESSOP, Esq.; *Odontoglossum crispum* var. "Samuel Gratrix," *Cypripedium* × *Archimedes* var. "Prince Eddie," the two last-named shown by S. GRATRICK, Esq.; and *Cattleya Trianae* var. "Edgar Knight," exhibited by Messrs. STANLEY & CO. P. W.

LEEDS PROFESSIONAL GARDENERS.

FEBRUARY 13.—The annual dinner of the Professional Gardeners' Lodge, a society which was instituted as the Professional Gardeners' Friendly Benefit Society in 1867, but which is now affiliated as a neutral lodge of the Grand United Order of Oddfellows, took place at the Green Dragon Hotel, Leeds, on the above date. There was a large attendance of the members. On January 1, 1867, the Professional Gardeners met and paid their first contributions, the records showing that 77 members paid on that night. By 1871 this number was increased to 120, and from that time to the present the number has fluctuated between 115 and 145. Of the 77 original members, all but 12 have passed away. During the 40 years upwards of £2,200 has been paid out to the members during sickness, and upwards of £900 in funeral allowances, in addition to which £1,424 has been saved and invested at interest to meet future contingencies, the interest from which is now a very valuable asset. Honorary members, during 40 years have contributed upwards of £600 to the funds. The total income for the year has been £176 2s. 9d. and the total expenditure £100 7s. 4d., which leaves a credit balance of £75 15s. 5d.

Obituary.

DEATH OF A FAMOUS ORCHIDIST.—Sir Frederick Wigan, Bart., died suddenly on March 2 whilst going to record his vote in the election for the London County Council. Sir Frederick's collection of Orchids at Clare Lawn, East Sheen, is a remarkable one, and the *Phalænopsis* are equal, if not superior, to any in the British Isles. They were formerly under the charge of Mr. Want, now head gardener at Clare Lawn, and for the past seventeen years have been cultivated by Mr. W. H. Young, who has written our "Orchid Houses" Calendar in several previous years. Deceased was a liberal and kind employer. He supported the Royal Horticultural Society always, and was a vice-president at the time of his death. His son, Mr. A. L. Wigan, is a member of the present council. The baronetcy will devolve upon the eldest son, Mr. F. W. Wigan.

JOHN MCHATTIE.—We regret to hear of the death of John McHattie, aged 18 years, the only child of Mr. J. W. McHattie, Superintendent of the Parks and Open Spaces in the City of Edinburgh. Deceased was learning the nursery and seed business under the firm of Messrs. Thomas Methven and Sons, Edinburgh.

MARKETS.

COVENT GARDEN, March 6.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—Ed.]

— French, Cos, per dozen	8 0-50				

REMARKS.—A good demand exists for English hot-house Grapes, but supplies are short. There has been a considerable advance in the prices of French Salads during the past week. American barrels of Apples are cheaper. Cape fruit is selling well. P. L., Covent Garden, Wednesday, March 6, 1907.

POTATOES.

Bedfords, 65s. to 80s.; Blacklands, 65s. to 75s.; Lincolns, 70s. to 95s.; Yorks, 80s. to 100s.; Dunbars, 90s. to 120s.; Teneriffe, 10s. to 12s. cwt. Trade is about normal for the time of year. W. J. C. & S., Covent Garden, March 6, 1907.

COVENT GARDEN FLOWER MARKET.

There has been no improvement in trade during the past week, and good flowering plants are more plentiful with a less demand. Azalea indica in all its varieties are so cheap that there can be little profit for the grower, who imports the plants for forcing from Belgium. Dutch Hyacinths are also over-plentiful, but the trade in them is perhaps not quite so bad as it was a few years ago, when several growers were unable to meet their liabilities through the losses sustained on Dutch bulbs. Daffodils are now a leading feature, and one grower informed me that he has done well with these plants this season. Genistas are now in better condition, and Cinerarias are also considerably better in quality than they were, but as supplies are increasing the prices are falling. Cyclamen are more numerous, but many are of indifferent quality. I mention this to remind florists who may be ordering from the provinces to be careful to specify for best plants. There is now much variation in the quality of all market plants, and the standard is not so high generally as when fewer were sent to market. Erica Wilmoreana is one of the best flowering plants seen, and E. persoluta alba is still very good. Supplies of Begonia Gloire de Lorraine hold out well. Lily of the Valley in pots is remarkably fine. Best quality plants of Marguerites are plentiful. Some of the samples of Spiraea japonica seen are good, but there are some in the market which are a disgrace to the grower. Solanums are now of poor

quality. Ferns are now a better supply, but many have soft, immature spring foliage. The small plants are very good. Palms vary but little, except that the prices for the larger specimens are lower.

CUT FLOWERS.

Supplies are very abundant, and there is a further depreciation in prices all round. Tulips are a leading feature, and of these flowers some remarkably fine double varieties are seen. Prices generally for Tulips are down to about half what they were a month ago. Roses vary greatly. Special blooms on long stems keep up a demand, but ordinary quality are not much wanted. Cathartians also vary. Second quality blooms have to be offered at low prices to clear. Enchantress is rather overdone just now. Best "Whites" and "Scarlets" are most in demand. Daffodils of the better sorts are now seen, the principal varieties are Emperor, Horsfield, and Golden Spur. Sir Watkin is also a general favorite. Prices for Callas have fallen considerably, and it is surprising the qualities left unsold at closing time. Lilium longiflorum of best quality are not over abundant, and many are seen with imperfect flowers. All flowers with short stems, such as Azaleas, Eucharis, Camellias, &c., are well supplied, but the demand is not great. Imported flowers are arriving in large quantities. Parma Violets could be bought this morning at from 2s. to 3s. per large bunch, and the "Blues" are also much cheaper. The Paper White Narcissus and Soleil d'Or are cheap, but not of such good quality as usual. Mimosa is now at its best. Ranunculus in various colours are very pretty. The Pink Anemones are not yet quite so fine as we generally see them. A. H., Covent Garden, Wednesday, March 6, 1907.

THE WEATHER.

THE WEATHER IN WEST HERTS.

Week ending March 6. Warm days and cold nights. The temperature was mostly high during the daytime and low at night. On the warmest day the highest reading in the thermometer screen was 52 degrees, and on the coldest night the exposed thermometer registered 13 degrees of frost. The temperature of the ground both at 1 and 2 feet deep is now about seasonable. Rain fell on one day, but to the depth of less than a quarter of an inch. This small quantity, however, proved sufficient to restart the bare soil gauge. Previously there had been no measurable percolation through either of the soil gauges for over a week. The sun shone on an average for four hours a day, or for an hour a day longer than is usual at this season. Calms and light airs alone prevailed during the week. The mean amount of moisture in the air at three o'clock in the afternoon fell short of a seasonable quantity for that hour by 7 per cent. Narcissus minimus came into flower in my rockwork on the 2nd, which is 17 days later than its average date in the same spot for the previous nine years, and later than in any of those years.

FEBRUARY.

A cold, dry, and exceptionally sunny month. This was the coldest February for five years. The days were, as a rule, less unseasonably cold than the nights. During the first half of the month there were no unseasonably warm days or nights, and yet it was during the last week that the lowest reading was registered by the exposed thermometer, viz., 18 degrees of frost, by no means an exceptionally low reading for the time of year. Rain, hail, snow or sleet fell on 16 days, to the total depth of 1 1/2 inch, which is about half an inch short of the February average. At no time was the ground completely covered with snow. The sun shone on an average for three hours a day, or for 42 minutes a day longer than is usual. In the last 21 years there have been only four Februaries as sunny. The wind were, as a rule, light, but on one day there occurred a westerly gale, during which, in the windiest hour, the mean velocity reached 26 miles. The mean amount of moisture in the air at 3 p.m. was one per cent. below the February average for that hour.

THE WINTER OF 1906-7.

A very cold and remarkably sunny winter. It is now 12 years since the mean temperature of any winter was as low as that of 1906-7. December and February were cold months, but during the greater part of January high temperatures prevailed both during the daytime and at night. The highest temperature of the season was in no way remarkable, but on one night in December a thermometer exposed on the snow registered 30 degrees of frost—or the lowest reading in any December for 16 years. The total rainfall fell short of the average by about 1 1/2 inch. December was wet, but both January and February were dry months. The heaviest fall of snow occurred on the 29th of December, when the snow lay to a depth of 3 inches. The sun shone on an average for 3 hours 14 minutes a day, or for 35 minutes a day longer than is usual. In the last 21 years there have been only two other winters as sunny.

OUR UNDERGROUND WATER SUPPLY.

Since the winter half of the drainage year began in October the total rainfall has been 15 inches, or 2 inches in excess of the average for the same five months—equivalent to an excess in rainfall on each acre in this district of 45,240 gallons. At the same time last year there was a deficiency of 8,390 gallons per acre. E. M., Berkhamsted, March 6th, 1907.

NEW INVENTION.

A WEED EXTRACTOR.

Mr. C. E. West, horticultural sundriesman, 11, Norfolk Road, Higham Hill, sends a patent tool for extracting weeds from lawns. It consists of a handle shod with a hollow ferrule that is suspended on its edge, much like a cheese-taster. This is pressed over the weed, and by a twist the weed and soil are removed as a core. The implement can be obtained from all seedsmen.

ENQUIRIES AND REPLIES.

BIRD LIME.—I have heard of a kind of bird lime far exceeding any other in viscosity. I should much like to know where it is to be had; it is most useful for catching the detestable sparrow. E. F.

ANSWERS TO CORRESPONDENTS.

* * * The Editor will be glad to receive, for consideration, large photographs of horticultural subjects, suitable for forming Supplementary Illustrations to this Journal.

AGRICULTURAL RESEARCH ASSOCIATION: H. P. The research station of this association is at Glasterberry, Milltimber, near Aberdeen. The hon. secretaries are Messrs. Ranald R. Macdonald, Factor, Cluny Estates, and John Milne, Dyce.

APPLE SHOOT: A. L. G. Kindly forward a branch with more eggs upon it than the one you sent, and we will submit it to our entomological expert.

BEECH TREES WITH SCALE: E. T. The boring of holes and insertion of sulphur would do no good. Spraying with the kerosene (paraffin) emulsion would be beneficial, especially if its use could be attended with a brushing of the stems with a stiff brush. Cyaniding with hydrocyanic acid gas, if it could be made applicable, would be even more effective.

BEGONIA FLOWER: D. In our figure last week the only female flower depicted was a terminal flower. The point is this, that female flowers on this plant are usually terminal, which is very different to saying that all terminal flowers are female—as a matter of fact, they are often male.

BOOKS: A. G. P. There are scores of books on botany, and as you do not state your requirements we do not know how to advise you. Presuming you require elementary books we may mention *Scott's Introduction to Structural Botany*, 2 vols., to be had from our publishing-department. As an introduction to the natural families and to the knowledge of wild plants, *Dr. Watt's School Flora* (Rivington's) is very suitable.

CABBAGE-LEAF SPOT: R. V. & S. The conidial stage of *Sphaerella brassicicola* (see Cooke's *Pests of Cultivated Plants*, p. 82, pl. vii., fig. 100). It has been unusually common and destructive in the past few weeks, rendering crops useless. You had better root up all diseased plants and burn them, disinfect the soil, and plant no Cruciferae on the spot for at least two years. Syringe any other plants not yet affected with diluted Bordeaux mixture, so as to prevent infection. It seems to be gaining ground as a pest. The mature spores are produced in the dead leaves, after resting on the ground. Hence all fallen leaves should be carefully collected and burnt.

CAMELLIAS: H. R. We cannot undertake to name varieties of Camellia. Send them to some specialist grower.

CAUSTIC SODA SPRAY: W. G. G. Caustic soda 70 per cent. 1 lb., carbonate of potash 80 per cent. 1 lb., soft soap 1 lb., water 10 gallons. Dissolve the soda and potash in water, and dissolve the soft soap in a further quantity of hot water. Then pour the soapy water into the rest, making it up to 10 gallons with clear water. See also Mr. Spencer Pickering's article on p. 98.

CHAMPION GRAPE CLASS AT SHREWSBURY: F. W. P. It is necessary for an exhibitor to win the cup three times before it becomes his property, but the wins need not be in successive years. It may be pointed out that the Shropshire Horticultural Society regards the proprietor as the exhibitor, otherwise the cup would already be the property of Mr. W. Shingler, who has won it four times, twice for the late Lord Hastings and twice for the present lord. We hope your dispute is now settled amicably.

CORRECTION: *Odontoglossum Watianum princeps*. By a misunderstanding the note accompanying the illustration in the issue for March 2, p. 135, stated that this was a home-raised hybrid. Messrs. Sander informs us that it was imported with *Odontoglossum Harryanum*.

CROCUS FAILING: B. L. We believe the corms will develop properly after another season, or perhaps two. There is no disease apparent.

CYPRIPEDIUM AND PAPHIOPEDILUM: M. L. L. Yes, the Kew authorities have adopted the name *Paphiopedilum* to indicate a genus distinct from the old *Cypripedium*. The distinctions are that the leaves are rolled (convolute) in *Cypripedium*, the sepals are valvate, i.e., do not overlap in the bud, and if you cut across the fruit or young seed-vessels you will find there is but one cavity, and the ovules, or young seeds, are attached to the walls of the ovary. In *Paphiopedilum* the leaves are folded, not rolled, the sepals overlap in the bud and the seed-vessel is mostly 1-celled, or partially 8-celled, owing to the infolding of the placentas bearing the ovules. It is a matter of opinion which name you adopt. For ourselves we think for cultural purposes it is well to keep to the old genus *Cypripedium*, and adopt the other names to indicate sections or subdivisions of it.

ELM TREE: Scotsman. As you would scarcely wish to retain the tree after it had been killed, would it not be better to fell it at once? If not, it would be an easy matter to kill the roots with carbolic or other strong acid.

GARDENER'S SALARY: H. S. H. We agree with you that the sum offered is inadequate, but as the supply is larger than the demand, and unless gardeners co-operate more readily to improve their position, we fear there is little chance of improvement. The sum you mention might be sufficient for a casual labourer, but not for a trained gardener in a responsible position.

GREENHOUSE AND STOVE PLANTS: F. E. P. We would rather not express a definite opinion on this matter. Logically, a greenhouse plant would be one grown in a greenhouse, and it might perhaps be sufficient for the exhibitor to show that his plants had been cultivated in such a house. But it must be remembered that a species may be a greenhouse plant in one locality, and at one season, but an out-of-doors plants in another locality, or at another season. Until the judges have determined in a particular case whether *Lily of the Valley*, *Narcissus*, *Hyacinths*, and *Tulips* may be included in such a group, it is impossible to determine what view they may take.

GYPHOPHILA FOR VASES: S. G. R. *Gypsophila paniculata* is the species most used in floral decoration and this is abundant at midsummer. The plant is a perennial and requires establishing for two or three years before it will furnish much bloom. The seed should be sown early in the spring and it can also be sown under glass and the seedlings afterwards be planted out when they are well started. *Gypsophila elegans* is an annual species and this comes very quickly from seed. Successive sowings of *G. elegans* may be made from now onwards. The first named species will grow freely in any good garden ground and requires little attention after it is once established. *G. elegans* is often grown under glass for early use, but it can be sown in the open ground in early spring.

IDEAL BOILER: Alpine. We have not had any actual experience of the "Ideal" boiler and therefore are not in a position to say anything as to its heating capabilities. There are several good boilers of the Saddle type that would answer your purpose, such as the "Plain Saddle," with 2-inch waterway, the "Chatsworth," with waterway terminal end and return flue over fire-box, and the "Gold Medal" boiler, having waterway front and back ends, with three return flues over the fire-box, one in the centre and one at either side. A No. 24 Plain Saddle would cost from £11 7s. 6d. to £18 10s., No. 7 Chatsworth from £16 10s. to £19 10s., and a No. 3 Gold Medal would cost from £18 to £21, the difference in prices of the respective boilers is determined by the thickness of plate, one being made of 3/4-inch plate and the other of 3/8-inch, and the approximate heating power of each boiler is 1,000 feet of 4-inch pipe. The above prices are exclusive of furnace fittings, which would amount to £4 10s., £3 10s. and £4 respectively. A No. 1, 6 feet 6 inch horizontal tubular boiler (complete) would only cost £16 10s., and it is capable of heating 1,250 feet of 4-inch pipe. It would practically last a lifetime. Second-hand boilers are more often than not dear at an apparently low price.

There are several first-rate types of tubular and other heating apparatuses referred to in our advertising columns.

KEW HAND-LISTS: *Duramen*. Apply to the Curator, Royal Gardens, Kew.

LOBELIA: W. B. The young plants of bedding *Lobelia* are attacked by a fungus, *Phoma devastatrix*. Spray with a solution of potassium sulphide, at the strength of one ounce in three gallons of water, and afford the plants plenty of light and ventilation.

MUSHROOM-BED: R. J. The Mushroom spawn is overrun with a parasitic fungus. Your best course will be to remove the bed, and thoroughly disinfect the interior of the house before making a fresh bed with materials obtained from a different source. It is, however, possible, that the parasite was introduced with the spawn.

NAMES OF FLOWERS, FRUITS AND PLANTS.—We are anxious to oblige correspondents as far as we consistently can, but they must bear in mind that it is no part of our duty to our subscribers to name either flowers or fruits. Such work entails considerable outlay, both of time and money, and cannot be allowed to disorganise the preparations for the weekly issue, or to encroach upon time required for the conduct of the paper. Correspondents should never send more than six plants or fruits at one time: they should be very careful to pack and label them properly, to give every information as to the county the fruits are grown in, and to send ripe, or nearly ripe, specimens which show the character of the variety. By neglecting these precautions correspondents add greatly to our labour, and run the risk of delay and incorrect determinations. Correspondents not answered in one issue are requested to be so good as to consult the following numbers. **FRUITS:** T. A. Flanders Pippin.—R. A. C. B. Fillbasket.—Subscriber. The fruit is very much bruised and past its season. Send specimens earlier another season.

PLANTS: J. R. & T. 1, *Cupressus Lawsoniana* var. *aurea*; 2, *Juniperus drupacea*; 3, *Retinospora pisifera aurea*; 4, *Abies Nordmanniana*; 5, *Pinus* probably *monticola*; 6, *Juniperus sinensis*; 7, *Cupressus Lawsoniana*.—P. C. 1, *Fabiana imbricata*; 2, *Grevillea rosmarinifolia*; 3, *Daphne Mezereum*; 4, *Streptosolen Jamesoni*.—Fellham. 1, *Oncidium prætextum*; 2, *Odontoglossum gloriosum*; 3, *Brassia caudata*; 4, *Cypripedium venustum*; 5, *Cœlogyne speciosa*; 6, *Aerides vandarum*.—A. S. Portions of barren fronds of Ferns are not suitable specimens to send for naming, especially without a description of the habit of the plant. 1, *Blechnum occidentale*; 2, probably *Callipteris esculenta*; 3, *Cibotium Schiedeii*; 4, *Lastrea trichodes*; 5, *Aspidium coriaceum*.—W. C. S. *Odontoglossum mirandum* Rchb. f., a very close ally of *O. Lindleyanum*.—A. L., *Tunbridge*. *Dendrobium speciosum* Bancroftianum Rchb. f. —J. W. *Iris japonica*.

NOTICE TO TERMINATE ENGAGEMENT: IV. B. You do not state whether your position is that of head gardener or assistant. Assuming you were engaged in the capacity of journeyman, a week's notice on either side would be sufficient, notwithstanding that the wages are paid fortnightly.

PRIMULAS: H. T. We have seen many better.

VIOLETS: *Violetii*. The leaves are attacked by *Cercospora violæ*, one of the three fungi so destructive to violets. Dilute Bordeaux mixture is the only spray that really arrests the disease, and this should be applied when the leaves are young. The soil should also be covered with the solution.

WINTER HELIOTROPE: J. C. & Sons. This popular plant is named *Tussilago* (*Petasites*) *fragrans*.

WOODLICE IN PLANT HOUSES: S. Obtain a tin of Steiner's Vermin Paste and mix some of the poison with barley meal or middlings, and then spread it on pieces of glass, wood, or tin, and place near the haunts of the woodlice. In a week or ten days most of the pests will be exterminated. The poison can be obtained from chemists.

WINTER WORK IN FRUIT PLANTATIONS.

III.

DISTRIBUTING farmyard manure in a fruit plantation devoid of any other roadways than the headlands is slow and laborious work, whether done by means of barrows or willow baskets, known locally as "trugs." Of course, the manure is carted and laid in large heaps on the headlands; but to convey it all over the field is a work of time. Partly for this reason, and partly for the like inconvenience in setting out tubs of spraying wash and in the work of spraying, roadways, as stated in my first article, have been left in plantations recently laid out.

Digging, or, rather, forking with hop spuds, is done only in the older plantations in which horse-cultivation is no longer practicable. Where that can be carried on by means of a Planet Junior cultivator, by working late in the autumn and as soon as the soil is dry enough in the spring, weeds can be kept down fairly, hand-hoeing being done around the trees and bushes during the spring, summer, and autumn. This season, fortunately, horse cultivation was possible as early as the last few days

of February, whereas last year, in consequence of wet weather having driven the work into the Potato-planting season, it could not be started until two months later. But digging must be done where horse cultivation is not possible, expensive though it is. In Kent it is done for 18s. to 24s. per acre, but it costs me 25s. to 30s.

This extra price is caused, at least partly, by the extraordinary tendency of my land to lay itself down to grass. The texture of the soil is very fine in a mechanical sense, and grass and weed seeds, possibly hay seeds from the manure, germinate quickly and freely, so that a month after hoeing in the growing season it becomes almost a pasture. In digging, therefore, the land has to be turned over carefully to bury the grass thoroughly, and not thrown over (thrown forward) after the fashion of digging with hop spuds in Kent. This increases the expense of the work, and, besides, the soil is possibly less easy to dig than most of the Kent land.

PRUNING.

The pruning of Apples in the older plantations, largely done by myself, is now finished, but that of young trees planted in December or early in January is being left until the buds begin to start, in order to make sure of cutting the young branches back just above a vigorous bud pointing in the right direction. I am not a believer in the plan of leaving newly-planted trees until the year after planting before cutting them back. The theory of its advocates is that root-growth is stimulated by leaving the branches on the trees for the first season, but this seems to me fallacious reasoning. The roots, reduced by breaking and the necessary trimming when the trees are transplanted, do not want the extra demand upon their resources involved by having to nourish long branches. Moreover, as is always the case when the balance between branches and roots is in favour of the former, much of the energy of the latter is directed to the development of fruit buds. We see this in root-pruning, done for the very purpose of developing fruit buds, and newly-planted trees are root-pruned trees. Subject as my district is to summer drought, I know from experience with trees not cut back enough in the spring after planting what would happen if they were not cut back at all in the first season. They would form fruit buds right up the young branches from the trunk to the tips. It is all very well to say, "Cut below the fruit buds in the second season," but I have had trees in which no wood bud could be found below the fruit buds on some branches. Besides, why promote this waste of energy in the development of fruit buds that are to be cut away?

My Plum trees are not now pruned until March, because when they were pruned in the autumn, or at any later time before the end of the winter, there was much trouble in ends of shoots dying off down to the second, or, in some cases, the third bud left, and the snags had to be cut off afterwards, a very undesirable addition to the work. Nor was this all the disadvantage, for the new growth, instead of coming from the end bud left in pruning, which pointed in the right direction, came from a bud which, as likely as not, pointed the reverse way. Presumably, the dying-off was caused by frost acting on wood not fully ripened. At any rate, the fault is avoidable by doing the pruning in March.

To revert to the older Apple plantations, formed six years back from last autumn, in pruning the trees recently I have been freshly impressed with the futility of stereotyped rules as to pruning. Not only do different varieties require different treatment, but individual trees of the same variety also need modifications in pruning. Here is a well-furnished tree, with

strong young shoots that require a little thinning, perhaps, but no pruning of the shoots left at all. There we have a weak tree, with long and very thin shoots, that need to be cut back severely, or stunted shoots covered with fruit spurs, so that cutting back to the old wood is necessary if the tree is not to be a permanent dwarf. Often this excessive formation of fruit spurs is on only one side of the tree, and then that side requires treatment different from the pruning advisable for the rest of the tree.

TO KEEP THE BRANCHES OFF THE GROUND.

Again, "cut to a bud pointing outwards" is a common direction, but some varieties of Apples try all they can to lie on the ground, so that cutting just above a bud pointing upwards is desirable for them. Notably, I have found this to be the case with some Lane's Prince Albert, planted later than the other trees, to replace some unsatisfactory ones removed. They were feathered half standards when they were received, and they were topped in order to train them as bushes, like the rest of the trees. It is a pity that they were topped at all, as nearly all the growths have been directed downwards, and it is only by cutting the buds pointing upwards that they have been brought into decent shape in three or four years. On the other hand, there is the converse difficulty with King of the Pippins and Duchess of Oldenberg, which try to grow like Lombardy Poplars. For them the policy is that of cutting to buds pointing outwards, and keeping them from getting too dense inside.

There is a third class of trees which, although they do not form pendent branches, send their growths out almost horizontally, so that many shoots need to be cut to buds pointing inwards.

BRAMLEY'S SEEDLING, WARNER'S KING, AND WORCESTER PEARMAN.

Another illustration may be given to show the difference in pruning needed to get trees of certain varieties well furnished with branches during the training period. Bramley's Seedling and Warner's King, if not cut back somewhat severely for the first two or three years after the planting, form long and sturdy branches far too thinly disposed, whereas, on the other hand, Worcester Pearmain forks out in several directions above a cut, and gets much too dense with branches if cut back at all severely. This, at least, is my experience with these varieties.

VARIETIES WITH GOOD HABITS.

Lastly may be noticed those blessed varieties which form model bushes if left almost entirely alone after the first two years from planting. Cox's Orange comes just into this class, where it grows sturdily enough, and Allington Pippin, Beauty of Bath, Lady Sudeley, Blenheim Orange, and Lord Grosvenor are better still in this respect. For models of nicely-rounded and well-furnished bushes, however, Royal Jubilee, Domino, and Golden Spire "take the cake," while, so far as can be judged at present, Charles Ross seems likely to deserve to be classed with them. Golden Spire must be cut back severely to outside buds at starting, as it has a little too much of an upright habit of growth, and is none too sturdy on any but a rich soil; but, so treated, it makes a bush of beautiful shape.

PLUMS

also require very different treatment for the different varieties. While Victoria makes long and pendent shoots, too thinly disposed, and requires to be cut hard to buds pointing upwards, Monarch is of too upright a habit, needing quite different treatment, while Czar and Pond's Seedling with me tend to grow too compactly. Early Rivers is not suited to the bush form at all,

and it has been more trouble to get into any approach to a fair shape than all other varieties together. If cut back much it makes a mass of short and spiky growths, pointing in every direction. But perhaps my stock of this variety is particularly obdurate against proper shaping. They were wild-looking things when I received them; and if Plums ever are budded on the Blackthorn, I should imagine that mine were

FROGMORE GARDENS.

It would be difficult to conceive any private horticultural establishment including glass houses, offices, and kitchen garden that is carried out on a larger scale and on a more utilitarian system than that at Frogmore.

The details in connection with the new buildings are complete, although the latter are on a colossal scale. The heating arrangements for the

fires. The houses themselves are arranged on the corridor principle, and are light and convenient, with ample provision for water in each. In the corridors, sliding doors are employed. These open easily and obviate the danger of slamming, and thus of breaking glass during windy weather. The floors are especially well made, being either iron gratings, mosaic, or a composition, and all have a neat appearance.

FIG. 73.—PALAZZO ORENCO, THE ITALIAN RESIDENCE OF THE LATE SIR THOMAS HANBURY.

(For text see page 172.)

so raised. Perhaps, however, they were budded on the Myrobalan, and this variety, in my opinion, should be budded on the Mussel. Gisborne is the best model of the bush shape among my varieties of Plums.

The winter is ending as I finish my record of its work and the rigmarole of reflections arising therefrom, and it is a comfort to see all kinds of fruit exceptionally backward in development. *A Working Grower.*

many glass houses require 12 miles of 4-inch piping. The mains are laid in a tunnel, and are thus available for inspection from the two stoke-holes to the point where they enter the separate houses. This is a commendable method, and one most useful in the case of leakage. The boilers are each 22 feet in length. The stoke-holes are built in a huge iron tank on account of the lowness of the situation, and to prevent the water percolating and rising higher than the

An interesting feature at the southern end of the range of plant houses, where the ground is lower, necessitating a step up into each house, is a rockery, furnished with low-growing Alpines, bulbs, &c., which must have a pleasing appearance in springtime.

Plants are cultivated on an extremely large scale. At the time of my visit, one span-roofed structure contained 200 large plants of *Eucharis grandiflora* that were most profusely flowered;

indeed, I have not seen so beautiful a display before in the case of this plant. *Eucharis* mite is disregarded at Frogmore, and certainly with a good reason. *Begonia Gloire de Lorraine* was represented by 700 plants. Many were large specimens, and it would be difficult to find a bet-

In the fruit department the same good condition was everywhere apparent. A batch of 9,000 Strawberry plants in pots were giving the best of promise for a goodly supply of fruits. The recently-planted vines are grown on the single rod system: such varieties as Muscat of

order for a period of at least 30 years. Fine Grapes will no doubt be obtained from these vines in the near future. The Peach trees promised equally well, handsome fruit being borne by those so recently planted, and the appearance of the wood was all that could be desired.

FIG. 74.—SHOWING THE SITUATION OF THE LA MORTOLA GARDEN OF THE LATE SIR THOMAS HANBURY.

(For text see page 172.)

ter batch in foliage and in flower, especially when the smallness of the pots is taken into consideration. Winter-flowering *Pelargoniums* are great favourites, judging by the large stock of plants seen. *Gardenias*, too, were in luxuriant health and in large numbers.

Alexandria and Lady Downes were being treated on common-sense lines in pruning, in not being allowed to fill their allotted spaces too quickly, an all too common cause of failure among vines.

Vines grown on the single rod system should be planted with the view of their lasting in good

A very fine Grape room has lately been built, capable of holding 1,300 bunches, arranged on stands, with abundant space around them for inspection. The bunches are contained in bottles specially designed by Mr. McKellar, in which when the bunch is placed the bottle does

not tip and allow the water to escape as in the ordinary bottle. This appears to be a capital invention.

Much attention has been paid to the hardy fruit department. Peaches on walls furnished with a coping promise exceedingly well. They were planted last year in the best of loam, which evidently suits their requirements, judging by the growths they have made. Apricots on south and west walls are receiving much attention, and their appearance give promise.

Apples, too, are largely planted as wall trees, Cox's Orange Pippin in particular. An extremely fine row of bush trees of this variety had recently been planted, this Apple being in much request at the Castle. The trees were large ones when planted, some would say too large for successful removal, but now they are established the wisdom of planting such trees is apparent.

What will be an exceedingly fine grass orchard has been planted with the best varieties of standard trees. This is several acres in extent, but a thorough system of trenching was given the land, and it has since been planted with bulbs for a spring display, 100,000 being put in last autumn.

Roses are receiving a large share of attention, no fewer than 300,000 plants having been added during the last three years: the bulk of these are Tea and Hybrid Tea varieties. *E. Molyneux.*

FOREIGN CORRESPONDENCE.

THE TULIP DISEASE: ITS PREVENTION OR CURE.

THE many complaints that have been received during the last few years through the seedsmen and the trade generally, both in this country (Holland) and in Germany, as to Tulips in parks and private gardens failing to bloom; and in many places failing to come up altogether, justify us in giving the results of our trials and investigations in this direction for the benefit of all those interested. We have for the last three years been making extensive trials, based upon the discoveries of Professor Dr. H. Klebahn at Hamburg, who not only succeeded in finding the cause of the Tulip disease, but also the fact that it makes its appearance in two distinct states as if caused by two fungi, viz., *Botrytis parasitica* and *Sclerotium tuliparum*.

We will refrain from going too much into details. Generally the disease caused by *Botrytis* shows itself in the early spring by the very backward and sickly appearance above ground of the first Tulip sprouts, or by their failing to appear at all. Upon lifting such diseased bulbs, the cause of it, in the shape of numerous small black fungi, about the size of a pinhead, or in the case of *Sclerotium tuliparum*, by larger dark brown fungi, can easily be detected adhering to the old bulb or what is left of it. These fungi are usually there by many hundreds at a time together, and under favourable circumstances, viz., in a damp atmosphere, they seed very freely in the spring, and thus cause a very rapid infection of the soil or of the surrounding plants of Tulips. As these fungi will keep alive and retain their vitality for at least two years in the ground, it is not surprising that some grounds are so badly infected that no Tulip bulb will grow in it any more. It would be an easy matter to kill these fungi by application of such disinfectants as "Carbolineum," but experience has proved that the cure is as bad, or worse, than the disease, because it will make ground so treated unfit for any vegetation whatever for several years to come.

The only practical plan, therefore, we find is to lift out any of the bulbs that show signs of the disease, together with the surrounding soil, and at the earliest moment in the spring, taking great care that nothing of it is spilled, and that

all is completely destroyed by burning. If this process is, however, not done with very great care, it had better not be done at all, as the slightest spilling of the infected ground will only cause more spreading of the infection.

The foregoing suggestions are based upon the results of our own trials so far, but may be improved upon in the future as experience may teach us.

As a practical demonstration of the results obtained by the careful weeding out during several years of any suspected subjects, our own Tulips are sufficient evidence. *Polman-Mooy, Bulb Growers and Nurserymen, Haarlem, Holland.*

TREES AND SHRUBS IN SCOTTISH GARDENS.*

(Continued from page 153.)

ABERCAIRNEY.

This place is about four miles out of Crieff and is situated in an undulating well-wooded park. The planting of the coniferous trees was done mainly about 40 years ago, and the growth being particularly good some fine specimens are now to be seen. Taking first the Silver Firs: *Abies Nordmanniana* is 63 feet high; *A. concolor*, 65 feet high and 5 feet in girth (a big specimen); *A. cephalonica*, 75 feet high; *A. grandis*, 90 feet high and 10 feet in girth; these splendid trees were all in perfect health and shape. A good specimen of *A. pectinata* girthed 15 feet 9 inches. The most interesting Spruce was *Picea orientalis*, 63 feet high. The Tsugas, too, were admirable: *Tsuga Mertensiana*, 84 feet high; *T. Pattoniana*, 40 feet, and its glaucous variety (*T. Hookeriana*) 30 feet high. Of the Pines I was most struck by *Pinus Cembra*, 63 feet high and 5 feet 7 inches in girth. A tree of *Larix leptolepis* was interesting as showing the rate of growth of this tree in Scotland; it was planted 23 years ago and is now 42 feet high. The Irish Juniper (*J. communis* var. *fastigiata*) makes here a rigid column 20 feet high and 3 feet through. These figures show that, although the dimensions of some of these trees are exceeded elsewhere, the general level of excellence is exceptionally high.

OGHTERTYRE.

Oghtertyre is situated about 2½ miles out of Crieff in a large, picturesquely hilly park, from which fine views of the surrounding country can be obtained. The garden has long been famous for its Conifers, and probably no locality, even in Scotland, is better adapted to the cultivation of a large number of evergreen trees and shrubs. Much of the present attraction that Oghtertyre has for tree-lovers is due to the late Mr. Geo. Croucher, who was gardener there for 45 years under Sir Patrick Keith Murray and his father. He planted most or all of the rarer trees.

A feature of special interest is the number of garden varieties of Conifers. Of the Douglas Fir, for instance, there is the finest specimen in the country of the variety *Stairii*; it is 39 feet high, well furnished, and of a pale greenish-yellow which is not only distinct, but ornamental. Of the Golden Douglas Fir, a rare variety, there is an admirable tree 40 feet high, and the very glaucous variety is represented by a specimen of the same size in perfect health and colour. The Golden Scots Pine, *Pinus sylvestris* var. *aurea*, is here a big bush 16 feet high and as much in diameter; this variety has the curious habit of assuming its highest colour in winter, turning greener as summer approaches. The glaucous variety of *Picea Engelmanni* [pungens?] is 25 feet high, and the golden variety of *Cupressus pisifera* (commonly known as *Retinispora plumosa aurea*) is 18 feet high, 15 feet in diameter, and in excellent colour.

Turning to the species themselves, *Picea ajanensis* impressed one by its magnificent health and the vivid blue-white colouring of the lower surface of its leaves, which is not surpassed, I think, by that of any other plant in cultivation; one specimen was, approximately, 45 feet high. *Saxegothea conspicua*, a curious Conifer with some affinity to the Yew, introduced from Chili in 1847, is now very rarely

met with; it is, however, in fine condition at Oghtertyre, a plant being 12 feet high and 8 feet through. The Silver Firs have the usual rude vigour of these trees in Perthshire, a specimen of *Abies cephalonica* being unusually fine. I was unable to take its height, but its trunk was 8 feet in girth. Then *A. magnifica* I saw 79 feet high and finer than elsewhere. This species is much less common than its ally, *A. nobilis*, one of the most frequent of purely ornamental Conifers in Scotland. At one time these two species were confused, but seen in the adult stage they are very distinct, *A. magnifica* being denser in habit and much more slender and tapering in form. *Picea Morinda* had a trunk 8 feet 8 inches in girth and was 66 feet high, and of the common Spruce I saw a tree 120 feet high.

It is not only the Conifers that thrive so well at Oghtertyre, some of the ordinary evergreens are very good also. A specimen of Portugal Laurel, for instance, was 30 feet high and 30 feet through; *Ilex crenata*, 7 feet high; *Rhododendron dauricum*, 8 feet high; *Pieris floribunda*, splendid bushes, 10 feet through.

MONZIE CASTLE.

This place, which is about three miles out of Crieff, I visited in a persistent downpour of rain. Although it has not much of unusual interest to arboriculturists, it is worth visiting for the sake of its three enormous Larches. These are planted together in a row, and are said to be of the same age as the more famous trees at Dunkeld, and to have been planted a few days earlier. The largest of them I made to be 108 feet high and 17 feet 6 inches in girth; it is, therefore, about equal to the larger of the Dunkeld Larches. Of other trees I noted *Populus deltoides*, 120 feet high, and the common Birch, 84 feet high. New to me as a hedge plant was the Douglas Fir; it answered the purpose, however, very well, being dense and well furnished.

DALKEITH PALACE.

The gardens of Dalkeith have long been known as among the leading ones of the United Kingdom. Managed by a succession of famous gardeners, they have constituted a school of horticulture from which many noted men have been sent out. One reason of this is that the place is what may be termed an "all-round" one, where neither the kitchen garden, the flower garden, nor the hothouses absorb more than their due share of the attention of the staff, but all are good. For this reason the trees and shrubs, though they constitute a very interesting collection, do not predominate as they do in other famous places I visited. The climate is considerably drier than that of Perthshire, consequently the growth of many Conifers, more especially Firs and Spruces, is not so luxuriant as it is there. Still, I found the Himalayan Juniper *Juniperus recurva*, a fine bush 14 feet high and through, and there are three fine old Cedars, one of which girths 13 feet 9 inches. Ginkgo biloba is represented by one of the fine specimens of this country, 50 feet high and very healthy, as are *Abies Veitchii*, 20 feet high, and *Picea pungens*, 18 feet high.

Many years ago the varieties of the Scotch Rose (*R. spinosissima*) were very popular in gardens. Most of them are now almost lost to cultivation, and it was, therefore, a pleasant surprise to find a collection here of about ninety varieties got together by a former Duke of Buccleuch in the early part of the nineteenth century and still carefully guarded.

Among the trees, mention should be made of a very fine weeping Ash, 50 feet high; *Ilex dipyrrena*, 20 feet high; and a remarkable old specimen of *Laburnum*, low, and spreading in habit, and covering a piece of ground 60 feet across. To one whose lot is cast in the south one of the notable differences in the ordinary vegetation of Scotland from that of the south of England is the predominance of the Scotch or Wych Elm over the common *Ulmus campestris*. In the south the Wych Elm is comparatively rare. Here at Dalkeith is the noblest specimen I have ever seen; it is 125 feet high, with a clean trunk girthing 13 feet 9 inches at 4 feet from the ground.

SMEATON-HEPBURN.

The garden of Sir Archibald Buchan-Hepburn at Smeaton in Haddingtonshire is more to the

* Contributed to the *Kew Bulletin of Miscellaneous Information* by Mr. W. J. Bean.

eastern side of Scotland than any other I visited. The growth of the trees and shrubs, however, appeared to me to be quite as luxuriant as in Perthshire, the proximity of the North Sea and the Firth of Forth, I suppose, accounting for this. The Conifers were especially good, some of

species was introduced, is now 90 feet high and girths 13 feet 6 inches. Its ally, *S. sempervirens* (Red wood), was 66 feet high and 9 feet 3 inches in girth, and therefore about the same size as our biggest Kew specimen. *Tsuga canadensis* has the big bushy head characteristic of

and 10 feet 4 inches in girth; as an ornamental tree, however, it has one frequent defect, the centre of the tree being filled with dead branches and twigs, which the outer fringe of living growth is not dense enough to hide. Other trees finely represented were *Pinus excelsa*, *P.*

FIG. 75.—VIEW IN THE LATE SIR THOMAS HANBURY'S GARDEN AT LA MORTOLA.
(For text see page 172.)

them better than I saw elsewhere. *Cupressus macrocarpa*, 72 feet high and 7 feet 6 inches in girth, was finer on the whole than any other I met with, though one on Sir Herbert Maxwell's estate almost rivals it. *Sequoia gigantea* (Wellingtonia), said to have been received from Kew as a small plant soon after the

the tree in Scotland, 40 feet through. *Abies nobilis* is represented by a noble specimen approximately 100 feet high, with a trunk 8 feet 10 inches in girth. *Picea Morinda* was 72 feet high and 7 feet 9 inches in girth. *P. sitchensis*, of which I saw elsewhere such large trees, is here almost as fine as anywhere—90 feet high

insignis, Douglas Fir, *Abies Pinsapo*, and *A. grandis*, all girthing about 8 feet. A good specimen of the cut-leaved Oak, *Quercus pedunculata* var. *heterophylla*, was 54 feet high. Of big shrubs, I noted *Neillia opulifolia*, 30 feet through, and *Spiraea discolor*, 20 feet high.

(To be concluded.)

CLEANSING OF WATER-COURSES.

THE attention of the Board of Agriculture and Fisheries has been drawn to the damage stated to be caused by the neglect of certain occupiers of land to keep clean the channels of water-courses and streams running through their land. It has been suggested that the law which deals with this subject is very little known, and the Board considers that it will be useful to publish, in the form of a leaflet, a short summary of the legal position.

For mere omission a man is not, generally speaking, answerable by law; and, accordingly, at common law, the occupier of land through which a water-course runs is not, as a rule, under any obligation to neighbours whose lands drain into that water-course to prevent or remove any obstruction of the outfall due to merely natural causes (such as silting up of the channel or growth of weeds), and not caused by any action on his part, though, in exceptional cases, *e.g.*, under an enclosure award, such an obligation may sometimes exist.

A statutory remedy is, however, provided by the Land Drainage Act, 1847 (10 & 11 Vict. c. 38), and it appears to be applicable irrespective of any existing legal obligation on the part of the occupier of the land; but the statutory duty imposed by this Act arises only on notice given by the person injured, and the Act does not create any statutory liability in damages for the injury caused by the occupier's neglect.

Section 14 of the Act enacts that where, by the neglect of any occupier to maintain or join in maintaining the banks, or to cleanse and scour or join in cleansing and scouring the channels of existing drains, streams, or water-courses lying in or bounding the lands of such occupier, injury is caused to any other land, the proprietor or occupier of any land so injured may serve a notice on the neglecting occupier requiring him to maintain the banks or cleanse or scour the channels in question. If he neglects so to do, the occupier of the land injured may, after one calendar month from the service of the notice, carry out the necessary work. The cost of the same or a just proportion thereof is to be paid by the neglecting occupier, and payment may be enforced by an order of justices.

Section 15 provides that, unless the drain, stream, or water-course to be cleansed bounds or immediately adjoins the land of the occupier injured by the neglect, a justices' warrant to enter on the defaulter's land in order to carry out the necessary works must be obtained. This warrant is to be granted if the justices are satisfied that the injury has been caused by the neglect of the occupier whose land is to be entered.

December 1906.

The Week's Work.

THE FLOWER GARDEN.

By A. C. BARTLETT, Gardener to Mrs. Ford, Pencarrow, Cornwall.

Hardy Ferns.—Last year's fronds may now be removed from the deciduous Ferns, and any unsightly fronds from the evergreen kinds. Frequently other plants, such as spring-flowering bulbs, are grown amongst the Ferns, which will preclude any digging, so that the cultivator must be content with applying a top-dressing, composed chiefly of leaf-mould, or spent hot-bed manure and old potting-shed soil, mixed together in equal proportions, which will suit most species. The Limestone Polypody will thrive the better if some lime-rubble is mixed with the soil. The Spleenworts, which naturally grow out of crevices, do not seem to require any soil assistance, but when endeavouring to establish these Ferns a handful of leaf-mould pushed into the crevices will assist root formation. The present is a good time for moving hardy Ferns and for making new Ferneries. Speaking generally, a low, rugged rockery is a suitable formation. Conditions may there be found to suit the varying requirements of the different species. Shade is essential for Ferns, but it must not be too dense. Although Ferns like moisture, they will sicken in a stagnant soil.

Lawn-mowing.—Search the lawns for stones and see that the lawn mower is thoroughly oiled before the first mowing takes place. Choose a

dull day in preference to a sunny one, as there is then not so much danger of a frost, which, following immediately after the first cutting, would blacken the grass.

Hedges.—Any growth that was made in the Holly hedges after the last autumn clipping may now be pruned. Care must be taken, or the hedge will become too wide at the top, and, in consequence, thin below. Clear out any weeds, or Ivy that may have become established, and after lightly forking the surface soil apply a top dressing. As April is the best time to plant the Holly, preparations for this work must now be made, deeply digging the soil, and working into it a good dressing of farmyard manure. As a hedge to border the Rose garden, the Penzance Briars are very appropriate; the common Sweet Briar makes a very good hedge, and will stand a deal of pruning. The various forms of *Pyrus japonica* are also adapted for forming hedges, and if, after they have grown to the desired height, due attention be paid to summer-pruning, they soon form flowering spurs. Lavender and Rosemary hedges have much to recommend them where the style of gardening requires divisions of medium height.

Cordylina australis.—Seeds sown now in pans of light soil and placed in heat will quickly germinate, and if kept growing in light, rich soil will, by June, have formed plants which, when duly hardened off, will be useful as small "dot" plants for carpet bedding, or to plant near the outsides of "foliage" beds, &c.

PUBLIC PARKS AND GARDENS.

By W. W. PETTIGREW, Superintendent of the Parks and Open Spaces in the City of Cardiff.

Hatching of fish (continued from p. 154).—The necessary apparatus used in the incubation of trout ova may either be placed under cover or out in the open, just as circumstances demand. If under cover, the structure used may be of stone, brick, or wood, and for the purpose of keeping a steady atmospheric temperature within, should always be roofed with heather, straw, or some other good non-conducting material, and, provided utility is secured, the whole structure may be of the cheapest possible character.

The building.—When it was decided to erect a hatchery in one of the parks here, it was naturally arranged to put up a building in keeping with its surroundings, hence it was built of brick and covered with a thatch roof. In view of its being of educational value to school children, &c., it was made larger, and more roomy than there was otherwise any necessity for, and to add a further interest a part of the building was converted into an aquarium, where various kinds of coarse fish—with occasionally a few of the trout bred in the hatchery—are exhibited in glass tanks. The whole of the building is 37 feet long by 16 feet wide, and the portion devoted to fish-hatching is in all 12 feet by 16 feet—ample space in which to hatch far more trout than we require for our own use.

Open-air hatchery.—Since this building has been put up we have formed an open-air hatchery, where it is possible to incubate 100,000 trout ova at one time.

Necessary apparatus.—The most important apparatus required in a hatchery is a number of shallow boxes in which the trout eggs lie during incubation. Where wooden boxes are used the ova should rest on glass grilles or on zinc trays, rather than on the wood. With slate boxes this precaution is not needed, as the ova do not suffer harm from resting on the slate. A constant supply of pure water has to flow over the eggs at all times, for if the water be allowed to stand in the boxes for any appreciable length of time it soon becomes charged with the carbonic acid gas given off by the eggs, and the eggs are killed. If the water supply is derived from a stream that runs any risk of becoming dirtied during wet weather, it must be passed through a number of filters before it is allowed to come in contact with the eggs, otherwise there would always be the chance of a deposit of dirt taking place on the eggs, when the results would be disastrous. On the contrary, while water which is obtained from a good spring need never be filtered, it ought to be broken up and aerated as much as possible before it reaches the hatching boxes, to get rid of some of the carbonic acid gas with which spring water

is often charged. In our main hatchery we are fortunate enough to have the town water supply laid on, while the one in the open air is fed by a beautifully clear spring. In the former we have 12 slate trays, capable of holding between 25,000 and 30,000 ova. If it were not for the fact of our arranging the hatching boxes in such a way as to admit the public to view the process, there would be ample room for ten times as many ova as is laid down each season.

A "decoy" pond.—As the stream which supplies our lake is mainly the property of the city, we deal a little more freely with it in making provision for capturing and breeding fish than might be possible if it belonged to a number of different landowners. For instance, with a set purpose in view, we have constructed a decoy pond leading off from the stream at a point where a dam crosses it. By having this decoy pond it is not necessary for us to keep a stock of breeding fish, as we are always able to secure as many as we require. During the summer and autumn this pond is used as a rearing pond for the young trout, but about the end of September they are taken from it and placed elsewhere. In November the screens which divide it from the brooks are removed, and as soon as the winter floods commence the trout, failing to get over the dam, enter the pond, where they are easily captured. This contrivance would hardly be allowed on every stream where trout fishing is carried on!

(To be continued.)

FRUITS UNDER GLASS.

By ALEXANDER KIRK, Gardener to J. THOMPSON PATON, Esq., Norwood, Allos, Clackmannanshire.

Muscat vines are now showing the inflorescence which will develop generally at the third or fourth leaf of the lateral shoots. At this stage the atmospheric temperature at night should be 60° to 65°, allowing a rise to 70° by day, and 85° with sun heat. Damp the paths and borders once or twice daily. Admit a "chink" of air through the top ventilator when the weather is favourable, and shut up with sun heat early in the afternoon. Prevent currents of cold air from reaching the foliage. Shut down the hot-water valves in the morning if there is the promise of a bright day. Keep the atmosphere of the house close and warm, but an excess of moisture at this stage would have a tendency to cause the bunches to become long and loose. This will often happen in the case of old vines if they are syringed once or twice daily. I neither practise nor recommend the syringing of vines, except when they are attacked by red spider. As soon as the lateral shoots have made five or six leaves, pinch the points out of them; this will be one or two leaves beyond the bunch. Pinch all sub-laterals at the first leaf. Do not hasten to have the laterals tied in to their permanent positions, but let this be done by degrees and with great care. As soon as all the bunches have run out to sufficient length, select the best on each lateral, and cut off the others.

Earliest vines in pots.—These will require to be very carefully watered with warm manure water twice weekly, reducing the supply of water at the roots as soon as the berries commence to develop colour. Employ rather more ventilation as the days lengthen, and keep the atmosphere much drier. Red spider will soon make its appearance if the house or plants are too dry and hot. Employ the syringe if red spider actually attacks the pot vines.

Strawberries.—When several batches of these are coming forward, care must be taken that all the batches are not in the same degree of heat. Those that have been removed to a shelf in the Pine stove, Melon or Cucumber house, and are now swelling their fruits, will require an atmospheric temperature of 60° to 65° at night, with 10° to 15° higher by day. Place stakes or twigs to each truss of fruits. Thin the berries, leaving eight or ten of the largest and best-formed to each pot. Afford the plants tepid liquid manure twice a week, and maintain a moist atmosphere. When the berries commence to develop colour, reduce the amount of moisture, and admit air more freely. Plants coming into flower will require heat equal to 55° to 60° at night, and 10° higher with sun heat by day. Pollinate the flowers at mid-day by means of a camel's-hair brush or rabbit's tail. Remove succession batches from the frames into late Peach houses.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir Trevor Lawrence, Bart., Burford, Surrey.

Thunias.—The following species of *Thunia* as *T. Marshallii*, *T. Bensoniæ*, *T. alba*, *T. candidissima*, *T. pulchra*, and the hybrids *T. Veitchiana*, *T. Brymeriana*, &c., are invaluable for exhibition purposes during the early summer months. All of them are of easy culture, but they succeed best in a comparatively hot atmosphere, such as is generally maintained in the East Indian house or plant stove. These deciduous plants will need immediate attention as to potting; the young growths at the base of the old stems have already commenced to develop, and it is important to do the work before these shoots begin to produce new roots. The plants should be turned out of their pots, and the whole of the soil shaken from them, all dead roots cut, and the stems thoroughly cleaned of scale insects or red spider, by washing them in strong soft-soapy water or the XL-All insecticide wash. The usual method of growing *Thunias*, six or eight stems in a clump, is a very convenient one, as when the plants are in bloom the drooping spikes have a better effect than when they are cultivated singly in small pots. Select clean, good-sized pots, according to the strength of the plants, and half-fill them with crocks for drainage, placing a thin turf of fibrous loam over them. I have tried these *Thunias* in various kinds of compost, and find the stems keep more dwarf and sturdy and bloom more freely in the following mixture than any other:—Good fibrous turfy-loam, three parts; leaf-soil, broken crocks, and coarse silver sand mixed together, one part. Pot the plants in the usual manner, but not too firmly, or most of the roots would remain close to the surface instead of penetrating to the whole depth of the soil. Tie each stem firmly in its place by means of strong neat sticks. For a few weeks after re-potting, keep the plants in the house where some of the *Dendrobiums* are at rest and where the atmospheric temperature at night at this season is kept at between 55° and 60°. Afford them little or no water until the shoots have grown to several inches in length, when the plants should be removed to the lightest position in the warmest house, elevating them well up to the roof glass. Increase the supply of water as the growths lengthen, and when thoroughly established and the roots are numerous, afford them an occasional watering with weak liquid manure.

Materials for potting.—During the next few weeks many plants will need attention as to re-potting, &c., therefore it is advisable to obtain a good store of Orchid peat, and living sphagnum-moss, also plenty of small crocks; place a sufficient quantity of fibrous loam on the potting bench, which will be required for species of *Habenaria*, *Thunia*, *Calanthe*, &c.

Anguloas, &c.—*Anguloa Clowesii*, *A. uniflora*, *A. Ruckerii*, *A. eburnea*, *Chysis bracteata*, *C. aurea*, *C. Limminghii*, *C. lævis*, *C. Sedenii*, *C. Chelsonii*, and others of this type are commencing to grow, but, as the flowers develop in conjunction with the young growths, the plants should not be disturbed by re-potting, which is best done when the flowers have faded. Keep the *Anguloas* in the intermediate house, but the *Chysis* should be suspended close to the glass in a shady corner of the *Cattleya* house. Plants of both genera should be given sufficient water to keep their roots moist until the time arrives for re-potting. The young growths and flower buds of *Chysis* are frequently disfigured by a small yellow species of thrip; therefore, whether these insects be present or not, see that these plants obtain a goodly share of the fumes of the vaporising compound when fumigating the structure.

PLANTS UNDER GLASS.

By J. G. WESTON, Gardener to H. J. KING, Esq., Eastwell Park, Kent.

Ivy-leaved Pelargoniums.—Young plants rooted last season should be re-potted, giving constant attention to the stopping and tying of the shoots. Old plants that have been wintered in a cool, dry house, now commencing to grow, and are intended for forming specimen plants, should be re-potted and placed in an atmospheric temperature of 55° to 60°, affording

ventilation whenever the outside conditions are favourable. Train the plants carefully to stakes, and arrange the growths with the idea of completely covering the stakes. Large plants are useful either for conservatory decoration or for use in the pleasure-grounds, flower-garden, or terrace.

Zonal Pelargoniums.—To provide plants for flowering in autumn and winter, cuttings may now be inserted in boxes or pots. If space is limited, insert a number together in boxes, and place the boxes on the hot-water pipes, where there is a very moderate heat. As soon as roots have been made, put up the cuttings singly, and place them in a position exposed to the light, either on a shelf or in a frame well up to the glass. Re-pot them when necessary, and later in the season, when they are established in their flowering pots, they should be stood on a bed of ashes in a sunny position out of doors. Keep all blooms pinched off until the end of August. Remove the plants indoors at the end of September, or earlier, if heavy autumnal rains are more than usually prevalent.

Primula × Kewensis.—This beautiful hybrid flowered very freely all through the winter, and its clear yellow flowers were a great contrast to the different forms of *P. obconica*, with which it has been associated, the cultural treatment necessary for the one being suitable for the other. Seeds of *P. × Kewensis*, *P. sinensis* var. *stellata*, and *P. obconica* may be sown during the present month, if early-blooming plants of *P. stellata* are required in autumn. Sow the seeds in pans filled with very light, sandy soil, made moderately firm, and cover the seeds very lightly. Place a piece of glass over the pan, and stand it in a frame for preference, where there is an atmospheric temperature of 60°. Keep the pan shaded from the direct rays of the sun, taking great care that the soil never becomes quite dry, this being a frequent cause of failure with small seeds.

Hydrangeas.—The early batches of these in full growth will now require liberal stimulants, also copious supplies of water. The latest plants are starting into growth naturally. Both *H. Hortensia* and *H. paniculata grandiflora* are very useful for growing in pots.

Flowering shrubs will now require very little forcing to get them into bloom. Do not subject them to much heat after the blooms show colour.

Tulips, Narcissus, and Hyacinths now require no forcing, the different varieties coming into bloom very quickly at this season. Remove to a cool house or frame any required to be kept back.

THE KITCHEN GARDEN.

By WILLIAM H. HONESS, Gardener to C. COMBE, Esq., Cobham Park, Surrey.

Early Potatoes.—Tubers should now be planted in a position where they will receive the protection of a wall or hedge, but if this is not possible, a few should be planted on the warmest border available, and later on, when they appear through the ground, afford them protection each night. Select those varieties known to have good cropping qualities, and with a dwarf haulm such as *Sharpe's Victor*, *May Queen*, &c.

Maincrop Potatoes.—Where large quantities of these are grown for the winter's supply, the seed-tubers, if not already prepared, should be at once thoroughly and carefully examined, particularly if the presence of any bad ones is suspected, previous to being put in bags for their conveyance to the fields or elsewhere. Planting should be commenced at the end of the present month, or early in April. The variety *Up to Date* still appears most popular, and several of the newer introductions are very similar to this variety. *Dalmeny Beauty*, in spite of the large tubers it produces, finds favour here, for its cooking qualities at this time of the year are unexcelled.

French Beans will now be giving good results in pots, but as the weather becomes warmer, they will require even closer attention, and more frequent syringings, or they will quickly fall a prey to red spider and thrips. Sowings may now be made for raising plants for planting out in a cold house or in frames to yield a supply

after the last batch of those forced, and before Beans will be procurable out of doors.

Celery.—Plants raised from earlier sowings are liable to bolt, unless lifted early for consumption. The main sowing should now be made in a light, rich soil. Any of the following varieties may be selected:—*Standard Beiser*, *Aldenhams Park*, *Sandringham White* and *Solid White*. The receptacles in which the seeds are sown should be placed in a moist atmosphere that is kept at a temperature of 55° or not higher than 60°. As soon as germination has taken place, let the seedlings be placed near to the glass, and prick off the most forward plants as soon as any are large enough to be handled, leaving the smaller ones a week or more longer; this will help to prevent the plants becoming weakly and drawn. Afford more fresh air gradually as growth advances and the atmosphere out of doors becomes warmer. The most backward plants from the sowing will be considerably behind those that are first pricked out, and will form a late batch, which may be useful for flavouring soups, if not required for planting out in trenches. If the trenches for Celery can be made at an early date, the ridges might be utilised for crops of French Beans, Lettuce, early Turnips, &c., which would all be ready for clearing off before the Celery will need earthing-up.

THE HARDY FRUIT GARDEN.

By J. MAYNE, Gardener to the Hon. MARK ROLLE, Bickton, East Devon.

The Grape Vine.—With a succession of summers like that of last year one could recommend an extended culture of out-door Grapes, but in the average season many of the bunches of fruit fall a prey to mildew, or fail to ripen in a proper manner. A vine or two are to be found in many an old garden, planted more for the purpose of their foliage than for their fruit, the former being largely used for dishing up ripe fruits, being more durable than leaves gathered under glass protection. Intending planters should choose a southern aspect, and for preference a brick wall, as such walls retain the sun's heat much longer than stone. A well-drained soil is essential, and good, friable loam to the depth of 18 or 24 inches is ample. It is better to allow a little extra width than let the roots get down into the cold subsoil. Keep the border rather above the ordinary ground level in low situations and where a heavy rainfall is registered. Commence planting at once; shake away all the old soil, then uncoil and spread out the roots evenly, covering them with about 3 inches deep of soil, which should be well worked down among them as covering proceeds. Fasten the cane to the wall, and as the season advances, see that the roots do not suffer from the want of water. All necessary pruning of the vine ought to be done as soon as the foliage falls in the autumn. The old Dutch Sweetwater, Royal Muscadine and Reine Olga are suitable varieties, the first-named being, perhaps, the most reliable.

General work.—Examine autumn and more recently planted trees, treading well around any that may have got loosened by the wind, and see that no stake or support is injuring the bark of the tree. Any badly-rooted trees that have been transplanted and show signs of still remaining dormant should be syringed overhead two or three times daily when the weather is bright, and all blossom buds removed as soon as they become visible. The weather during the past fortnight has been favourable to the destruction of weeds on fruit quarters. Further sprayings of fruit trees and bushes must now be put off until another winter. Although the winter has been more severe than for some years past, there is but a few days difference in the first open flowers of the Apricot, for coping and netting had to be put up here on the 7th inst. It is a pleasure to record a plentiful show of blossom buds on nearly every variety of fruit tree and bush. Keep a sharp look-out on Black Currant bushes for "big-buds," removing any to the fire than can be found. Some cultivators syringe their bushes with a mixture of equal parts lime and sulphur, after being boiled down; 6lb. of each in 12 gallons of water, putting about a quarter-pint of this into a 4-gallon can of water. It may be preventive, but is not a cure. In the case of badly affected bushes, the wisest plan is to grub them all up and burn them, choosing a new station for replanting next autumn with clean stock.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY, MARCH 16—German Gard. Soc. meet.

TUESDAY, MARCH 19—
Roy. Hort. Soc. Coms. meet.
British Gard. Assoc. Ex. Council meet.

THURSDAY, MARCH 21—
Linnean Soc. meet.
Torquay Spring Fl. Show.
Manchester & North of England Orchid Soc. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—41.5°.

ACTUAL TEMPERATURES:—
LONDON.—Wednesday, March 13 (6 P.M.): Max. 52°; Min. 41°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, March 14 (10 A.M.): Bar., 29.9; Temp., 45°; Weather—Bright sunshine.

PROVINCES.—Wednesday, March 13 (6 P.M.): Max. 48°; Lancaster; Min. 37°, Scotland S.E.

SALES FOR THE ENSUING WEEK.

MONDAY—
Liliums, Perennials, Roses, Azaleas, &c., at 67 & 69, Cheapside, E.C., by Protheroe & Morris, at 11.

WEDNESDAY—
Azaleas, Hardy Plants and Bulbs, Liliums, Palms and Plants, at 11; 4,000 Roses and Fruit Trees at 1.30 and 4; by Protheroe & Morris, at 67 & 68, Cheapside, E.C.
Plants, Roses, Lilies, &c., at Steven's Rooms, King Street, Covent Garden, W.C.

FRIDAY—
Hardy Bulbs and Plants, Roses, Azaleas, &c., Choice Orchids from various sources, all at 67 & 68, Cheapside, E.C., by Protheroe & Morris; the compact Freehold Nursery, Mimbridge Nursery, Woking, Surrey, with Greenhouses, Piping, &c., at the Mart, Tokenhouse Yard, E.C., by Protheroe & Morris, at 2.

The announcement of the death of Sir Thomas Hanbury on the 9th inst., at La Mortola; near Ventimiglia, will be read with regret as deep as it is widespread. He was born in 1832 at Clapham, a member of a family well known for a succession of representatives distinguished in many departments of industry, science, and philanthropy. To horticulturists Sir Thomas is best known by his munificent gift of the late Mr. George Wilson's garden at Wisley to the Royal Horticultural Society in 1903. Chiswick, with all its glorious associations, was no longer suitable for the proper carrying out of its appropriate functions. Each year the local conditions became worse. At the same time, the necessity of a home for the Society was equally or even more pressing. Every Fellow of the Society, and many besides, will remember how, by the most happy conjunction of favourable circumstances, the hall was built mainly in consequence of the devotion of Baron Schröder, and the garden at Wisley secured for the use of the Society entirely by the liberality of Sir Thomas Hanbury. Thus was the centenary of the R.H.S. a matter which had elicited prolonged discussion and much difference of opinion most appropriately celebrated. Although this timely and most serviceable donation is the circumstance which will elicit the grateful remembrance of the larger number of horticulturists in this country, it is by no means the only

claim that Sir Thomas had on the gratitude and esteem of his associates. After some years of successful enterprise as a merchant at Shanghai, Sir Thomas purchased the Palazzo Oregno at La Mortola, a little Italian village just beyond the French frontier at Mentone, and near the old Italian town of Ventimiglia, about midway between the towns of Nice and Genoa. Here, with the assistance of his brother, the late Mr. Daniel Hanbury, a botanist and pharmacologist of eminence, he set to work to establish an experimental botanic garden, in which were cultivated as many of the noteworthy plants of various countries as would thrive in the generally favourable though sometimes trying climate of the Genoese Riviera. Working in association with the late M. Thuret and M. Naudin, of Antibes, the authorities at Kew and many other distinguished botanists and horticulturists, Sir Thomas amassed a particularly interesting collection of plants. How rich it was may be judged from the lists that he was wont to send us yearly of the plants in flower about Christmas or New Year's Day

THE LATE SIR THOMAS HANBURY, K.C.V.O.

as well as from the exchange lists that he issued periodically, and the many illustrations of remarkable plants that have been published in these columns. A long chapter is devoted to this garden and its contents in Strasburger's "Rambles on the Riviera," an English version of which was published in 1906 by T. Fisher Unwin, of Adelphi Terrace, and noticed in our columns at the time of publication.

"No visitor to Bordighera or Mentone should omit to make an excursion to La Mortola, the garden of Sir Thomas Hanbury. The public are admitted on Mondays and Fridays on payment of one franc. This money helps to support the Hospital of Ventimiglia. Those wishing to study in the garden will receive permission from the owner to visit it at any time. The beautiful Palazzo still standing in the grounds takes its name from the former owners, the Oregno family of Ventimiglia. When Sir Thomas Hanbury acquired this estate in 1866 there was a scanty Olive grove on it. With the aid of experienced and skilful gardeners he has converted it into the fairy-like spot which now charms the visitor. The late Mr. Daniel Hanbury, F.R.S., F.L.S., &c., brother of the owner,

assisted with his scientific knowledge in laying the foundation of this vast collection of plants. The garden covers an area of about 40 hectares. It slopes up steeply from the sea to a height of 300 feet, where the road passes through the village of La Mortola. The deep hollow in the nummulitic limestone in which part of the garden is situated affords protection against winds, and permits of the development of such luxuriant vegetation as can scarcely be equalled on the Riviera. It is, indeed, only by irrigating the whole estate that the summer drought is prevented from being fatal to the plants. For at La Mortola they reckon on over 200 cloudless days in the year; and even during the six winter months there are only about 40 rainy days.

"It would be a rash endeavour to attempt to describe the innumerable plants which have been brought together in the gardens of La Mortola. I can do no more than mention its rich profusion and splendour, and draw attention to the valuable information which every visitor can there glean for himself. For each plant bears a label, on which is inscribed its name, native country, and natural order. A catalogue of the garden, published in 1899, included about 3,600 different plants. Since then their number has been much augmented by the addition of new species of scientific interest or technical importance. All botanical institutions duly receive the catalogue, with permission to draw upon the treasures of the garden for scientific purposes. Sir Thomas Hanbury is careful to entrust the management of his garden to competent hands. Hitherto this duty has fallen to the lot of industrious and scientifically-trained gardeners. Mortola is almost unique among private gardens, and should arouse the emulation of other wealthy landowners."

The Botanical Institute of Genoa, under the direction of Professor Penzig, was also founded by the Cavaliere Hanbury, as he was styled in Italy, and numerous works of beneficence and charity were unostentatiously performed by him. The writer of these notes was privileged on one occasion to visit one of the village schools supported by Mr. Hanbury, as he then was. Observing the intimate terms in which he seemed to be with the clergy of the neighbourhood, some dignitaries of the church being present on the occasion, it was interesting to observe how a foreigner and a member of the Society of Friends had succeeded in gaining the esteem of the Roman Catholic clergy. Where beneficence and the welfare of his neighbours had to be considered, differences of creed and nationality were not suffered to intervene; for instance, it is reported that only a few days before his decease Sir Thomas gave £2,000 for a public garden at Ventimiglia. We are glad to hear that Mr. Arthur W. Sutton, a member of the Scientific Committee of the R.H.S., attended the memorial service which was held at Mentone on the 13th inst.

OUR SUPPLEMENTARY ILLUSTRATION to the present issue affords a glimpse of a portion of the great Temperate House in the Royal Gardens, Kew, as it appears in spring-time. The Acacias, Camellias, Rhododendron (Azalea) mollis, Prunus, Pyrus, Cerasus, and species of the warmer temperate zone are in bloom, and at such a season this house may be seen at its best. At all seasons of the year the extreme variation in the foliage of the different species is interesting, and this feature is shown in the present illustration, where the striking appearance of the Cordylines and Phormium is impressive, but when the spring flowers arrive they add an appreciative gaiety to the scene. Reference is made in another column to the remarkable garden that belonged to

VIEW IN A PORTION OF THE TEMPERATE HOUSE, KEW, IN SPRING-TIME.

Temple Press Ltd., Printers, 7-15, Rosebery Avenue, London, E.C.

the late Sir THOMAS HANBURY in the Italian Riviera, where it is possible to grow out of doors under Italy's sunnier skies most of the plants that in this country thrive the better for having such protection as the Kew Temperate House affords them. A descriptive account of the principal species in this house was printed in our issue for July 23, 1904.

LINNEAN SOCIETY.—At the evening meeting to be held on Thursday, March 21, 1907, at 8 p.m., the following paper will be read: Messrs. E. A. JEWELL ARBER, M.A., F.L.S., and JOHN PARKIN, M.A., F.L.S., On the Origin of Angiosperms. Exhibitions: 1, Miss HELEN WARD, Water-colour sketches of Alpine Flowers; 2, Mr. J. BURTT-DAVY, F.L.S., Photographs of Transvaal trees and tree-cenery.

BRITISH GARDENERS' ASSOCIATION'S CERTIFICATE RECOGNISED BY THE CARDIFF CITY COUNCIL.—The Cardiff City Council on Monday last passed a resolution to the effect that trained gardeners (as defined by the British Gardeners' Association) employed in the Parks Department shall be paid 27/- per week, and upon their passing the Royal Horticultural Society's Parks Employees' Examination they shall receive an increase of one billing per week per annum until a maximum of 50/- be reached.

THE ROYAL SOCIETY.—Among the 15 selected candidates (out of over 90 representatives of all ranks of science) for admission to the Royal Academy this year we notice the name of Mr. H. N. RIDLEY, formerly of the Natural History Museum, and for several years director of the Botanic Gardens, Singapore. The selection will have to be confirmed by the Fellows. Mr. RIDLEY is an occasional contributor to these pages.

PREVENTION OF CORRUPTION ACT, 1906.—The following extract is taken from the Board of Trade journal lately issued. "Cases of commissions being offered by certain foreign firms on orders secured in this country having been brought to the notice of the Board of Trade, the Board desire to draw attention to the 'Prevention of Corruption Act, 1906,' by the provisions of which the acceptance, or agreement to accept, by an agent, or the offer, or agreement to offer, to an agent, of anything in the nature of a secret commission is punishable on conviction by imprisonment, with or without hard labour, for a term not exceeding two years, or to both imprisonment and fine, or, on summary conviction, to imprisonment, with or without hard labour, for a term not exceeding four months, or to a fine not exceeding fifty pounds, or to both such imprisonment and fine. The Act came into force on the 1st January, 1907."

THE BARONESS BURDETT-COUTTS.—We extract from *Nature* the following interesting note:—If a scholarship was to be established at Oxford, in classics, or history, or even theology, butience claimed her aid. Such things were not done at haphazard. She would spare herself no trouble both to search out both the need and the means. With a touch of characteristic humour she enquired of Sir WILLIAM HOOKER whether Kew Gardens, so far up the Thames, was not poor sea-weeds. She had already found out the fact that had secured the GRIFFITHS collection so rare and extensive that without impairing the central completeness it provided duplicates for six other botanical establishments. She probably had not read SCHIMPER's monograph on the genus *Sphagnum* and did not know the details of the muscological collection of BRUCH, but she found out that he also wanted mosses and that SCHIMPER's great herbarium could be acquired; thus, not so much by wealth as by thoughtful insight, special departments of British science were enriched at her hand."

THE "CHILLINGHAM" ORCHID SALE.—The sale of duplicates from the collection of the Right Hon. the Earl of TANKERVILLE, which took place at Messrs. PROTHEROE & MORRIS' Central Auction Rooms, on March 12, proved very successful, the 251 lots realising in the aggregate £3,283. *Odontoglossums* were the favourite plants as usual, and the highest price attained was for lot 152, *O. crispum* Leonard Perfect, 700 guineas. It is a part of the remarkable plant shown by Messrs. SANDER & SONS, at the Temple Show, 1906, and illustrated in the *Gardeners' Chronicle*, June 2, 1906, pp. 248-9. Lots 64 and 140, being two plants of *O. crispum* Mabel Whateley, brought 180 and 200 guineas respectively; 168, *O. crispum* Brilliantissimum, 180 guineas; 208, a similar plant, 140 guineas; 52, *O. crispum* Tankerville, 100 guineas; 116, *O. ardentissimum*, Chillingham variety, 100 guineas; and other *Odontoglossums* fetched good prices. Of the *Cypripediums* a small plant of one of the most beautiful, lot 172, *C. Thalia giganteum*, brought 50 guineas; 105, *C. Victory*, 40 guineas; 100, *C. x Earl of Tankerville*, 50 guineas; 60, *C. Lord Ossulston*, 17 guineas; and the prices realised for good forms of *C. euryades*, *C. aureum*, and other of the older favourites in some cases were higher. The best price for a *Cattleya* was for lot 155, *C. Warneri alba*, 220 guineas, and in this class the white varieties well maintained their value. Lot 84, *C. Dowiana Rosita*, realised 42 guineas, and throughout the sale appeared to be very satisfactory.

POTATO VIOLET COMMERMSONI AND BLUE GIANT.—The controversy still rages over these varieties. The *Revue Horticole*, in its issue for March 1, calls attention to a lecture by M. VINCEY. With regard to the three varieties of Potato Violet Commersoni, Blue Giant and Richter Imperator, one and, better still, two dressings of copper sulphate certainly caused an increase in the yield; but it is remarkable that, even without any dressings and with the largest amount of irrigation, Violet Commersoni yielded a much larger crop than did Blue Giant and Richter Imperator after two applications. All the conditions of the irrigation being otherwise equal, with two copper dressings in each case, the yield of Violet S. Commersoni was more than twice as large as that of the two other potatoes. From this experiment, M. VINCEY draws the following conclusions:—(a)—For cultivation on a large scale, more especially in a very permeable soil, alternately moist and dry owing to irrigation with sewage matters and with a food supply far exceeding the requirements of the crop, Violet S. Commersoni is a valuable acquisition owing to its exceptional quality for supporting, satisfactorily, intensive applications of sewage. (b)—As regards general cultivation also, this variety is of much interest owing to its resistance to mildew and its total yield and proportion of starch. (c)—In its characteristics, under cultivation at any rate, Violet Commersoni is an entirely different plant to Blue Giant.

ATTEMPTED SUICIDE.—At Richmond police court, on Friday, February 22, a clerk of West Kensington, was charged with threatening to commit suicide by taking poison, on the previous day, in Kew Gardens. Mr. JOHN MASTERS HILLIER, keeper of the museum at Kew Gardens, saw the man leaning against a bay for about half an hour, and when accused left he found that a fracture in a big glass door of a case containing atropin had been made much worse, the glass having been smashed. He gave the attendant strict injunctions to watch in case the man returned again, as he did the next day. The attendant then told witness that accused had been tampering with the case again. Witness asked him what he was after, and prisoner replied, "Atropin; I want to take a dose." He added, "I have nothing to live for." After other evidence had been given, the Bench discharged accused after he had expressed regret for his proposed action.

GUERNSEY, with an area of about 40 square miles, has, it is estimated, 8,000 growers for market. *American Florist*.

COMMERCIAL MOTOR EXHIBITION.—At this exhibition at Olympia, London, which will close on the 18th inst., Messrs. BOULTON & PAUL, Ltd., Norwich, are exhibiting in the motor boat section, and Messrs. RANSOMES, SIMS & JEFFERIES, Ltd., Ipswich, are showing motor lawn mowers.

LEGISLATION FOR FRUIT-GROWERS.—Mr. J. A. PEASE, on behalf of Sir E. STRACHEY, stated, in the House of Commons on March 8, that the President of the Board of Agriculture hopes shortly to introduce legislation by which local authorities would be given power to deal with insects and other destructive pests in their districts in order that fruit-growers might be protected.

DRESDEN HORTICULTURAL EXHIBITION.—The International Horticultural Exhibition to be held at Dresden from May 4 to May 12 is attracting much interest. The usual German fashion of exhibiting plants as in cultivation or growing naturally is always very costly. The German public is not much interested in gardening for the simple love of plants; they require some special attractions. The Rhododendrons and Alpine plants must be shown in the frame of a landscape of the Caucasian mountains, for instance, or the water and bog plants as we find them in the woods, the Orchids and Bromeliads must be arranged on the trees of a Brazilian jungle; a background so built up is very popular, and so are dioramas. This kind of exhibits may seem to a scientific or specialist grower rather superfluous, but it is in conformity with the taste of the German public. Indeed, the horticultural exhibitions of Dresden are really picturesque arrangements, celebrated over all Germany, and amply worth a visit. The same plan was carried out in 1904 at Dusseldorf, where the Rhododendrons were shown in that manner by a Dresden gardener and won many admirers, who until then had not known that Rhododendrons are hardy in the German climate. The aim of these decennial international exhibitions is to show the development and progress of the various horticultural productions; of winter-flowering plants, as Azaleas, Camellias, Rhododendrons, and Irises. In addition to these, that are grown for the markets of the eastern half of the Continent, for the last 10 years Lily of the Valley, the Lilac, forced Roses, and foliage plants (Palms, &c.), for the decorations of rooms and winter gardens, have been largely cultivated. All these plants will be shown in enormous quantities in an exhibition-palace, very well adapted to display them in the style above mentioned. It is a pity indeed that the plants and flowers must be brought together for the short period of one week, but the labour will not be thrown away, as the German, Austrian, Prussian, and other foreign gardeners and plant-lovers are expected to be present in large numbers. The King of Saxony, the traditional patron of these exhibitions, will open it, and it is expected that the Kaiser may come, as he did in 1896, and so secured a very large attendance of the public. A special show of Orchids will be arranged (certainly not on the jungle scheme), including fine varieties and hybrids, and only for a duration of three days (May 4-7). Some of the first Orchid-cultivators of England, Germany, and Belgium will take part in the exhibition. *F. Leden, Dresden*.

—We note the appearance of the schedules for the various sections of the Dresden Horticultural Exhibition. These classes are as follows:—A, 1, Palms and stove plants; 2, spring flowers and cool greenhouse plants; B, Orchids; C, principles of horticulture; D, floral decorations; E, landscape gardening and buildings; F, water plants; G, fruit trees; H, vegetables; I, forestry, Rose and tree culture; K, bulbs, horticultural products and implements; L, Cacti and other succulents.

THE EFFECTS OF FROST AT ABBOTSBURY.

THE recent severe weather has killed such a number of plants in the sub-tropical gardens here (coast of Dorset) that I am induced to write a few notes on the genera and species which may be of interest and perhaps some use to those who intend planting Australian, South American, and other plants of a tropical and semi-tropical nature in similar localities.

The gardens here are frequently likened to the Garden of Eden by visitors in the summer-time, but had they visited them on Saturday, January 26, when there were 4 inches of snow nearly all over the gardens, and 3 feet in depth in places where it had drifted, the thermometer registering 16° Fahr. of frost all the time, I think their idea of a similitude to the Garden of Eden would have been shattered.

In the spring of 1905 I planted out between 400 and 500 young *Acacias* and *Eucalyptus*, and nearly all of them are killed. The species of *Acacia* killed are as follows:—

<i>A. floribunda.</i>	<i>A. armata.</i>
<i>A. cuneata.</i>	<i>A. falcata.</i>
<i>A. Dietrichiana.</i>	<i>A. myrtifolia.</i>
<i>A. longifolia.</i>	<i>A. rostellifera.</i>
<i>A. microbotrys.</i>	<i>A. saligna.</i>
<i>A. harpophylla.</i>	<i>A. trinervis.</i>
<i>A. ricinifolia.</i>	<i>A. verticillata.</i>
<i>A. eburnea.</i>	

The smaller plants of *Acacia dealbata* are nearly all killed, but, fortunately, the large plants, which were sown in 1896 and are now about 40 to 50 feet in height, are perfectly safe. It has always been considered that *Acacia floribunda* was the hardiest species, but I think, without exception, all are killed, even plants up to 20 feet high. *A. melanoxylon* has survived in places; in fact, this has stood much better than *A. floribunda*, although some specimens of *A. melanoxylon* 20 feet high have been quite killed. *A. rostellifera*, *A. verticillata*, *A. Riceana*, *A. extensa*, *A. trinervis*, *A. longifolia* are all killed, and other species have suffered.

The species of *Eucalyptus* which have been killed are as follows:—

<i>E. corynocalyx.</i>	<i>E. maculata.</i>
<i>E. crebra.</i>	<i>E. viminalis.</i>
<i>E. corymbosa.</i>	<i>E. "Fodd Bay."</i>
<i>E. amygdalina.</i>	<i>E. goniocalyx.</i>
<i>E. bicolor.</i>	<i>E. Gunnii.</i>
<i>E. coriacea.</i>	<i>E. leucoxylon.</i>
<i>E. eugenioides.</i>	<i>E. platypus.</i>
<i>E. ficifolia.</i>	<i>E. Risdoni.</i>
<i>E. paniculata.</i>	<i>E. punctata.</i>
<i>E. melliodora</i> (even plants 35 feet high).	<i>E. polyanthemosa.</i>
<i>E. pitularis.</i>	<i>E. rostrata.</i>
<i>E. siderophloia.</i>	<i>E. Stuartiana.</i>

E. Globulus, *E. Gunnii*, *E. urnigera*, *E. coccifera*, and *E. cordata* have survived. The hardiest species, in my opinion, are *E. urnigera*, *E. coccifera*, and *E. cordata*.

The Bamboo family has stood very well. The only species killed outright are *Arundinaria Hookeri* and *A. spathiflora*. The following species suffered severely, but, I think, will survive:—*Dendrocalamus Falconerii*, *Bambusa gracilis*, and *D. Decaisneana*.

We have a collection of 17 *Buddleias*, but they all escaped except *B. madagascariensis*, *B. asiatica*, and *B. Columbica*, which are killed outright, *Buddleia auriculata* being injured badly.

The New Zealand *Laburnum* (*Edwardsia grandiflora* and *E. microphylla*) have suffered much; all the leaves are falling off fast, but the flowers are still safe. The plants have suffered more than they have been known to do previously.

We took great care of all our big plants of *Cordyline australis*, otherwise they would have been killed. Some of the stems are over 20 feet high. We have, however, lost about one dozen plants. *Cordyline atropurpurea*, I think, is quite killed.

There is a good collection of *Senecios* grown here. Species not hardy enough to stand more than an ordinary winter are *Senecio eleagnifolia*, *S. grandiflora*, *S. Forsterii*, and *S. Grayii*.

The following have either suffered severely or have been killed:—*Beschcorneria yuccoides*, *Furcroya longeva*, *Aloe frutescens*, *A. maculata*, *A. ferox*, *Agave ferox*, *A. applanata*, *A. mitriformis*, *A. Mellerii*, and *A. Houlettiana*.

The miscellaneous plants that have been killed include *Callistemon styphelioides*, *Melaleuca tomentosa*, *Ehretia serrata* [acuminata], *Guevina avellana*, *Westringia rosmariniformis*, *Grevillea longifolia*, *Coronilla glauca*, *C. valentina*, and *C. viminalis*, *Olearia argyrophylla*.

Even Bays, Portugal Laurels, Myrtles, *Eugenia*, *Pittosporums*, and *Escallonias* suffered very much, but are not killed outright.

FRUIT REGISTER.

ARD CAIRN RUSSET.

To Mr. Baylor Hartland, of Ard Cairn, Cork, we are indebted for samples of this Apple, received at the end of February. The fruit is about 2½ inches long by 2¼ inches in width, ovoid-conic, truncated and slightly five-angled at the top, with a shallow eye, short funnel-shaped tube, and infolded calyx-segments. Stalk about half-an-inch long, set in a shallow basin. Skin golden-brown, more or less covered with russet. Flesh firm, yellowish-white, with a sweet, rich flavour. In view of St. Patrick's day, our artist has added a few Shamrock leaves.

FIG. 77.—ARD CAIRN RUSSET (IRISH) APPLE, ASSOCIATED WITH SHAMROCK.

Altogether, this has been considered the most severe winter for many years, and it has thrown us back a long way. Still, the *Magnolias*, *Himalayan Rhododendrons*, *Camellias*, and *Azaleas* are so full of bloom that there will be a good show, but I grieve very much over those that are killed, as they would have been such good plants with this season's growth. The chief lessons to be learnt is to plant tender things in as sheltered positions as possible.

I shall be glad to answer any question as to the hardiness of tropical and sub-tropical plants as grown here. *H. Kempshall*, *Abbotsbury Castle Gardens*, *Dorsetshire*.

EARLY FLOWERS OF "MALMAISON" CARNATIONS.

At the meeting of the Royal Horticultural Society, on February 16, much interest was evinced in a group of *Souvenir de la Malmaison* Carnations shown by G. F. RAPHAEL, Esq., Porter's Park, Shenley, Hertfordshire (gr. Mr. Albert Grubb). The date of season was specially early for such an exhibit, the quality of which may be judged by an inspection of the illustration at fig. 78.

Mr. Grubb is very successful in the culture of this type of Carnation, and during the past

month has had a display of flowers which was greatly admired by visitors to the garden. The following remarks by Mr. Grubb on various cultural details will therefore be read with interest:—

"Special attention should now be paid to the plants that are in bud, also to the main batch of plants that are now producing their flower spikes. Manure should be applied freely until the buds show colour, but at that stage it should be discontinued altogether. The manure I use most is Bentley's Carnation Manure, and, for a change, manure-water obtained from the soaking of sheep 'droppings' gathered in the summer time under trees in the park, where the sheep go for shade. The 'Malmaisons' are greatly benefited by this latter, cheap manure. The character of the soil has much to do with success or failure. We use the Northampton loam, which is more easily obtained than the scarce

of Westminster is indispensable, being an early variety, and one that will thrive almost anywhere; the flowers are rather small, but will last in good condition for a longer period than any other. Princess of Wales is the variety most grown here, it having a favourite colour, and one of the largest flowers when well grown. I am under the impression that there is more than one variety or strain under this name. I have a house of plants now in bloom; on some plants the flowers are of a deep colour, while others are quite pale. I need hardly say the pale-coloured varieties will not be used for supplying cuttings for propagation. I have not noticed the pale shade so much until this year. In order to obtain early and strong layers, which are necessary for success, plants should be deprived of some of their side-shoots, leaving only three or four to a plant. Old plants should not be layered unless the cultivator is short of stock."

necessary lime is always present, and warmth, both in spring and summer, helps the bulbs to grow and ripen well. Grown in pans, they need but light and somewhat poor soil, and are better treated if turned out of their receptacles to finish their growth in the open border. Early Irises that can be recommended are *I. Heldreichii*, cobalt-coloured, with violet signal patches; *I. Tauri*, a purplish counterpart with an edging of old gold around the blade; the well-known violet-coloured *I. reticulata* and its forms, *histroides* (Cambridge blue), and *Krelagei* (purple); the hybrids *purpureo-persica* and *Sindpers*, both studies in subtle colouring that well repay inspection; in the former case, rosy-purple is the dominant colour, in the latter one porcelain blue. Other Irises that can be similarly grown are *I. Danfordiae*, a dwarf yellow *reticulata* as regards form; and *I. persica*, whose flowers are palest blue in colour and of exquisite form.

FIG. 78.—EARLY GROUP OF "MALMAISON" CARNATIONS SHOWN AT A MEETING OF THE R.H.S. IN FEBRUARY.

Surrey loam. It is most difficult in some parts to grow 'Malmaisons,' even if loam is purchased. I am glad to say they do fairly well here, and by syringing them occasionally with 'Carvita,' the plants remain free from 'rust' and disease. After this date the grower may venture to keep the plants a little warmer, but it is important at all times of the year to give them plenty of ventilation, and the cooler the plants are kept when resting, the better. I cannot add to or take away anything from the advice given for potting on p. 155 in last week's issue, under the heading of 'Plants under Glass,' which, I think, is very practical—I was glad to see the names mentioned there of some of the best varieties. Maggie Hodgson is one of the finest coloured 'Malmaisons' grown; Duchess

THE EARLIEST SPRING FLOWERS.

QUITE a large number of small-habited, spring-flowering bulbous plants from Asia Minor have become deservedly popular. They help to bridge over an almost flowerless period of the hardy flower garden, linking up the last Christmas Rose with the first Daffodil. Their cultural needs can be pretty fully met in the rock garden, but other ways of using them are suggested by the accompanying figure of a small group grown in pans in a cold frame. Where there is no glass accommodation whatever, these little bulbs may be grown in narrow, warm borders generally to be found close to dwellings. In such borders they may be grown from year to year without preparation; the

Most of these are to be found in the illustration (fig. 79, p. 177). Of Crocuses that can readily be grown in pots or pans, the lavender-coloured *C. Tomassinianus*, the pretty lilac and silvered *C. cyprius*, with deep bronze-purple exterior blotches; *C. thrysanthus*, a small but exquisite yellow; and *C. Sieberi*, a sturdy deep lilac flower that everyone admires, are of the choicest.

There are dozens of others well worth growing in a similar way. Add to these four or five forms of *Cyclamen ibericum* and *C. vernum* in shades of pink and crimson, Snowdrops, Saxifrages of the *Burseriana* group, and the earliest dwarf Fritillaries such as *F. aurea*, *F. armena* and *F. citrina*, and the group becomes representative of the best of the early spring flowers. Readers should appreciate the usefulness and

attractiveness of these little "bulbs" for the jardinière. Grown coolly in pots and pans throughout the winter, they respond to the first day's sunshine, and may be had in flower from the year onwards. Grown in the open, their fragrance is in some measure lost, but in the confined atmosphere of apartments one gets the odour of Violets, Primroses, and other subtle perfumes from practically all the Irises, most of the Crocuses, and from a large percentage of other bulbs that flower with them.

A word of caution. Forcing, as practised with Tulips, Hyacinths, and the rank and file of florists' bulbs, must not be practised with Irises. They grow fast enough without it. Planting should be done not later than October.

LAW NOTES.

RAILWAY RATES.

THOSE who take any active interest in the question of railway rates, and the effect which such rates have upon the trade of the country, are already watching with considerable anxiety the progress through the House of Commons of a small Bill, known as the Railway Contracts Bill, which is likely to come up for second reading at any time on or after the 16th instant. As the Bill is one which affects every reader of the *Gardeners' Chronicle*, it may be useful to explain as shortly as possible the nature of the point involved, especially as there seems to be considerable misconception on the subject at the present time.

The Bill itself merely provides in effect that it shall not be lawful for any railway or canal company to make any condition with respect to receiving, forwarding, or delivering of goods, if the effect of such condition would be to exempt the company from liability for injury to, or loss of, the goods carried where such loss or injury is occasioned by the gross neglect of the company or its servants.

It should be explained that this proposed amendment of the law deals only with conditions customarily inserted by the railway companies in the contracts which they enter into when forwarding goods "at owner's risk." The point does not arise where goods are forwarded at "company's risk," because railway companies in their capacity of common carriers are liable under the Carriers' Act for all risks except those arising from the act of God or the King's enemies, or the inherent vice of the goods (such as a horse which injures itself by vicious kicking), or the inherent tendency of the goods to decay or ignite. But, in the course of time, the companies began to take steps with a view to further limiting their liability as defined above, and the plan hit upon was one whereby the person wishing to forward goods was offered a lower rate for carriage of the goods if sent at "owner's risk" than that which he would have to pay if the goods were forwarded at "company's risk." The trader, being anxious to escape the high rate which the company had legal power to charge when carrying at company's risk, was naturally tempted to accept this offer (though involving signature of a special form of contract necessary to carry this arrangement into effect) an offer on these terms seeming in theory reasonable enough. At the same time, the trader naturally expected that the goods would receive reasonable treatment, even in cases where he signed this special form of contract, but, although the courts have held that these special contracts must be just and reasonable in their conditions, the fact remains that at the present time the rights of the trader have been so whittled down that whatever may be the damage sustained by goods forwarded at his own risk (or in cases where the loss is even a total one) he now finds himself practically unable to recover compensation from the railway except in cases where he is able to perform the almost impossible task of proving wilful misconduct on the part of the company or its servants. In justice to the railway companies, it must be admitted that until recent years ~~were~~ they thought undue hardship had been sustained they paid compensation in many cases where the trader would have been unable to obtain redress by an action at law. Latterly, however, the railway companies have all entered

into an arrangement between themselves in connection with this subject, the practical result of which is that the companies only pay where they can be compelled to do so legally, that is to say, in those cases where the unfortunate trader is actually able to *prove wilful misconduct*. The object of the Bill now before Parliament is to enable the trader to recover compensation in these cases where the company or its servants have been proved guilty of *gross neglect*, although not actually guilty of wilful misconduct. It will surely be generally admitted that the demand is neither unreasonable nor unjust.

The Bill contains a further clause to the effect that the railway companies shall not be justified in raising the "owner's risk" rates merely because of the fact that the law is slightly amended by the Bill as above explained.

It may perhaps be asked why, if the trader chooses to accept the lower rate granted where the carriage is at owner's risk, he should complain if the railway company lose, delay, or damage his goods. The answer is that the power of the railway companies has practically grown into that of a dangerous monopoly, and as usual in the case of monopolies, the trader now finds himself impaled on the horns of a dilemma; either he must pay a very high rate for having his goods conveyed at company's risk, or if he pays the more reasonable rate quoted where his goods are carried at his own risk, he must face the danger of their being totally lost or damaged, even when the railway company has been guilty of gross negligence, without the slightest compensation being vouchsafed to him. What is the trader to do? Take, for instance, the following case which is here quoted for the purpose of illustrating the point involved, while admitting for the sake of fairness that it goes somewhat beyond the average. A trader desired to send Tomatos in open sieves from London to Glasgow, and applied for quotation of rates. The rates quoted by the railway company were 100s. per ton if sent at company's risk, and 42s. 6d. per ton if sent at owner's risk, a difference of over 100 per cent. Could any conceivable state of affairs justify such a distinction? If the trader wished to have the goods safely carried he had to face an expenditure of 100s. per ton for railway charges alone. If this was more than the business would bear his only alternative was to have his goods conveyed, it is true at a much lower rate, but under the unpleasant certainty that if from any cause whatever, except the wilful misconduct of the company's servants, the Tomatos were lost or damaged, the entire loss would fall upon him. Even if the damage arose from the gross neglect of the company or its servants there would still be no redress, and it is this anomalous position which the Railway Contracts Bill seeks to remedy.

During the last generation the volume of railway traffic has of course increased to an enormous extent, and one might reasonably expect to find that in the case of railway companies, as with other commercial concerns, the greater the output the lower would be the figures at which rates could be quoted while still maintaining a reasonable margin of profit. But, unfortunately, notwithstanding the increased volume of traffic, railway charges have not decreased in the proportion which one might feel justified in expecting, even after making allowance for the many excuses put forward, and here again little improvement can be looked for without the pressure of public opinion unmistakably expressed.

It will be seen that the matter is one which, although affecting traders to a vast extent, also affects every member of the public who wishes to consign or receive goods through the agency of a railway company, and it is to be hoped that strong efforts will be made to insist on the Bill becoming law as being at least a step towards reform. It is evident that the railway companies desire to fight the Bill, and, in fact, a deputation of railway managers waited on the President of the Board of Trade only a few days ago in order to protest against it. If growers, and the public generally, desire to obtain the reasonable protection afforded by the Bill they should write immediately to the member of Parliament for their division urging him to give the Bill his support, and assuring him of the urgency of the matter from the trade point of view. The railway companies have thought fit to combine in their own interests, and it now

remains to be seen whether the public will be prepared to combine effectively by due effort on their part before it is too late. Readers are aware that the Joint Railway and Parliamentary Committee, of which Mr. George Monro is chairman, are already hard at work on the subject, but the measure of their success will necessarily depend largely upon the amount of public opinion vigorously expressed in their support. *H. Morgan Veitch, Norfolk House, Norfolk Street, Strand.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

BEGONIA GLOIRE DE LORRAINE.—In respect to this beautiful Begonia it should be mentioned that if plants are cut back moderately after flowering, and they are then placed in a moist, hot atmosphere, they will, in six or eight weeks' time, almost repeat their former beauty. *J. H., Haully Park.*

EARLY PEAS AND SUCCESSION.—The names of these are legion but the varieties are not so distinct, and very often what suits one district or one soil will not do on another. For instance, I sowed last season a very early Pea supposed to be 15 inches high, but which went up 5 feet. I have not found that much advantage is gained by sowing very early. There is always something in the shape of a drawback in the weather, either in the early stages or the latter. The earliest Pea with us last season was Carter's Eight Weeks, but the most profitable one was "Lightning," which was but a few hours in front of Sprigtide, from which we were able to gather abundantly. This Pea matures very quickly, far more so than many others. Early Morn—a first Early Marrow—is a rare good and early Pea, and should be sown in a warm position, when it will prove very remunerative. Daisy still holds good as an excellent second early variety. Commonwealth takes the place of the more known Stratagem, and is the latest relation to that variety, though a good re-selected type of that variety is still in the front. Model Telephone is still a very fine and high-class Pea of delicious flavour. How many different names this class of Pea is sold under! "Quite Content"—which was sent out in small packets last season—proved all that was claimed for it. It is undoubtedly the largest podded Pea ever introduced, and I can fully bear out that statement. It is sure to be extensively sown this season. It requires plenty of room for development and rich cultivation. Exhibition is a famous Pea for all purposes. Dreadnought is a new Pea, and should be sown to succeed Quite Content. Judging by its character last season (a dry one), it is bound to become popular. Michaelmas still retains its position as a good late variety, and one that is very sturdy and of great vigour, and resists mildew to a great extent. I have had that variety really good at Michaelmas, but then, again, soil and situation have much to do with good crops of late Peas. A good selection of that good old Pea, Ne Plus Ultra, is sometimes very difficult to beat as a late variety for flavour and cropping. Sutton's Continuity is an exceptionally good late variety, and the Peas are unique in flavour. I should strongly advise young growers to try several late and early varieties to prove by actual experience which variety does best in their garden, and then hold fast to a good thing. Peas are very often sown too thickly to secure the best results. *W. A. Cook.*

THE JAPANESE LARCH AT GRAVETYE.—Nowhere have I seen the Japanese Larch growing more vigorously than at Gravetye Manor, Mr. Robinson's beautiful estate in Sussex. There, two good breadths of the tree have been planted on different parts of the estate which show well both its ornamental character and rapidity of growth. The warm cinnamon tint of the shoots is quite a remarkable feature of the tree and is only approached by that of a vigorous growing specimen of the deciduous Cypress. The rate of growth is rapid, several of last year's shoots measuring 39 inches in length, and a break planted four years ago is now fully 8 feet high. Should the Japanese Larch thrive in other places as it does at Gravetye its value as a forest tree will be considerable, especially too, as, so far, no disease has appeared. *A. D. Webster.*

A NEW GOOSEBERRY PEST.—As a result of recent work upon the genus of mites known as Eriophyes, of which *E. ribis* (Nalepa), causing "big bud" on Black Currants, is perhaps the most familiar example, I have long held the opinion that many other fruit trees would ultimately be found to possess these mites. Needless to say, wherever they do occur on such plants they are the cause of considerable damage and loss. During the past week I received from an Evesham fruit grower some Gooseberry cuttings on which all the present year's buds appeared dry and shrivelled. The outer leaves were quite dead and the bark in some cases was peeling off in long shreds. I at first suspected a fungus, but no trace of one could be found. I next cut one of the shoots through longitudinally, thinking that possibly some boring larva might be the cause of this shrunken appearance, but nothing was found. As a final resort I next teased a bud, just as one would do to find the Black Currant gall-mite, and I was very much surprised to find a mite of the genus Eriophyes.

bud" in Black Currants. *Walter E. Collinge, The University Department of Economic Zoology, 55, Newhall Street, Birmingham.*

FORCING BY MEANS OF WATER.—Two years ago I noticed in a continental journal the details of forcing by means of hot water, a practice (if I remember correctly) that was initiated in Norway. Last year I gave it a trial, with the result that Lily of the Valley planted afterwards in sand in a forcing pit did remarkably well. The spikes were rather straggly as to time, some being ready to cut much sooner than others. Lilacs were a failure, no doubt because the buds were not so forward as those cut from bushes in warmer summer climates. First and last I have experimented with a great variety of plants, and I would not like to say that immersion in hot water is as valuable an aid to forcing here as it seems to be on the Continent. For some time back we have been furnishing Roses, shoots of flowering Currants, early *Spiræa*, *Nuttallia cerasiformis*, and now Almonds.

WISLEY — HANBURY — WILSON.—The announcement of the death of the generous donor of Wisley Gardens to the Royal Horticultural Society—Sir Thomas Hanbury—serves to draw attention to the fact that, so far as I know, there is in the gardens no object which publicly serves to acknowledge the deceased gentleman's splendid gift. Is it too much to ask that now he has gone the Council should erect some fitting memorial, even were it in the form of a pretty drinking fountain, on which might be fixed an inscription detailing the nature of the gift and the goodness of the donor? In some similar way should also be provided some memorial of the originator of the gardens, Mr. G. F. Wilson. Whilst the present generation may know much of these eminent horticulturists their successors may otherwise know little or nothing. Every year the Wisley Garden is showing improvement. No longer is it dreaded as a white elephant, and, if the situation is remote, for a century at least it will be in pure air and in delightful surroundings. *A. D.*

FIG. 79.—SPRING FLOWERS SHOWN BY MESSRS. WALLACE AT THE LAST R.H.S. MEETING
(For text see page 175.)

An examination of other buds showed that practically all were infected. The species, which I think is undoubtedly a new one, is rather longer than *E. ribis*, and so far as I have been able to make out rather stouter in the cephalothoracic region from above below. A full description with figures will later be published of this species, which I propose to name *Eriophyes grossulariæ*. The purpose of the present communication is to draw the attention of all Gooseberry growers to the new wood of their trees, upon which the buds appear to be dead or drying up. Such should be cut off and immediately destroyed by burning. Any such twigs forwarded to my address I shall be pleased to report upon. Whether this species migrates from affected buds to others yet remains to be seen, but I would point out that unlike affected Black Currant buds they are not globular, or distorted at all on the Gooseberry, and that the mite is already in this year's buds, although they have scarcely commenced to unfold. It is sincerely to be hoped that growers will keep a look-out for this pest and check it in the bud, or they may be confronted before many seasons are past with a disease as bad or perhaps worse than "big

Prunus pissardii, *P. triloba*, *Mespilus canadensis*, &c., are available. The treatment of these is very simple. After cutting, merely place the shoots in water in a hot stove, and in a few days the buds begin to show colour, and in about ten are available for vase furnishing. This kind of forcing treatment does not shorten the life of the flowers, which last a really long time in the house. The beauty of some is enhanced, *Prunus pissardii*, for instance, being very lovely, and the white-flowering Currant is peculiarly sweet. *Deutzias* force exceedingly well, but hardy Azaleas and *Rhododendrons* do not submit to be forced in this way. *Choisyas*, though well forward, fail to respond, and unless it be *Syringa rothomagensis*, none of the Lilacs is satisfactory. The value of cutting the buds of bulbous plants and forcing them into flower is known to market growers, but I am not sure that gardeners as a rule use this means to any great extent. The custom of cutting branches and shoots of trees and shrubs and forcing them rapidly into flower ought to appeal in a special manner to gardeners, because it places at their disposal a vast amount of first-rate material which otherwise is practically worthless. *R. P. B.*

SOCIETIES.

ROYAL HORTICULTURAL Scientific Committee.

MARCH 5.—*Present:* Dr. M. T. Masters, F.R.S. (in the chair); Prof. G. Henslow, Messrs. G. Massee, E. M. Holmes, J. W. Odell, J. Douglas, E. A. Bowles, A. Worsley, R. H. Curtis, F. J. Baker, J. T. Bennett-Poë, C. T. Drury, W. C. Worsdell, A. W. Sutton, G. S. Saunders, H. T. Güssow, and F. J. Chittenden (hon. sec.).

Potato: species and varieties.—Mr. A. W. SUTTON showed an interesting series of Potato plants and tubers as follows:—

1. Plant of *Solanum Commersoni* ("the Potato of Uruguay") belonging to the same stock as seen by the Committee at Reading last July. The flowers of this species are white and sweet-scented, while the fruit is cordiform.

2. Three plants grown from tubers received this winter direct from Uruguay, the tubers being collected from plants growing in a per-

fectly wild state. The collector states that there are two wild types in Uruguay, one bearing white flowers, the other violet flowers.

3. Tubers just received, supposed to be of the same species as the last, bearing violet flowers, but found in another district at a great distance from the last. The tubers were of a considerable size, some measuring over 2 in. in length by 1½ in. across. It will be interesting to notice later on (a) whether the last two are one and the same species, and (b) what relation, if any, there may be between these last two and the type *Solanum Commersoni*, now so well known and recognised. Possibly this violet-flowered Uruguay Potato may prove to be an unknown species.

4. Two plants of *Solanum Maglia* grown from single eyes.

5. One plant of *Solanum Commersoni* Violet (Labergerie), and one of the Blue Giant Potato (Paulsen).

Numbers 4 and 5 were grown from single eyes (along with a large number of others) under the same treatment under glass, in order to test the assertion of Labergerie that a greater tendency to "mutation" is seen when single eyes are removed from a Potato tuber and submitted to a system of intense culture. None of the plants under this treatment at present show any tendency to mutate.

Mr. SUTTON kindly promised to bring these again before the committee when growth had proceeded further.

Intumescence in Viburnum.—Mr. A. E. BOWLES showed some shoots of *Viburnum Tinus* var. upon which small blisters were developed, which later grew larger until corky growths of considerable size were developed. These were recognised as similar to growths described by Dr. Sorauer under the name of "intumescences" arising from over-turgidity of the tissues, and similar in origin to the warts on Vine leaves, &c.

Curiously-coloured seeds.—Mr. BOWLES also showed seeds of *Ravenala madagascariensis*, the Traveller's Tree, and of *Trichilia indica*. The seeds of the former are of a blue-green colour, and have a metallic lustre, being similar in form and appearance to some of the tropical *Buprestidæ*, and the latter red and black, mocking in appearance some of the *Coccinellidæ*. The marked likeness to these beetles was thought to be possibly connected with the distribution of the seeds by birds, who might be deceived into carrying them some distance before they found their mistake.

Fungus on Oak.—Mr. DOUGLAS showed dead branches from Oak trees in the neighbourhood of Great Bookham covered with a parasitic fungus. Mr. DOUGLAS said that large numbers of Oak branches were being killed by the fungus.

Malformed Cypripedium.—Mr. DOUGLAS also drew attention to a flower of *Cypripedium Dayanum*, in which the dorsal and one of the lateral sepals were coherent, showing a normal flower for comparison with it.

Malformed Cyclamen.—Dr. MASTERS showed a malformed *Cyclamen* flower sent by Mr. Pettigrew, which had an adventitious bud in the axil of one of the sepals, a not uncommon malformation in flowers of the *Cyclamen*.

Lenticels in Laburnum.—Prof. HENSLOW showed a piece of the bark of *Laburnum*, and drew attention to the enormous number of lenticels present in that plant, particularly in the inner bark.

Cabbage in Patagonia.—He also showed a specimen of *Brassica oleracea* collected by Chas. Darwin at Port Desire in Patagonia when on his memorable journey, and others collected on the Kentish coast of the same species. It would be interesting to know how that species came to be growing in Patagonia so long ago.

Cotyledon macrantha (Berger).—A specimen of this fine plant shown by Sir Trevor Lawrence was discussed, and Dr. MASTERS promised to examine it and report further upon it at the next meeting.

Diseased Gladiolus corms.—Some diseased *Gladiolus* corms of the variety *Priniceps*, imported from America in 1905, having the interior partly eaten away and so injured that after lifting the corms rot completely away, were received. Mr. GUSOW reported that he found they were attacked by the fungus *Botrytis para-*

sitica, a common fungus on certain bulbous plants. The flies that had been noticed in the corms had evidently been attracted by the decaying tissues and were feeding upon those.

WINTER-FLOWERING CARNATION.

MARCH 13.—The second exhibition of the above society was held on this date in the Royal Botanic Gardens, Regent's Park. The exhibition was favoured by beautiful weather, and the attendance was satisfactory, although not over large. Several meritorious non-competitive exhibits added to the attractions of the show, the most noteworthy being a beautiful display that contained not a few seedlings of merit and notably an unnamed yellow variety, staged by Mr. BURNETT, Guernsey. Only one novelty was submitted to the Floral Committee, and this was an improved form of the well-known White Lawson, and it was granted a Certificate. The amateurs' classes were very poorly represented. The Guernsey exhibitors were remarkably successful.

The class for a collection of Carnation flowers, occupying a table space measuring 10 feet by 4 feet, and interspersed with suitable decorative plants or foliage, was represented by only one exhibit. This was staged by Mr. S. MORTIMER, Rowledge, Farnham, Surrey, who utilised tall glass vases at the back to display the varieties *Enchantress*, *Harry Fenn* (crimson), *Norway* (white), *Nelson Fisher*, *Victory* (scarlet), *Harlowarden*, &c., and smaller vases at the front, with small Ferns intermingled. This exhibit was awarded the 1st prize.

COLOUR CLASSES.

Classes were provided for varieties of white, blush or light pink, deep pink or rose, crimson, scarlet, and any other colour than those mentioned, or fancy, respectively. In each instance separate prizes were offered for a collection of 36 blooms, and for 18 blooms. Competitors were allowed to compete in both sections provided they staged different varieties.

White.—In the larger class for 36 blooms, the best variety was *White Perfection*, shown by Messrs. DODD & LANCASHIRE, Victoria Nurseries, Guernsey. Some of these blooms measured 5 inches across, and the petals were of remarkable purity and of great substance. The 2nd prize went to Mr. DUTTON's *White Lawson* Improved.

In the smaller class for 18 blooms, the variety *Lady Bountiful* shown by Mr. S. MORTIMER, Rowledge, Farnham, was placed 1st; and the same variety secured the 2nd prize.

Blush or light pink.—Four exhibits were displayed in the larger class, three of the variety *Enchantress*, the other being Mr. H. BURNETT's beautiful flower named after Mrs. H. Burnett, a variety deeper in colour than the well-known *Enchantress* and with less crimped petals. This secured the 1st prize, and another Guernsey firm, Messrs. DODD & LANCASHIRE, were awarded the 2nd prize.

Mr. H. BURNETT also won in the smaller class with magnificent specimens of *Enchantress*.

Deep pink or rose.—Three exhibits of the bright rose-coloured Mrs. T. W. Lawson were seen in the 36 class, Messrs. DODD & LANCASHIRE having the premier vase, and they were followed by Mr. DUTTON.

Messrs. B. & V. HAIG, Castle Hill, Maidenhead, won in the smaller class with the same variety.

Crimson.—Harlowarden and President were the representatives of this shade, the 1st prize going to the former variety, the successful exhibitor being Mr. C. ENGELMAN, Saffron Walden, Messrs. DODD & LANCASHIRE 2nd with President.

In the smaller class Harlowarden again won, and President was again 2nd. These were shown by Messrs. MORTIMER and DUTTON respectively.

Scarlet.—Among three exhibits in the larger class the best was a vase of *Robert Craig* shown by Messrs. DODD & LANCASHIRE. This was a splendid exhibit, the flowers were of magnificent colour, and very large. Mr. ENGELMAN followed with the same variety. Three growers contested in this class, the other variety being *Christmas Eve*.

In the class for 18 flowers of this colour, Mr. DUTTON secured the premier place.

Any other colour or fancy.—Prosperity, a variety of somewhat ragged appearance, having

petals blotched with pink on a white ground, was the only exhibit in the larger class, and this was given the 2nd prize. Mr. MORTIMER secured the 1st prize in the class for 18 blooms with Mrs. M. A. Patten, an American variety of large size, streaked with claret on white.

DECORATIVE CLASSES.

The best vase of Carnations, arranged for decorative effect with any foliage allowed, was staged by Mr. BURNETT, his variety being Mrs. H. Burnett. Quality of flowers was the chief consideration in making the award. Messrs. FELTON & SONS, florists, Hanover Square, London, W., were 2nd with the variety *Fair Maid*.

The last-named firm was awarded the 1st prize for a basket of Carnations, having the beautiful *Scarlet Britannia* in a basket with very tall handles that were decorated with the flower to the top.

NON-COMPETITIVE EXHIBITS.

Messrs. HUGH LOW & Co., Bush Hill Park, Enfield, staged a very large group of Carnations, and a miscellaneous collection of greenhouse flowering plants. (Gold Medal.)

Mr. A. SMITH, Enfield Highway, London, N., showed a fine batch of his scarlet seedling *Britannia*. (Gold Medal.)

Mr. E. ENGELMAN, Saffron Walden, Essex, displayed vases of cut Carnations of excellent quality. (Large Silver-Gilt Medal.)

The group exhibited by Mr. H. BURNETT, St. Margaret's Vineries, Guernsey, was an object of great interest. (Large Gold Medal.)

Messrs. W. CUTBUSH & SONS, Highgate, London, N., put up a very pleasing group of Carnations. (Large Silver Medal.)

Messrs. T. S. WARE, LTD., Ware's Nursery, Feltham, showed Carnations. (Silver-Gilt Medal.)

Messrs. WM. PAUL & SON, Waltham Cross, Herts, displayed a fine group of Camellias in the large conservatory. (Gold Medal.)

Mr. W. E. WALLACE, Eaton Bray, Dunstable, showed *Roses Liberty* and *Richmond*.

Messrs. FELTON & SONS, Hanover Square, London, W., displayed floral devices, principally of Carnations. (Large Silver-Gilt Medal.)

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

MARCH 11.—The annual meeting was held on this date. Mr. Charles H. Curtis presided and moved the adoption of the report, which was carried. Mr. W. Collins was unanimously re-elected secretary. On the proposition of Mr. Wm. Marshall, V.M.H., new trustees were elected under the new rules, namely, Messrs. Riley Scott, James Hudson, V.M.H., and Chas. H. Curtis. There were four retiring members of committee, Messrs. Harding, Woods, Thomson, and Curtis; the latter two gentlemen were translated, and out of six nominations the following were elected: Messrs. Harding, Woods, J. Harrison Dick, and Wilson. Mr. Curtis was re-elected chairman of committee, and Mr. T. Winter as vice-chairman.

ROYAL HORTICULTURAL SOCIETY.—At a meeting of the committees to be held on Tuesday next, a lecture on horticulture in British Guiana will be delivered by Mr. J. A. BARBOUR JAMES, at 3 p.m.

THE WEATHER.

THE WEATHER IN WEST HERTS.

Week ending March 15.

Variable temperatures.—On the warmest day the temperature in the thermometer screen rose to 57°, which is the highest reading as yet this year, and on the coldest night the thermometer exposed on the lawn registered 16° of frost. The ground temperatures have varied, and are now slightly below a seasonable temperature, both at 1 and 2 feet deep. Rain, hail, or snow fell on five days, but to the total depth of only half an inch. Small quantities of rain water have percolated each day through the bare soil gauge. The sun shone on an average for 5½ hours a day, which is about the average record for the middle of March. The winds were, as a rule, high, but in no hour did the mean velocity exceed 18 miles—direction W.N.W. There was about a seasonable amount of moisture in the air at 3 o'clock in the afternoon. A selected patch of yellow Crocuses in my garden first showed an open flower on the 10th, which is 15 days later than its average date in the previous 30 years, and later than in any of those years since 1895, or for 12 years. E. M. Berkhamsted, March 13, 1907.

MARKETS.

COVENT GARDEN, March 13.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—Ed.]

REMARKS.—West Indian Bananas are still scarce. Californian Oranges are arriving in larger quantities, consequently prices are lower. There are large supplies of English forced Rhubarb on the market this week. P. L., Covent Garden, Wednesday, March 13, 1907.

POTATOES.

Bedfords, 65s. to 80s.; Blacklands, 65s. to 75s.; Lincolns, 70s. to 95s.; Yorks, 80s. to 100s.; Dunbars, 90s. to 120s.; Teneriffe, 10s. to 12s. cwt. Trade is about normal for the time of year. W. J. C. & S., Covent Garden, March 13, 1907.

COVENT GARDEN FLOWER MARKET.

Trade has brightened a little for some things, but generally business is very quiet. Flowering plants are now of better quality, especially Genistas and Cinerarias, but the latter plants have depreciated in value, for they are now plentifully arriving from several of the best growers. Cyclamen are also abundant, and though well flowered, they do not make good prices. Callas in pots are seen in fine condition, but there is little demand for them just now. Best Liliums in pots are not abundant, and most of the plants seen are rather tall. The flowers of L. rubrum are of a pale colour. Lily of the Valley is remarkably fine in pots, and Messrs. Rochford and Sons are sending pretty specimens in zinc-lined baskets. Begonia Gloire de Lorraine in hanging baskets are also very pretty. These Begonias in pots are scarcely as good as they were earlier in the season. Daffodils in pots are very good; these plants are now grown more naturally and without so much heat as when they were first placed on the market. Indian Azaleas are now at their best, and beautifully flowered plants are seen, but supplies are excessive, and it is difficult to clear stocks even at reduced prices. Erica Wilmoreana is very fine from several growers, but the variety Superba from Mr. Sweet is specially worthy of note. Persoluta alba is also remarkably good. Acacia Drummondii and A. ovata are seen in well-flowered plants. Boronia megas-

tigma is also now in the best condition; the yellow variety is very pretty. Marguerites are plentiful. Ferns are well supplied. In Palms there are some clean, healthy young plants in 60-size pots, which are sold cheaply. Best plants of Aralia Sieboldi in various sizes sell fairly well, but some have very tender young leaves. Mignonette was noticed, but it was not of high quality.

CUT FLOWERS.

This morning (Wednesday) I find there is a great drop in the cut flower trade, and the above price list must not be taken as absolute in all cases, for one of the leading salesmen informed me that he was glad to accept any offers to clear his consignment. Daffodils are the leading feature, and these have dropped considerably in prices; very fine samples of N. Horsfieldi can be purchased at 3s. to 4s. per dozen bunches, and the variety Henry Irving could be obtained for less. N. Emperor from some English growers is very fine. The importations from the Channel and Scilly Islands and other outside sources depreciate the prices of English grown flowers, which are certainly the best. All Dutch bulbs are abundant; some of the best double Tulips keep up in price, but "singles" are very cheap. Roses are more plentiful, and very fine blooms of Caroline Testout can be had at about 4s. per dozen. The red varieties are also much cheaper: these include Liberty, General Jacqueminot, and Richmond, the last-named commanding the best prices. Carnations are well supplied; best blooms are valuable, but the majority are cheap, and I noted this morning that many were unsold. Liliums are more plentiful, especially L. lancifolium and L. longiflorum, which are cheaper. Callas were never more abundant. A. H., Covent Garden, Wednesday, March 13, 1907.

DEBATING SOCIETIES.

DEVON AND EXETER GARDENERS'.—At a recent meeting of this association Mr. Andrew Hope, Exeter, read a paper on "Hardy and Half Hardy Annuals." He advocated the digging of the ground in December or January, and leaving it rough to benefit by the rain, frost, and air. Old rotten manure from the stable, cowshed, or piggery was suitable. Great stress was laid upon sowing thinly, as many beds of annuals were rendered spindly, weak, and, in fact, ruined from over-thick sowing. This applied especially to such subjects as Shirley Poppies, Mignonette, Nasturtiums, and Sweet Peas. Among the annuals recommended were Cosmos, which should be sown in February under glass, Coreopsis, Salpiglossis, Hunnemannia, Gaura, Godetias, the annual Wallflowers, Shirley Poppies, French and African Marigolds, and Tom Thumb Antirrhinums. One of the finest and showiest of annuals was Salvia splendens "Lord Pauntleroy." Among the dwarfier growing annuals suitable for the front of borders or for small clumps by themselves were Nasturtiums Lilliput and Queen of Tom Thumbs, Phlox Drummondii nana compacta, Alyssum saxatile compactum, Phacelia campanularia, Marigold—Star of the Legion of Honour, Bismarck Mignonette, the Nemesis, and Diascia Barbery. Ricinus, Perilla, and Gypsophila elegans were recommended, the former as a foil to lighter colours and the latter for arranging with Sweet Peas and other flowers. Mr. Sidney Baker, of Wear House Gardens, presided, and there was a large attendance of the members.

CHESHIRE PATXON.—Hardy fruit culture was the subject of discussion at the meeting of the above society, held on Saturday, March 1. Mr. J. Riddell, of Messrs. Dickson's, Ltd., introduced the subject and gave valuable hints as to the best methods of planting, the necessary artificial manures for finishing and colouring Apples, Pears, &c. In advocating "ringing" or "barking" of Apple and Pear trees as a partial substitute for root pruning the lecturer was out of sympathy with the opinion of the majority of his audience. An interesting discussion followed.

READING AND DISTRICT GARDENERS'.—Two meetings in connection with this Association have been held during February. The first took place in the club room on the 11th, when Mr. H. Wynn, The Gardens, East Thorpe, gave a paper on "Some Useful Winter-Flowering Plants." Of the many useful flowering plants for winter Mr. Wynn elected to deal with three only, viz., Gloire de Lorraine Begonia, Cyclamen and Cineraria. A good discussion followed. On the 25th the members assembled in the Abbey Hall to hear Mr. F. B. Parfitt, of Elmcoft, Caversham, relate, "How I Started My Fruit Plantation." The lecturer during the recent dry summer used no fewer than 100 loads of manure for mulching purposes, and 750 tons of water for keeping his trees in good growing condition, a statement that surprised many of his audience. A feature of the meeting was a display of 58 distinct varieties of Apples, made by Mr. T. J. Powell, gardener to Mrs. Noble, of Park Place, Henley-on-Thames.

SALISBURY AND DISTRICT GARDENERS'.—Although this society was started as recently as the beginning of October last it has 180 members, and its weekly meetings are well attended. On February 27 a large audience listened to a lecture delivered by Mr. John Smith, of Messrs. Keynes, Williams & Co., subject, "How Plants Live." The lecturer was assisted by a lime-light lantern and slides. A short discussion followed. E. R.

DORCHESTER GARDENERS'.—A special meeting of the above society was held at Ermington House on Wednesday, February 27. A lecture, illustrated by lantern slides, on "Primula sinensis," was given by Mr. H. G. Cox, hon. sec. of the Reading Gardeners' Society. The President (Captain R. Dymond) was in the chair. Mr. Cox traced the development of this flower from the time it was introduced into this country from China in 1819 until the present time. The lecturer also described and showed on the screen Primula obconica and its varieties, and Primula japonica.

BRISTOL AND DISTRICT GARDENERS'.—A meeting of this association was held at St. John's Parish Room, Redland, on March 7. Mr. Curtis presiding. Mr. Turnham, a member of the Reading Gardeners' Association, gave a lecture on trenching and sub-soils. Mr. Turnham illustrated his remarks by the aid of a very cleverly designed diagram. J. P. Bruce.

WARGRAVE AND DISTRICT GARDENERS.—At the meeting of this association, held on March 6, Mr. W. H. Scott, Gardener to Capt. Coleridge, the Hermitage, Twyford, read a paper on "Plants Suitable for Bog and Water Gardens." The lecturer gave details for the arrangement and construction of a bog and water garden, and explained the necessity of a constant supply of fresh water. Weeds must be rigorously excluded and plenty of room allowed the permanent occupants. The best subjects for planting in bogs, lakes, and ponds, and on their margins were mentioned, and the proper method of planting them described.

SEVENOAKS GARDENERS.—At a recent meeting of this society Mr. H. Cannell delivered a lecture on "Pruning and Cleaning Trees, and Preserving Fruit." To obtain the best results from fruit trees, they must have constant care in pruning, but all kinds could not be treated alike. In the case of vines, he favoured the "extension" system of pruning. This method of culture was adopted with the celebrated vines at Hampton Court and at Cumberland Lodge, Windsor, and was, no doubt, the secret of their long life and vigour. Besides being pruned, fruit trees must be kept clean by spraying with a suitable wash. Mr. Cannell gave the recipe of a simple method of preserving fruit, and showed a specimen bottle of Plums that had been preserved for nearly two years.

BECKENHAM HORTICULTURAL.—At the meeting held on the 1st inst., Mr. Mark Webster, of Kelsey Park gardens, gave a paper entitled "Cropping the Kitchen Garden or Allotment to Obtain a Constant Supply of Vegetables." Councillor Moss presided over a large audience. A brisk discussion ensued after the reading of the paper. T. C.

REDHILL, REIGATE, AND DISTRICT GARDENERS.—At the meeting of the above association held on Tuesday, March 6, Mr. G. Grace gave a lecture on "Flower Fertilisation and Insects." Mr. F. C. Legge occupied the chair. The lecturer showed how pollination was effected by various insects, and especially by the bee. A large number of lantern slides was displayed showing the essential organs of the flower, how they are situated, and the means by which fertilisation is effected. After the lecture a number of other lantern slides were thrown upon the screen, including pictures of local views and residences.

CROYDON & DISTRICT HORTICULTURAL.—Mr. M. E. Mills, Coombe House Gardens, Croydon, gave a very interesting "talk" on "Herbaceous Borders," before the members of the above society on Tuesday, March 6. In forming the border it is necessary to trench deeply, bringing the subsoil to the top, providing this be of a loamy character, and adding well-rotted manure. As each plant may require special compost to flourish in, the border should be made up accordingly. Always mingle the plants so that the colours of their flowers will harmonise.

Obituary.

GEORGE RICHARD ALLIS.—We regret to record the death of this well-known gardener, whose remains were laid to rest in Kempston cemetery, Bedford, on February 23. Deceased retired from the position of head gardener at Old Warden Park seven years ago, and since that time he had been living quietly at Kempston, at which place he passed away, on February 19, at the age of 79 years. Practically the whole of Mr. Allis's life had been spent in the service of the Ellison and Shuttleworth families. The late Mr. Allis was a successful exhibitor, and often acted as a judge at the principal county flower shows.

JOHN MARSHALL.—We regret to record the death of Mr. John Marshall, head gardener to the Earl of Craven, Coombe Abbey, which took place at Coombe Abbey Gardens on Thursday, March 7, from pneumonia, after a short illness.

ENQUIRIES AND REPLIES.

LEAK IN POND.—Can anyone advise me, or tell me where to get advice as to how I may prevent a pond head from leaking? It is concreted, but is always a source of trouble. The size of the pond is 150 x 25 x 4 feet. *Langdown, Englefield Green, Surrey.*

ANSWERS TO CORRESPONDENTS.

* * * The Editor will be glad to receive, for consideration, large photographs of horticultural subjects, suitable for forming Supplementary Illustrations to this Journal.

APPLE SHOOT: A. L. G. The small red eggs on Apple shoot are apparently those of a species of mite (Bryobia). They are extremely abundant in such situations, but do not cause any serious harm to the trees. Any of the caustic potash solutions will kill them.

ARTISTIC FLOWERS: F. P. The picture is that of *Lapageria alba*, a by no means uncommon

plant which can be purchased from any nurseryman who cultivates greenhouse plants. *Nicholson's Dictionary of Gardening* would be suitable for your purpose.

BEGONIA: A. B. It is a fact that the variety *Agatha* produces more female flowers than are usually produced by *Gloire de Lorraine*. Both varieties have yielded vegetative sports, as distinct from seed sports.

CACTUS. *Needle.* We cannot advise you unless you can give us more exact information.

CORNISH "TRENTHAM" BOILER: H. A. T. A 4-inch flue space should be provided in the brick setting around the sides and top of the boiler, and a 9-inch space in the flue at the back leading into the chimney will be necessary, avoiding sharp turns in making this connection. We cannot see how you are going to attend properly to your furnace in a stoke-hole measuring only 8 feet by 6 feet, seeing that your boiler will occupy 5 feet of this ground space. Stoking a boiler of this size, capable of heating 1,900 feet of 4-inch piping, cannot be done within a space of 8 feet of the front of the furnace. You cannot possibly use the clinking-bar properly, if at all, within the space indicated. You should have a standing ground space of at least 5 feet in front of the furnace door. A recessed space of 2 feet, and the same width immediately in front of the furnace door, would answer the purpose fairly well as you are so hard pressed for room, and this narrow space will enable the clinking-iron, &c., to be used. We strongly recommend any of our readers who contemplate putting in new heating apparatus to provide ample ground space in the stoke-holes, not only to enable stoking to be done efficiently and comfortably, but also large enough to contain a few days' or weeks' supply of fuel at a time, and to see that safe and easy steps leading down to the said stoke-hole are made when the walls are being built. We prefer the more modern sectional and horizontal tubular boilers mentioned in your note to the one you have chosen, seeing that, in addition to the greater durability and efficiency of the tubular type of boiler as compared with the Cornish boiler, there is a substantial difference on the right side of £22, £16 10s. and £15 respectively in the prices, all the boilers having an approximate heating power of 1,900 feet of 4-inch piping, and all are economical in the consumption of fuel. See answer to *Alpine* in our last week's issue.

LILAC BUDS DESTROYED: *Lilac.* The buds appear to have been injured by birds. Place some cotton among the branches, and put up a scarecrow to frighten the birds away.

MARGUERITE LEAF MINER: F. H. The eggs are deposited in the leaf by a fly, which punctures the epidermis, or skin, and lays the eggs in the tissue of the leaf. The grubs hatch later and tunnel in the leaf, but they do not travel from one leaf to another. Later the grubs develop into the perfect insect. The best plan is to pick off the badly affected leaves and to burn them, and in the case of those leaves with a few of the insects only, to crush the grubs between the finger and thumb. Spray the plants with quassia extract occasionally, a substance distasteful to the fly. See illustration in the *Calendar of Garden Operations* to be obtained from our publishing department, price 7d. post free.

MUSHROOMS IN MEADOW: S. W. You might insert the spawn at any time in June, preferably during showery weather. If you lift squares of turf and remove sufficient soil from under these to allow of a forkful of manure being substituted for the soil, a piece of spawn may be inserted in the manure which, having been made firm, should be covered by the lifted turf and made level. Such manure should be properly prepared as if for making a Mushroom bed, and used only when in the proper condition for spawning.

NARCISSUS BULB: A. D. The grub of the Narcissus fly (*Merodon*) too common. Burn the affected bulbs.

PEAR TREE: R. T. The tree is evidently badly affected with canker caused by *Nectria*. Branches as badly infested as those sent seldom bear fruit, as the necessary food cannot reach the buds. A fresh tree would be the best way out of the difficulty. Bad drainage favours the development of canker.

NAMES OF FLOWERS, FRUITS AND PLANTS.—We are anxious to oblige correspondents as far as we consistently can, but they must bear in mind that it is no part of our duty to our subscribers to name either flowers or fruits. Such work entails considerable outlay, both of time and money, and cannot be allowed to disorganise the preparations for the weekly issue, or to encroach upon time required for the conduct of the paper. Correspondents should never send more than six plants or fruits at one time: they should be very careful to pack and label them properly, to give every information as to the county the fruits are grown in, and to send ripe, or nearly ripe, specimens which show the character of the variety. By neglecting these precautions correspondents add greatly to our labour, and run the risk of delay and incorrect determinations. *Correspondents not answered in one issue are requested to be so good as to consult the following number.* **FRUITS:** R. A. Apple Court of Wick.

PLANTS: W. R. R. It is impossible to name with certainty scraps from seedling Conifers, and, of course, without cones. 1, 5, 6, species of *Picea*; 4, *Picea excelsa* var. *Clanbrassilliana*; 2, *Abies Nordmanniana*; 3, *Abies*. We are sorry not to be able to do more for you. Some nursery foreman who has the plants under his eye every day might give you more trustworthy information.—J. R. B. One of the Poplars showing the male catkins. Send when in leaf.—*Northumbrian.* 1, *Odontoglossum pulchellum*; 2, *Dendrobium nobile*; 3, *Juniperus communis* var. *hibernica*; 4, *Juniperus sinensis*; 5, *Cephalotaxus drupacea* var. *fastigiata*.—A. D. 2, *Lopezia coronata*; 1, not recognised.—*Ozonia.* 1, *Cupressus (Retinospora) funebris*; 2, *Alce verrucosa*; 3, *Thunbergia (Meyenia) erecta*.—M. A. W., *Stansted.* 1, *Begonia Ingramsii*; 2, *B. hydrocotylæfolia*; 3, *B. manicata*; 4, *Adiantum Capillus veneris*; 5, *Lastrea lepida*; 6, *Hippastrum aulicum*.—G. E. *Odontoglossum crispum*.—J. D. 1, *Phalaenopsis Schilleriana*; 2, *Duranta Plumieri variegata*; 3, *Ophiopogon japonicus*, *Bot. Mag.*, t. 1, 063; 4, *Sericographis (Jacobinia) Ghiesbreghtiana*; 5, *Sobralia macrantha*; 6, Send when in flower.—H. A. *Hemantus natalensis* and *Ornithogalum lacteum* (the white).—M. G. T. *Broughtonia sanguinea*.

PTERIS FERN: H. L. Though there are no thrips present on the withered fronds received, we believe the injuries to be due to this active little pest. The best means of destroying thrips is to fumigate the house with hydrocyanic acid gas, or failing this, with one of the nicotine vapourising compounds. You might dip the plants into tobacco water, and if the operation is repeated occasionally, the plants will be cleansed. Not having seen your plants we do not exactly know their condition, but if the fronds are greatly disfigured, we should be disposed to cut them all off, and after fresh ones appear, repot the plants and make a fresh start.

ROMAN HYACINTHS: W. S. These cannot be successfully forced for two seasons in succession. Forcing being somewhat expensive it would be wasteful to employ inferior bulbs for such treatment. Even if planted out-of-doors Roman Hyacinths are not a permanent success in this country unless in selected spots in the most favoured situations.

TOMATOS: C. W. The seedling plants are attacked by what is known as the "damping off" fungus, *Pythium de Baryanum*. The cure for this consists in lessening the water supply to the roots and by exposing the plants to the sun's rays, taking care also to admit as much fresh air into the structure as may safely be done.

VINE SHOOT: A. S. We can find no trace of fungus disease or of insects. The only cause which we can assign, from the appearance of the shoots, is excessive treatment with artificial manures. We have seen that over-watering with liquid manure will produce this result.

WAGES FOR GARDENERS IN SOUTH AFRICA. *April.* In our issue for February 27, 1904, p. 138, a letter from a resident gardener in South Africa, who advises no person to accept a lower salary than £3 to £3 10s. per week, and on no account to sign an agreement for two or three years before going out. He says £2 a week in Africa is scarcely the equivalent in value of £1 at home.

THE PRUNING OF ROSES.

THE operation of Rose-pruning requires the exercise of a considerable amount of professional skill, and it is necessary for the operator to possess an adequate knowledge of the particular varieties he has to prune. Different varieties require different treatment. It is not possible, however, to consider here the peculiarities of each variety. I will therefore speak of types, or classes, and state what pruning I have proved during many years' practice to be productive of the best results. The operator, however, must first decide whether he will so prune as to obtain flowers of the first quality suitable for exhibition, or simply a large quantity of flowers of moderate size and quality for decorative purposes. In the first case much closer pruning will be necessary, and the subsequent flowers will need to be reduced to one on each shoot, but in the latter case the knife need not be so freely used. In any case the sappy, weak and inferior shoots should be removed; they will not produce flowers if allowed to remain, and would only congest the plants with weak, sickly foliage, preventing light and air from duly penetrating to the more vigorous flower-bearing wood. My thoughts turn to a famous Rose border of one-quarter mile

in length with which I had connection 20 years ago. On each side of the drive there was a border 9 feet wide; the back row of Roses were all of a climbing habit, trained up strong stakes, and from these plants to the front plants they graduated, the border having a gradual rise from front to back. The effect at flowering time can perhaps be imagined. A free use of *Lilium auratum* planted in clumps at intervals amongst the Roses continued the display. Since the introduction of so many beautiful Rambler varieties, such a border would now surpass what I have described, which at that time was visited by all the leading rosarians of the day.

Returning to my subject, I may say that I have observed that Roses growing on the Manetti stock do not succeed with such severe pruning as those on the Briar. It is apparently impossible to obtain from cut-back plants such fine exhibition blooms as are staged from maiden-plants.

TIME FOR PRUNING.

The gardener must be guided by the conditions of the weather, and by local circumstances, for no hard and fast rule can be observed in this matter. It is generally considered that when the month of March has arrived it is time to prune; so it may be in some cases, but the observant man will first consider whether there are any circumstances that render it advisable to defer the operation for a week or two longer. Early pruning may have the result of causing many of the earliest and best flowers to be destroyed by cold winds, late frosts, and destructive mildew.

HYBRID PERPETUAL VARIETIES.

As with many other Roses, the weak shoots should have been removed from these in October last, but if this was not done, then remove them now. Shorten the strong shoots made last season to five or six eyes (buds), the more moderate shoots to half that number of buds, and the weakest to one or two eyes. Cut out all the old snags and useless wood, and if there are too many shoots or some that cross with another, thin out the unnecessary shoots, cut back those which cross, and prune so that when the operation is completed the regulated shoots will be equidistant.

HYBRID TEAS AND TEAS.

The end of March will be quite soon enough to commence the pruning of Hybrid Tea-scented varieties. These being, as a rule, of strong, sturdy growth, may be pruned in the same manner as Hybrid Perpetuals.

Tea-scented varieties should be pruned in April. The strongest shoots on dwarf-growing plants should be shortened to about eight eyes, and the medium and weak growths more severely. The climbing varieties of this section will require to have some of the shoots thinned out, and the unripened points of strong shoots cut back. Varieties such as Ards Pillar, Billiard et Barré, François Crousse, Noella Nabonnand, &c., that make vigorous growth, may be treated in a similar way to the climbing sorts.

RAMBLER AND "WICHURAIANA" ROSES.

Taking the popular Crimson Rambler as a type, much of the pruning of such Roses should be done soon after the flowering period is past; the shoots which have flowered may

then be removed entirely, thereby leaving a clear field for the strong, fleshy growths proceeding from the base. I do not consider it good policy to remove too great a number of these shoots at one time, it is better to extend the operations over a period of two or three weeks. Under this section there are such varieties as Aglaia, Blush Rambler, Hélène, Philadelphia Rambler, Psyche, Gruss an Zubern, &c. The Wichuraiana Roses and the hybrids require similar treatment. This section includes such beautiful kinds as Dorothy Perkins, Lady Gay, The Farquhar, Debutante, and many others whose glories are becoming well known. These are so vigorous that they are capable of soon covering a large area. The long, vigorous shoots which were produced from the base during the last season only require to have the soft, unripened tips removed from them. It is very inadvisable to perform this operation before growth is completed in the autumn, for the sake of obtaining order and tidiness, for by so doing, the dormant buds which would produce flowers the following season, commence to grow into weakly side shoots, and only half a crop of flowers is the result.

AUSTRIAN AND OTHER BRIARS, &c.

How often we see the beautiful Austrian Roses denuded of their flowering growth in spring! The deep yellow flowers, and fragrant foliage of the Persian yellow makes this variety one of the worthiest yellow Roses in cultivation. Simply to thin out the weak shoots, and to remove the tips of the strongest of last year's shoots satisfies their present needs. Provence or Cabbage Roses may safely be pruned after this date, cutting out the weakest shoots and pruning the strong and moderately strong shoots back to two or three eyes. This class of Rose, together with the Moss Rose and their hybrids, amply repay for high cultivation. Moss Roses should be divided into two sections: the ordinary Moss Roses and their hybrids, comprising all the strong growers, should be pruned by freely thinning out the weak shoots and shortening the stronger ones about one-fourth their length. The perpetual Moss Roses require much closer pruning. Moss Roses are worthy of a place in every garden, as they furnish good flowers right into the autumn. Hybrid Chinese and Hybrid Bourbons require very similar treatment. As they flower in summer and autumn, preparation is necessary by removing or thinning out in October many of the weak shoots. If this work was not done at that time, it may be done early in April, at the same time shortening the strongest shoots to six buds, and the weaker ones more severely. Varieties such as Blairii No. 2, Carmine Pillar, Madame Plantier, and Fulgens, which are amongst the best pillar Roses, will not require such severe pruning as the others of this section.

Damask Roses, French Gallica or Provins Roses are a very old-fashioned section, the varieties with striped flowers forming conspicuous objects in the Rose garden. The variety Rosa Mundi, more generally known as York and Lancaster, is one of the best; at the end of March prune the strongest shoots to 6 or 8 eyes, and the weaker growths to 3 eyes, thinning out old shoots and useless wood.

The old Maiden's Blush, coming under the Alba Rosa section, so much appreciated before the advent of modern varieties for its extreme

delicacy of colouring, may have last year's shoots pruned to the third or fourth bud from their base.

In respect to the Bankian Roses, all hope of flowering is sometimes destroyed by injudicious pruning; indeed, they require very little pruning. In June, when the plants have flowered, cut out the long, gross shoots, and shorten the tips of those remaining. This Rose requires to be planted against a warm wall, and in a moderately dry border.

Musk-Roses and their hybrids make very rapid growth. They are exquisitely beautiful and free-flowering. Amongst them are Madame d'Arblay, The Garland, &c., each distinguished by the peculiar Musk-like scent. Thin out the shoots freely early in April, and shorten the shoots one-half or one-quarter, according to the space it is necessary to cover with them.

Evergreen Roses, such as *Félicité et Perpétue*, *Myrianthes Rénoncule*, only require to have the

this country and abroad. A short article in *Möller's Deutsche Gärtner Zeitung* for February 23, concerning Herr. F. Sinai's nursery at Frankfort-on-the-Main, emphasises this fact in regard to the Chrysanthemum, the aim being the production of perfect blooms for sale purposes from the beginning of the month of October to the end of the year—therefore three months. For this purpose only those varieties are grown which possess properties and qualities which are best fitted for the end in view—matters that require powers of close observation, good acquaintance with varieties, and acute judgment in forming a correct verdict of the character of a variety. Specialists having these qualifications are enabled to attain results that the more superficially working horticulturist never reaches. Such a specialist is Herr. F. Sinai. In this nursery the propagation of the Chrysanthemum takes place in April and May, in the usual mode

method could the houses be cleared conveniently. Efforts are continually being made to reduce the number of varieties, but the length of the flowering season being from October to December, it is necessary to have a considerable number under cultivation, in order to have sufficient plants of every colour for every week for cutting.

The chief varieties grown are—early in October: Mme. Gustave Henry and Mme. Draps-Dom; end of October: Roi d'Italie, Belle Gascoigne, W. Seward; beginning of November: Miss Alice Byron, Mlle. Clementine Touzet, Master W. Tucker, Miss L. Cheeseman, Mermaid, La Gracieuse; end of November: Princesse Basaraba de Brancovan, Sappho, W. Duckham, Satin rose, Mm^e. Philippe Rivoire, Western King; beginning of December: Oceana, Sunstone, Mme. Paolo Radaelli; Christmas: Mme. M. Th. Charvet and Mme. Calvat. Herr. Sinai grows 15,000 of these single-bloomed plants. F. M.

ROSS NONPAREIL.

To Mr. Baylor Hartland, Arn Cairn Nurseries, Cork, we are indebted for specimens of what he describes as the true Ross Nonpareil. The fruits are rather more than 2 inches in length, and about the same, or rather more, in breadth; subglobose, slightly depressed at the top, with a small, shallow eye and short tube with marginal stamens and infolded segments. Stalk half-inch, in a deep depression. Skin golden-brown, streaked with crimson. Flesh firm, yellowish; carpels oblong pointed. Flavour brisk, acidulous, excellent for the season.

THE STERILISATION OF SOIL.

(Concluded from page 152.)

STEAMING.

Steaming may be effected from either above or from below. When from above the steam is forced into the soil by means of what is termed a steriliser, an apparatus consisting of a hollow frame, measuring 5 by 2½ feet, constructed of steam pipes, with prongs, hollow and 10 inches in length, pointed and perforated to allow the steam to pass into the soil. The parts are covered with a light metal cover, which prevents steam from passing out of the soil. The ground should be fairly open when it is steamed, and, if hard, loosened by forking it over. The prongs are thrust into the soil by pressing the apparatus downwards; the steam is turned on when the pressure is at from 40 to 50 lb. per square inch, and the soil is steamed to a depth of 9 inches, more or less, in from two to three minutes. The portion of the soil covered by the steriliser is brought to a temperature of 180° to 212° Fahr. or more, when the steam is turned off at the generator while the steriliser is removed to a fresh place. About 1,800 square feet or 200 square yards are usually sterilised in a day with one steriliser at a cost of about £1 for fuel and labour, the soil being sterilised *in situ*, as in a Cucumber or Tomato house, or even outdoors.

Steaming from below is effected by means of a system of perforated iron or galvanised iron pipes, 2 inches in diameter, with ¼-inch perforations about 1 inch apart. The framework of pipes is laid on the surface of the ground or on a floor, and the soil to be sterilised is placed on the framework to the depth of 1 foot. The steam is passed through the pipes at a pressure of about 30 lb. to the inch for 1 to 1½ hours. In the case of the framework being laid on soil, and soil from the sides of the bed placed on to the depth of 1 foot, it follows that the soil below, as well as above the pipes, will be sterilised. The cost of this mode of sterilisation is about 30s. per 1,000 cubic feet of soil, calculating that below as well as that above the steam pipes or steriliser.

FIG. 80.—APPLE ROSS NONPAREIL.

small shoots thinned out, and the tips removed from the stronger ones. This form of Rose, grown as weepers on tall standards, form perfect masses of bloom, and in such cases the "head" should be kept well thinned. By regulating the length of pruning, flowers will be produced from base to summit. W. H. Clarke, Aston Rowant, Oxon.

(To be continued.)

CHRYSANTHEMUMS FOR CUT BLOOMS.

As may be readily understood, the success of the specialist in any branch of cultivation must greatly exceed that of the cultivator of many species, whether for market purposes or otherwise. This fact is apparent on every side, and in particular in Chrysanthemum culture in

and when the cuttings are rooted singly in small pots, they are planted out in the then empty Lilac houses, from which, as soon as they have taken root, the lights are removed, so that throughout the summer the plants stand in the open air, and the usual round of affording water, stirring the surface of the soil, syringing, the fight with injurious insects and fungus plant-pests, and the nipping off of superfluous flower buds and shoots carried out, so as to obtain the best possible results; and on each plant only one flower is allowed to remain. Seeing that the earliest house must be emptied in readiness for Lilac forcing by the middle of October, and all the other houses in rotation up to the end of the year for a similar purpose, Herr. Sinai arranges his plants according to the dates at about which they flower, all such as bloom together being placed together, as only by this

STERILISING BY MEANS OF HOT WATER AND BAKING.

By sterilisation with hot water, only a few inches of surface soil are sufficiently heated to kill nematode worms and fungus pests, any deleterious effects as regards bacteria being confined to the putrefactive species, as they, from their food being mostly located in the surface soil, are most susceptible of injury by scalding the soil. In the case of sterilising by baking, a similar effect is produced as in the case of hot water, though reversely, the outside of the turves on the hot plate not being heated so highly as to prejudice other than the putrefactive micro-organisms.

Sterilisation by steam is almost identical with that by hot water: the surface soil is heated to a high temperature and the putrefactive bacteria are practically killed as well as fungus pests, nematode worms, and insect pests, also weeds and weed seeds.

The putrefactive bacteria, as we have already described, are present everywhere, therefore, if they be destroyed in surfacing soil, or the crust of turfy loam, others will speedily take their place, assuming the organic matter not to have been burned. The remains of vegetation and also of animals will be seized upon and be quickly decomposed, hence we may in a measure account for the good result following scalding, baking, and steaming soil, equal in many cases to manuring. The processes do not affect the soil bacteria, particularly in the case of surface scalding, baking, or steaming, for these organisms are more abundant below the top 9 inches of soil, where they find the necessary bases (lime, potash, and soda), as well as the nitrogenous matter.

EXCESS IN STERILISATION.

There is no doubt, however, that scalding, baking and steaming of soil can be carried too far, and that baking and steaming are the more likely to be disastrous. As an instance I may mention that to a large firm growing Cucumbers very extensively, I advised scalding the walls and floors (with the beds) with boiling water for the destruction of eel-worm, sleepy disease, and leaf-spot, and also for the sterilising of new soil as well as old. Instead of scalding the soil the firm steamed it, and in this steamed soil Cucumber plants would now grow. What degree the heat reached I was unable to ascertain, beyond that it was considerably above 212°, and it is certain that the soil was to all intents and purposes intensely sterilised, which, in its strict sense, implies removal of nitrogen and consequent barrenness.

Cultural sterilisation requires no great heat in respect of freeing soil from pests. Animals—Vermes, Mollusca, Crustacea, Arachnida, Myriopoda, and Insecta, succumb to a temperature of 125° Fahr., and most, if not all, fungus pests perish in a heat of 130° to 135° Fahr., so that there is no need to heat soil to over 140° to 160° Fahr., the temperature at which the fermentative bacteria thrive, in order to destroy the ground pests of useful crops. The high temperature of steam, always over 212° Fahr., renders it somewhat dangerous to use for fear of destroying the useful micro-organisms as well as the parasitic bodies, but when used judiciously, and not so as to heat the soil above 180° Fahr., it is perhaps the best means for effecting cultural sterilisation. G. A.

THE FERNERY.

HARDY FERNS IN SPRING.

At the outset we may say that the hardy Ferns we have mainly in view are those beautiful varieties of our native Ferns which so far excel the normal forms in beauty and diversity of form as to be infinitely preferable to them for garden-culture or the decoration of cool or cold conservatories. In towns and cities where

houses lie at little or no distance from each other, and many conservatories and parts of gardens are therefore deprived of sunshine to a large extent, we have precisely those conditions which are antagonistic to the satisfactory cultivation of flowering plants and yet peculiarly favourable to that of shade-loving Ferns, and in all such positions a collection of choice varieties cannot be too strongly recommended. It should be borne in mind that these varieties being the direct descendants of the common forms, regarded by the connoisseur usually as weed forms, are perfectly hardy, and so far as living goes will thrive wherever the common ones can do so. Many of them, however, are of such delicate make that they naturally cannot develop and display their peculiar charms if exposed to the dwarfing effects of hot sunshine and wind. Naturally, too, even the common types we find to assume far finer proportions and greater beauty in shady lanes and secluded glens than by the roadside or on exposed moors and hillsides, and the Fern paradises of the world are invariably found in tree-shaded ravines and hollows where not only is the bulk of the sunshine excluded, but, as a rule, hardly a breeze penetrates.

It is under such conditions that Tree Ferns form forests, and the ground is thickly clothed with a luxuriant undergrowth of numerous other Fern species. In this country, with its more or less defined seasons of summer and winter, most of the indigenous Ferns are deciduous, the fronds dying down in the autumn, but a number are evergreen, and under favourable conditions maintain their fronds in fair condition throughout the winter, only dying down when the new spring growth is well in evidence, and by its vigour monopolises the energy of the plants at the expense of the old foliage. Whether deciduous or evergreen, however, there is a long period of rest, extending from October to March, and as this rest is an essential to their well-being, a really warm conservatory is less beneficial than a quite cold one, though one from which the frost is fairly well excluded, keeps the evergreens, which do service in the winter, from becoming as shabby as they will do if frozen hard from time to time.

In March, although there is no obvious growth, the root action certainly commences, and it is precisely at this period that the plants can be handled to the best advantage as regards re-planting, re-potting, dividing, and so on. The long rest gives them a vigour which practically nullifies the effects of shifting and dividing, and enables the Ferns to establish themselves immediately in their new quarters; while the fact that there are no fronds to damage in the deciduous kinds, while those of the evergreen habit, if damaged, will soon be replaced is, of course, a great advantage. These remarks apply naturally to all hardy Ferns, even the exotics, such as *Struthiopteris*, *Adiantum pedatum*, *Onoclea sensibilis*, and others, which have been introduced and are fully as hardy as the native forms. As regards re-planting and re-potting this is not advisable if the Ferns are in good condition and good form as regards specimen plants, but some species such as the *Lastreas*, *L. filix mas*, *L. dilatata*, *L. montana*, and *L. amula*, and the Lady Fern, which send up their fronds in circlets, shuttlecock fashion, round a central crown, have a habit of forming lateral offsets by buds, which in time assume adult size and transform the original single crown into a bunch of smaller ones, due to competition for light and air and root room between the numerous individuals. This, in the varietal form, detracts materially from their beauty, and prevents the individual crown from developing its full character, which is dependent upon full growth.

The fronds, too, naturally intermingle, and in this way the symmetrical grace of the plant is entirely lost. It is well, therefore, whether the specimens be in a pot or in the ground, to

turn them out or dig them bodily up, and take the adventitious crowns away, replanting them elsewhere. This is an easy task, as each crown forms its own set of roots and fronds, and can, as a rule, be pulled away with facility from the central crown, taking care during the operation not to pinch the crown, which at this time contains within itself the undeveloped fronds of the coming season. When these are removed, the central crown will send up its circlet of fronds with far greater vigour, and display its full charm when fully grown. This applies to all crown-forming Ferns, but not to those whose rootstocks travel, such as the *Polypodies*, *Cystopteris montana*, *Pteris aquilina*, *Adiantum capillus veneris*, *A. pedatum*, &c. In these the fronds rise separately in a continued row or rows when the rootstock branches, as is invariably the case.

Once established, all these are best left alone, as the fact that they do travel remedies the evil of crowding above alluded to. If it be desired to divide them for propagative purposes, short lengths of the rootstock, severed with a growing tip, a frond or two, and as much root as possible, will soon establish themselves if planted, preferably in pans instead of pots, to give them more room. A good compost for Ferns generally is a mixture of good loam and leaf-mould, in about equal parts, not sifted, but rather lumpy, and a liberal dash of coarse silver sand. Pots should be well drained, and should not stand in saucers constantly filled with water; a large saucer, with a smaller one inverted in it, upon which the pot is stood above the water surface, may, however, be kept filled, with advantage to most species, stagnation being thus avoided, as well as drought. Sankey's well pots, with a hole in the side an inch from the bottom, and a perforated diaphragm an inch above the hole, are also extremely good for Ferns, and obviate greatly the risk of drought by always retaining a little water in the bottom of the pots. In the open, good garden soil suits hardy Ferns very well, but it is beneficial to add a little of the above compost when planting out offsets obtained by division, and to see that water is supplied if drying winds set in before they are established. The Shield Ferns (*Polystichum*) are not so much addicted to forming adventitious lateral crowns, but a number of them form buds near the base, or even all the way up their fronds, and these should be collected for propagation purposes when the old fronds are being removed later on in the season. It is not wise to remove fronds which are still green, as it impoverishes the plant. Chas. T. Druery, V.M.H.; F.L.S.

PLANT NOTES.

ROMULEA PYLEA.

I RECEIVED bulbs of this little plant from Mr. Archer-Hind four years ago. He informed me that it had appeared in his garden among some other bulbs that he had obtained, its identity being evidently unknown to the sender. He said that it was very rare and practically not in cultivation. Certainly, I have never seen it in any garden but his. Mine have thriven well and increased, and a couple of dozen flowers are generally produced in March. The first of the year opened on the 11th inst. It is a pretty flower, pure white with a golden throat and 2 inches across when expanded in the sunshine. When twenty or more blossoms are fully open on a sunny morning, the clump, with its thin, rush-like foliage, is a pretty sight. The species is not mentioned in any horticultural dictionary that I possess. Another *Romulea* that will be open in a day or two is *R. nivalis*, also not alluded to in the dictionaries. The flowers of this are white, shaded with blue. *R. speciosa* is later with me and is showing no sign of flower as yet. S. W. Fitzherbert. [Both species are included in the *Index Kewensis*, but the names have also been given to forms of *R. Bulbocodium*.—ED.]

FASTIGIATE TREES.

(Continued from page 150.)

DECIDUOUS VARIETIES.

POPULUS NIGRA PYRAMIDALIS (*P. fastigiata*, the Lombardy Poplar).—At the present time this Poplar is by far the most common of fastigate trees. It was introduced from Italy about 150 years ago, and is now as well known as any of our native trees. It grows to 120 feet or even 150 feet high, and its great height and slender form cause it to generally dominate the vegetation with which it is associated. In combination with round-headed trees, and planted with proper restraint, it is most effective. (See supplementary illustration.) Avenues within the garden made of this tree are also very stately and impressive; a good example of its use in this way may be seen at Aldenham House, Elstree. It is not suitable for planting in groups of more than three to five, and the worst possible way of planting it is in solid blocks of a score or more trees without anything else to relieve it. In places where scenic effect cannot be considered, and where a block or screen of vegetation is wanted quickly, such as is often the case in suburban residences where lofty and unsightly buildings have sprung up close at hand, no tree is better than the Lombardy Poplar, although its ally, the fastigate form of the White Poplar, may also be used for the sake of variety. For this purpose both these trees have to be planted thickly, so thickly that they will almost touch when they get to full size.

For a long time only male plants of the Lombardy Poplar were known in this country, but there have been added to the Kew collection in recent years both female and hermaphrodite ones.

POPULUS ALBA PYRAMIDALIS (*P. Bolleana* of gardens).—Very like the Lombardy Poplar in habit (although rather wider in proportion to its height), this tree is, of course, easily recognised in winter by its pale smooth bark and, in summer, also by its leaves being hoary white beneath. It does not grow so fast as the Lombardy.

CARPINUS BETULUS COLUMNARIS.—The Hornbeam is naturally a tree with pendulous, rather Birch-like twigs, but this variety has its branches very erect, thus forming a slender spire-like tree, very striking and elegant. A similar variety of Hornbeam, although not quite so slender in form, is called *pyramidalis*. Dr. Masters has recently called attention to a fine specimen of this tree growing in the Solferino square at Rouen. [The tree is supposed to be some 30 feet or more in height and even more in width, in form like a gigantic Irish Yew.—ED.]

LIRIODENDRON TULIPIFERA FASTIGIATA.—As a rule the upright Tulip-tree as seen in Britain is not particularly striking, but this, I believe, is because most or all of the trees are young, and not in character. In the old-established nurseries of Messrs. Simon-Louis, at Metz, there is a fine specimen of this variety whose cylindrical habit and boldly cut foliage attract one's notice immediately. According to my recollection, it is 30 feet or so high.

CRATÆGUS OXYACANTHA STRICTA.—The foliage and flowers of this tree are identical with those of the common Hawthorn, in fact it does not differ from it except in habit. Whilst not so markedly fastigate as the Lombardy Poplar, for instance, it is still very erect-growing, and on the whole one of the most distinct of the many varieties of the Hawthorn.

PYRUS PINNATIFIDA FASTIGIATA.—*Pyrus pinnatifida* is grouped with the Whitebeam-trees, or "Aria" section of the genus. It is, however, distinguished by its leaves being very deeply cut, and it thus becomes a connecting link between the simple-leaved Whitebeam-trees and the pinnate-leaved "Sorbus," or Mountain Ash section. The fastigate variety is a very hand-

beautiful. It often assumes a rather erect mode of branching, especially when young, but in this variety this characteristic is more strongly marked—and permanent. [A good town tree as seen in some parts of Germany.—ED.]

PTELEA TRIFOLIATA FASTIGIATA.—The "Hop Tree" in even its typical form is not partic-

FIG. 81.—CRATÆGUS OXYACANTHA VAR. STRICTA.

some tree, flowering and fruiting with all the freedom of the group to which it belongs (see fig. 82).

PYRUS AUCUPARIA FASTIGIATA.—In all its forms the Mountain Ash is a very attractive tree, for its leaves, flowers and fruit are all

largely well known in this country. It is a North American tree or large shrub, and is chiefly noteworthy for the clusters of numerous flat circular fruits it bears in autumn, which have a bitter, Hop-like taste. This variety only differs in its erect habit. [One of the finest

specimens of the type was once in Printing House Square near the *Times* office!—Ed.]

ÆSCULUS HIPPOCASTANUM PYRAMIDALIS.—I only know this tree in a small state—about 20 feet high. Its branches grow at an angle of about 45°, and give to it a distinctly pyramidal shape. Where Horse Chestnuts are desired for street planting or narrow avenues it may prove useful.

KEW NOTES.

THE ALPINE HOUSE.

AFTER having been retarded for a long period, owing to the recent spell of cold weather, many beautiful and interesting plants were recently in full flower in the Alpine house. Among the most conspicuous are the following species, &c.:—

flowers, varying in colour to almost white. *C. ibericum* has been in flower since the end of January. A little later in coming into flower is *C. coum*, which differs from the above in having its dark-green, round leaves unspotted. The buds are in evidence long before the bright crimson flowers are fully expanded, the flower-stalk reclining on the surface of the soil until such time as the flower opens, when it slowly raises itself. Although both these species are hardy in the open border, they are seen to better advantage when cultivated in pans in a cold frame and flowered under cover of a cold house.

Scolioptus Bigelovii is a native of California. It is a rare plant of bulbous habit, and the broad, mottled leaves are similar to those of an *Erythronium*. Several flowers are produced in succession from each bulb, each on single stems. They have a somewhat unpleasant odour, while in colour they are green with chocolate markings. While not a showy plant, it is worth growing on account of its earliness and interesting appearance.

Leontice Alberti is a member of the Barberry family from Turkestan, with much divided glaucous foliage, and clusters of yellow and reddish brown flowers. Also in flower is *L. altaica*, a similar plant, but with clear yellow blooms.

*Iris*es are well represented by several species, including *I. stenophylla* with its bright blue-purple flowers with dark velvety blotches on the falls; *I. Tauri*, with flowers of a deeper red-purple shade, but of similar habit and appearance, in fact intermediate forms may be seen that connect the two; *I. Danfordiae*, the charming little species with rich yellow flowers; and the ever-welcome *I. reticulata* with its variety *histrioides*.

Saxifragas are also much in evidence with *S. Grisebachii* showing its crimson stems and flowers, while another red-flowered one is *S. media*. Of those having yellow flowers, there is *S. apiculata*, *S. Boydii*, and *S. Kotschyi*; white being represented by *S. scardica* and *S. Burseriana*, the last-named in the form of *S. Burseriana* var. *major* is one of the earliest of our spring flowers to unfold its buds, and is unsurpassed in beauty by any other member of this genus. In size of flowers this species varies to a great extent, some forms having much smaller flowers than the one above-mentioned. The purple-flowered set is represented by *S. oppositifolia*.

Adonis amurensis is fast becoming a general favourite, with its handsome, finely-cut foliage and yellow flowers. While these are not so large as those of *A. vernalis*, they are produced very early in the year, often in the middle of February. It is in full beauty in the rock garden. The double form, with its green centre, is a most interesting plant.

Miscellaneous.—Among others worth mention is *Fritillaria Sewerzowi*, a native of Turkestan, growing about 1 foot high, with broad, glaucous foliage and bell-shaped flowers of a greenish-yellow shade, having chocolate-coloured markings on the outside of the segments. *Colchicum crociflorum*, from the same country, with its Crocus-like flowers of white variously marked on the outside with reddish-purple, produced five to nine on each bulb; and the various Crocuses, of which the best are *C. Sieberi*, *C. biflorus*, and its variety *Weldenii*, of which there are two forms, one pure white, while the other is flushed with Lilac on the outside. *W. J.*

PLANT PORTRAITS.

AZALEA PERLE DE LOOCHRISTI.—Double white, with larger flowers than those of *Deutsche Perle*, but less regular in form. It was a sport from that well-known variety.—*Revue de l'Horticulture Belge*, March 1.

ROSE MRS. PETER BLAIR.—H.T., pale lemon-coloured flowers.—*Garden*, March 2.

ROSE GOTTFRIED KELLER (lutea var.).—*Rosen Zeitung*, February.

ROSE M'DME. ALFRED CARRIERE.—Noisette hybrid, pale yellow.—*Rosen Zeitung*, February.

FIG. 82.—PYRUS PINNATIFIDA VAR. FASTIGIATA.

(For text see page 184.)

ARALIA CHINENSIS PYRAMIDALIS.—This variety was sent out by Messrs. Barbier, of Orleans, a few years ago. The branches of the species itself are erect, but this variety is curious and distinct because of the large compound leaves also being erect. *W. J. Bean*.

(To be continued.)

Cyclamen ibericum, with an abundance of rosy-purple flowers, which have a dark blotch at the base of the recurved segments. The heart-shaped leaves of this Caucasian plant vary a great deal in the marbling of the upper surface, but usually have a well-defined zone. *C. Atkinsi* is a form of this with somewhat larger

The Week's Work.

PLANTS UNDER GLASS.

By J. G. WESTON, Gardener to H. J. KING, Esq.,
Eastwell Park, Kent.

Medinilla magnifica.—This handsome stove shrub is worthy a place where sufficient room can be devoted to it, and though small plants look very well, it is only when they are fully developed that the species is seen at its best. Plants in pots may now be given a liberal shift, using lumpy loam and peat. Afford plenty of drainage material, as copious supplies of water will be necessary in the growing season. Place the plants in a light position in the stove, shading them during the hottest part of the day only, as the growth needs to be well "ripened" in the autumn. Syringe freely to prevent insect pests, and after growth is complete reduce the amount of water at the root, applying only sufficient to keep the foliage green and firm. The plant needs an atmospheric temperature of 60° in winter.

Cissus discolor.—Cuttings of this charming stove climber will root readily at this season if the young shoots are taken off and placed in the propagating frame in a brisk heat. When rooted, remove them towards the light and pot them as required. They will soon make good plants, either for growing on to become specimen plants or to train on wires under the roof glass. The lateral growths also are very beautiful and of value for decorative work of all kinds. A plant may also be cultivated in a hanging basket. *C. discolor* should be shaded from direct sunshine, or the delicate foliage will soon lose their brilliancy.

Fittonias, Zebrinas, &c.—Propagate from the young growths of *Fittonias*, *Pileas*, trailing *Zebrinas* (*Tradescantias*), putting the cuttings into 3 or 4 inch pots or shallow pans, which may then be used for furnishing the edges of stages in stoves and warm plant houses. Such plants associate well with *Selaginellas*, *Panicum variegatum*, and *Ficus stipulata* (repens). Continue to propagate small batches of this class of plants throughout the season, fresh young plants being always needed for decorative work.

General remarks.—Seedling plants of all kinds should be attended to as soon as they are fit to be handled, this being most necessary to prevent them being drawn in the seed-pans. *Gloxinias*, *Begonias*, *Petunias*, and *Lobelias* will all require attention, pricking them out into pans of light, sandy soil and shading them for a few days if there is bright sunshine, but keeping them always in a light position. More moisture must now be maintained in the stove, by damping down all dry surfaces several times daily, and syringing thoroughly overhead when closing the structure in the afternoon. Such treatment is the best preventive of thrips, red spider, and other insect pests.

THE HARDY FRUIT GARDEN.

By J. MAYNE, Gardener to the Hon. MARK ROLLE,
Bilton, East Devon.

Grafting.—The condition of the trees must be the guide to determine when to perform this work. In favoured spots trees will be ready for this operation now, but in others it must be deferred for perhaps a month. It will be a waste of labour to re-graft other than healthy, robust trees. The usual practice is to "head back" early in the year trees that are to be grafted, but they may be cut back now and grafted immediately with just as much success. Leave a small branch or two, or a little spray wood on well-established trees, to assist the flow of the sap.

Cleft or wedge-grafting is usually practised on stocks over 2 inches in diameter, and I have successfully grafted branches 3 inches in thickness by merely slitting down the bark of the stock and cutting the scion in a similar manner as for ordinary cleft grafting. Make a cross and longitudinal cut for this rind-grafting as if to insert a bud, the cut surface of the scion meeting the wood of the stock. In cleft grafting the stock must be opened with a mallet and chisel, and the scion slipped in ere the chisel is removed. Three, or even four, grafts may be inserted in extra large branches.

Tongue or whip-grafting.—This is the kind of grafting usually adopted by nurserymen, and it is a most satisfactory method in the case of stocks that are not much more than an inch in diameter. Remove with a sharp knife, in a slanting direction upwards, a slip of bark and wood from 2 to 3 inches in length from the stock, and make a small notch or cleft quarter of an inch deep at the top, to insert a corresponding tongue made in the scion. The latter must now be prepared by making a cut to correspond with that on the stock, and the tongue to fit in the cleft of the stock and to hold the graft in position. The scion should be from 6 to 9 inches in length, and bear from two to four healthy buds, according to the degree of vigour in the stock. It is absolutely necessary that the bark of the stock and of the scion be brought into direct contact at least on one side. Clean, smooth cuts are essential on both stock and scion, and they should be made to correspond one with the other as nearly as possible: no dirt or soil must be allowed between the union of stock and scion. Last season's growths furnish the best grafts, although two-year-old wood can be successfully used, and they should be covered with damp moss while preparing the stock, &c. Broad straps of raffia are very suitable for tying the scions when in position, and they need to

FIG. 83.

CLEFT OR
RIND GRAFTING.

TONGUE OR
WHIP GRAFTING.

be bound moderately firm, but not so tight as to damage the bark. No air must be allowed to reach the grafted parts until a union has been effected, and, to exclude it, ordinary clay, free from stones and grit, worked into the stiffness of soft soap in water, must be applied forming it into the shape of an egg, so that the top and bottom be made quite air-tight. A little cow or horse-manure mixed with the clay prevents it cracking during dry weather. Grafting-wax is also suitable for excluding the air, and this material can be purchased in tins from nurserymen and horticultural sundriesmen. Apples and Pears are the two fruits usually grafted, and as the latter come first into leaf, these should be given preference.

THE FLOWER GARDEN.

By A. C. BARTLETT, Gardener to Mrs. FORD, Pencarrow,
Cornwall.

Gravel walks.—The grass edges of walks should now be trimmed, and, to ensure an even edge, a garden line should be stretched along the verges, using plenty of pegs at the curves to maintain the proper sweep. Any bare or broken places should be made good by cutting a square of turf immediately behind the gap, lifting it with the turf-spade, and reversing the square so that the straight cut is in line with the verge. Reversing the turf makes a tougher

edge than drawing when the square of turf is drawn outwards. The blank space from which the sod came can be filled with spare pieces of turf that must be well beaten down. Before repairing gravel walks, examine them immediately after a heavy rain, and mark any places where the drainage is bad, so that it may be put into good order. A sprinkling of fresh gravel brightens the paths, and adds to the general good appearance of the garden. As prevention is better than cure, it will be wise, while the walks are still moist, to apply a dressing of some approved weed-killer, doing this when it seems likely that a few dry days will follow, so that the weed-killer will not at once be washed away from the roots of the weeds. Care must be taken that none falls on the grass by the side, or on any edging plants, and impress upon the person engaged in the work the poisonous nature of the compound, whether it be powder or liquid. The best treatment for a moss-covered walk is to reverse the top gravel for a depth of 2 inches with flat-tined forks, and after a few days to lightly rake and roll the new surface.

Carnations.—The border varieties which have been wintered in frames should now be planted in the permanent positions that have been previously prepared for them. Plant firmly, and tie each plant to a neat stake, so that it cannot be loosened by winds.

Sweet Peas.—Remove the lights as often as possible from the frames containing the seedlings, which were raised in heat last month, that they may be hardy enough to plant in their flowering quarters at the first suitable opportunity. When planted, the rows should immediately have sticks placed to them, and insert short branches of some evergreen on each side of the rows to further protect the plants from winds.

FRUITS UNDER GLASS.

By ALEXANDER KIRK, Gardener to J. THOMSON PATON, Esq.,
Norwood, Alloa, Clackmannanshire.

Early Vines, which have finished "stoning," will now require a steady atmospheric temperature of from 65° to 70° at night-time, and 80° to 85° during the day. Examine the bunches for the third time, and cut away with the scissors any berries where there is any appearance of overcrowding or where the berries are wedged together. Rub out all attempts at further growth, and pinch the sub-laterals at the first leaf, tying in young growths, and leaving a good expansion of foliage where there is sufficient light and space for it to develop properly. Keep the atmosphere of the house moist by damping the paths and borders twice each day. As soon as the berries commence to colour, ventilate the house more freely, and leave the top ventilator open a very little at night-time, unless the weather is unfavourable. At that stage the atmosphere should be kept much drier, decreasing the moisture by degrees. Keep a sharp look-out for red spider, which often makes its appearance just at the time the berries commence to colour. To exterminate this pest we sponge the under sides of the leaves with warm water and soft soap, which is an effectual cure if practised in time. If the pest is too far advanced for such treatment, use the syringe vigorously. Test the border with the proper tester, and if it is found to be dry, remove the mulching material to one side, and apply a good dressing of chemical vine and plant manure to the border, watering it afterwards and replacing the mulching. This watering will be sufficient until the Grapes have finished colouring, which will be from four to five weeks after the commencement, according to the variety.

Fig trees, which are now swelling their fruits, whether growing in pots or borders, will require abundance of water at the roots, otherwise the fruits will drop. Afford the pot Fig trees manure water twice each week, and mulch the inside borders with moss-litter manure. Tie in a sufficient number of young growths, and cut out those that are not required. Pinch the shoots at the fourth or fifth leaf. This pinching will result in a second crop in autumn. Do not allow the trees to carry too heavy a crop at one time. Admit air during favourable weather, and maintain a moist, warm atmosphere. Close the house early in the afternoon. Syringe the plants freely morning and night.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir Trevor Lawrence, Bart., Burford, Surrey.

Deciduous Calanthes.—Where a number of the different varieties of *C. vestita* can be grown, also such beautiful hybrids as *C. Veitchii*, *C. V. alba*, *C. Victoria regina*, *C. bella*, *C. Sedenii*, *C. Harrisii*, *C. Burfordensis*, *C. versicolor*, *C. Wm. Murray*, *C. Sibyl*, *C. Cooksonii*, *C. Phoebe*, *C. Oakwood Ruby*, and many others, a succession of flowers may be kept up for a considerable time, and with the addition of the later flowering varieties as *C. Bryan*, *C. Regnierii*, *C. Stevensii*, *C. Sanderiana*, *C. Turnerii*, *C. T. nivalis*, and *C. luteo-oculata gigantea* a continual show of bloom may be had from November till the beginning of April. Those plants which bloomed early will need attention as to potting immediately growth recommences, or before they make any roots. Do not allow the pseudo-bulbs to remain for a second year in the old soil, for, however fresh it may now appear, it will be in a condition unsuitable for the young roots during the growing season. Turn out the plants from their pots, and shake them out of the old soil. Shorten the dead roots to within 1 inch of the base of the pseudo-bulbs. By retaining this much, and pressing the potting material firmly around them, the bulbs may be kept in their place until the new roots obtain a firm hold of the compost. The old pseudo-bulbs from which last year's growth was formed may be divided, and the leading bulbs may either be grown singly in small pots, or several bulbs planted 2 or 3 inches apart in larger ones. It is essential that the drainage be free and open, and the soil in the same condition. Where this is properly attended to, there need be no fear of over-saturating them with water, of which they require large quantities, especially later on, when the new pseudo-bulbs are forming. Therefore, the pots should be filled to nearly half their depth with clean broken crocks, over which should be placed a thin layer of turfy loam or rough sphagnum-moss. The soil should consist of three parts turfy loam, the other part being made up with leaf-soil, finely chopped sphagnum-moss, broken crocks, and coarse silver sand, the whole being well mixed together. If the loam is not of a sufficiently fibrous nature, some extra peat and moss may be employed with advantage. The potting should be carried out as it is done with ordinary plants, keeping the base of the young growth just below the level of the compost, the latter being about half an inch beneath the rim of the pot. After potting the plants, place them in the lightest and best position available in the East Indian house. They may also be grown perfectly in the ordinary plant or Pine Stoves, also in Cucumber and warm propagating houses. For a few weeks after potting is completed, the plants will need no water, merely damping round the pots until the growths begin to advance, and carefully sprinkling the soil until the new roots lay hold of the sides of the pot. After that time, the amount of water at the roots should be gradually increased. During the early stages of growth our practice is to carefully protect the plants from all strong sunshine, but as the leaves develop they are gradually inured to more light, the ventilation being increased accordingly. The back pseudo-bulbs may be used to increase the stock, and if inserted thickly into pots filled with sphagnum-moss will soon commence to grow. They should then be re-potted and treated as previously advised for the other plants.

THE KITCHEN GARDEN.

By WILLIAM H. HONESS, Gardener to C. COMBE, Esq., Cobham Park, Surrey.

Asparagus beds.—The manure that was applied in the winter has probably, by this time, become settled down to a solid condition, and should, therefore, be well forked over to lighten it the roughest and longest being drawn into the alleys. This latter may be afterwards used as a covering to protect the first "heads" (growths) from frosts which often occur when *Asparagus* first makes its appearance above ground, and when it is most anxiously sought for. If a dressing of Messrs. Willis Bros.' *Asparagus* manure be applied as soon as possible, and again when cutting ceases, a great improvement in the strength of the "heads" will assuredly follow. Seed should

now be sown for making fresh plantations, and for furnishing plants for forcing purposes. If forcing is carried out to any considerable extent from home-grown crowns, the quantity of roots required is enormous, and sowings must be made in proportion every year to maintain the necessary supply. If the ground is of a heavy nature, raised beds should be prepared, consisting principally of good, light soil, but if the soil is of a light description, and it has been liberally provided with some decayed manure during the winter, nothing further will be required except a dressing of wood ashes, which should be well raked-in among the surface soil. Sow the seeds thinly in drills drawn at 18 inches apart, and when the seedlings are several inches above the surface thin them out to about 6 inches apart, keeping the plantation scrupulously clear of weeds, as few crops are liable to suffer more from neglect in this way than *Asparagus*. *Conover's Colossal* is one of the best varieties, for although the Giant French is a little larger it does not prove so prolific in these gardens.

Cauliflowers that have stood the winter in frames, and have been thoroughly hardened, may now be planted out where they are intended to mature, choosing a south border, or a nice warm position in the garden, and one where the plants may be easily got at, as protection at night time may be necessary for some little time longer. Or they can be placed between rows of early Peas, in trenches provided with a good layer of dung at the bottom, and sufficiently deep to allow the top of the plants to be a little under the top of the ridges. These ridges, with the rows of Pea sticks on either side, will afford a certain amount of protection, but in the event of frost of such severity as we experienced on March 11, viz. 12°, additional coverings of mats placed horizontally across the trenches, or other improvised means must be adopted. If they are planted in another situation than between the Peas, plant them in similar trenches drawn at 2 feet apart, putting each plant at a distance of 18 inches from its neighbour. Continue to prick off spring-sown plants as soon as these are large enough, watering them in the morning whenever this is found to be necessary. A further sowing may now be made, and another next month of *Veitch's Autumn*, *Walcheren*, or other suitable varieties.

Brussels Sprouts.—Plants raised from seeds that were sown in a gentle heat last month, and that have been gradually shifted into cooler quarters, will now be ready for pricking out into a cold frame. Employ some rich soil as an inducement to quick growth. A further sowing should be made towards the end of the month for raising plants for the main crop, thus providing them with a good long season to develop and mature.

PUBLIC PARKS AND GARDENS.

By W. W. PRITTIGREW, Superintendent of the Parks and Open Spaces in the City of Cardiff.

FISH-HATCHING—Continued from p. 170.

Males and females sorted and put into tubs.—As soon as it is found that the trout are working up stream, the decoy pond is netted out each morning. All those caught at one time are put into large tubs placed in readiness, and as soon as the pond is cleared they are all examined and selected, males being put into one tub and females into another. The small fish are put back into the stream, as only the best and largest are retained for spawning purposes. The selected females are first examined, and any which are unripe are put back into a pond for a few days longer to mature, while those which are ready to give off their eggs have them stripped from them.

Taking eggs from females and fertilising.—This, as may be imagined, is a very delicate undertaking, which has to be done rapidly and carefully, so that the fish is not in any way injured after it. The trout to be spawned is taken out of the water and held over a dry basin, into which the eggs are discharged by means of a gentle pressure of the ball of the thumb being applied in a downward direction to the fish just below the throat. As the ova passes from the fish, the thumb is gradually moved down to the place of exit until every egg has been given off. When a few thousand ova have been taken from one or more fish, a male

fish is milted over them, and the whole mass of eggs stirred up. As soon as the fish have been spawned they are put into a salt bath, from which they are returned to the stream, none the worse for their experience in the hands of their captors. A remarkable circumstance in connection with the artificial process of fertilising trout eggs is that the less water there is about them the quicker and surer does fertilisation take place. After the milt has been applied to the eggs water is poured over them, and not before.

Cleansing of ova.—The ova must not be finally laid down in the hatching trays until the surplus milt left about them and all dirt is thoroughly washed away, otherwise a fungoid growth soon makes its appearance and very quickly destroys the eggs. For about 24 hours after the ova has been taken from the fish it can be moved about in water almost with impunity, but as soon as that period has passed they cannot again be interfered with until the embryo has become what is known as "eyed."

The period of incubation all depends upon the temperature of the water passing over them. As in the case of plant seeds, it is said there is a minimum, optimum and maximum temperature governing the periods of incubation of fish ova. In one of our hatcheries where the temperature of the water this winter has been 45°, the ova was 85 days in hatching. In the open-air hatchery the water temperature is always 50°, and the ova only takes 45 days' incubation—in fact, the young trout in this hatchery are feeding before the ova in the other hatchery are hatched, even when it is laid down on the same date at both places.

Feeding of Alevins.—For about the first four weeks of their existence the young trout require no feeding, as their yolk sac contains sufficient nutriment to maintain them for that period. By the end of that time, however, the sac becomes absorbed and they begin to feed, when the difficulties of fish rearing may be said to first actually commence. Prior to this all is plain sailing, but as soon as feeding has to be taken in hand the death-rate among the young fish goes up by leaps and bounds.

Stocking of streams.—Once the young trout are able to feed the sooner they are put into the rearing ponds the better. This is also a good time to stock streams with them, when it is intended to do so with fry. Stocking with trout at this stage results in a great many dying off while still young, but as they cost so little up to that time, if only a very small percentage succeed in establishing themselves, a great advantage is gained with very little expense.

Rearing ponds.—The provision of plenty of rearing ponds is very necessary if any appreciable measure of success is to be attained in rearing young trout, and in a public park this is one of the greatest difficulties. These ponds are best made narrow and long, say, 100 feet long by 6 feet wide, running shallow at both ends, and as deep as possible in the middle. Each pond should be so constructed that no fish can possibly escape from the one to the other. They should also be connected by shallow winding streamlets, so that the water passing from one pond to another gets perfectly aerated in its passage. During the greater part of the season the ponds should be constantly covered with screens to prevent their becoming overgrown with fresh-water algae, which, when too abundant, have a very detrimental effect upon the young fish. The fish should be netted out every few weeks, and the stronger ones selected from the weaker. If this is not done the bigger fry will worry the weaker ones, and even feed upon them, with such results that the numbers will very rapidly diminish.

Nature of food.—The food we use for the young fish with the most satisfactory result is very finely-ground-up sheep's liver, mixed with boiled oatmeal. Although it is wise to give as much variety as possible in the way of food to them, we find they hardly ever tire of this mixture.

Cleanliness is the motto of every successful fish breeder—clean water, boxes, ponds, and food are all essential for success. Anyone who may be thinking of starting a trout hatchery cannot commence too soon in looking out a suitable site for it and making all the preparations necessary for carrying on such an undertaking during the next season.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

Illustrations.—The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

APPOINTMENTS FOR THE ENSUING WEEK.

WEDNESDAY, MARCH 27—
Roy. Bot. Soc. Exhib. at Regent's Park.

FRIDAY, MARCH 29—Good Friday.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—49° 8'.

ACTUAL TEMPERATURES:—

LONDON.—Wednesday, March 20 (6 P.M.): Max. 55°; Min. 46°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, March 21 (10 A.M.): Bar., 30° 4'; Temp., 48°; Weather—Bright sunshine.

PROVINCES.—Wednesday, March 20 (6 P.M.): Max. 52°, S.W. Ireland; Min. 42°, Scotland N.E.

SALES FOR THE ENSUING WEEK.

MONDAY—

Border Plants and Bulbs, Perennials, Roses, Azaleas, &c., at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.

TUESDAY—

507 cases Japanese Lilliums, also Miscellaneous Bulbs, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 1.

WEDNESDAY—

Herbaceous Plants, Lilliums, Azaleas, Palms, Plants, &c., at 12; Roses and Fruit Trees at 1.30 and 4; at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

Roses, Lilies, Azaleas, &c., at Steven's Rooms, King Street, Covent Garden, W.C., at 12.30.

**The
Veitch
Medallists
of the
Year.**

To the small but select body of those on whom the honour of a Veitch medal has been conferred may now be added, taking them in their alphabetical order, Mr. J. G. Baker and Mr. Worthington Smith. The first-named is a distinguished botanist, the second an eminent botanical artist, an engraver, a keen student of fungi, a well-known archæologist. As much of their work has been known through these pages, and they take rank with Lindley, Paxton, Berkeley, Westwood, Hooker and others who have used our columns for the benefit of horticulture, we are confident that many who are conversant with their work but who may not know them personally will acknowledge that the trustees have made a good selection, and will feel an interest in the portraits we now lay before our readers.

Mr. Baker began his botanical career by a critical study of British plants and their distribution. A wider field was opened out to him when he became attached to the Herbarium of the Royal Gardens, Kew, of which establishment he was eventually curator, and remained in that office till his retirement. Of the enormous amount of work that he did in that capacity it is not necessary for us to speak. It must suffice to say that Mr. Baker early

recognised the necessity, for horticultural purposes, of studying wherever possible the living representatives and of not confining himself to the examination and comparison of herbarium specimens. He soon found that the Monocotyledonous plants, such as the Lilies and their allies, specially demanded the critical examination of living plants, inasmuch as they were often, and of necessity, badly preserved in herbaria. And so it was that monograph after monograph was prepared of Lilies, of Irises, of Amaryllids, of Musas, many of them published in our own columns and still more in the *Journal of the Linnean*

the cultivator in search of information, a practised hand can fill in the details for himself. It must not, however, be thought that the synthetical was the only aspect of Mr. Baker's work. Those who know what he has done in unravelling the critical forms of Brambles, Roses, and Hawkweeds, will appreciate his powers of minute analysis as much as his broad grasp of generalities.

If we feel that we are too intimately associated with Mr. Baker to be altogether impartial judges of his work, what shall we say of Mr. Worthington Smith? To him this journal has been largely indebted for its illus-

WORTHINGTON G. SMITH (VEITCH MEMORIAL MEDALLIST).

Society. Taking up the study of Ferns where Sir William Hooker had left it, Mr. Baker also soon became an authority on those plants. His object in all cases was to bring into prominence the principal groups so as to facilitate the researches of his successors. We have heard him compare his work to that of a maker of a map of a large and crowded city. His first care was to lay down the principal thoroughfares, and to leave the minor details of secondary streets, &c., to be filled in as opportunity might serve.

This is the kind of work most useful to

trations of plants for over 40 years. As a botanical artist he has had no rival since the death of Walter Fitch, who was also a contributor to our columns. Beauty and firmness of outline, secured by long practice as an engraver, and accuracy of detail, rather than impressionist effect, characterise his work, and thus his drawings are far more valuable for practical purposes than those which aim at general and often fleeting effect.

Of his work among fungi we need not here dwell, the Natural History Museum contains very numerous illustrations of his skill,

Photo by E. J. Wallis.

THE LAKE, ROYAL GARDENS, KEW.

nor can we here do more than allude to his researches into the manners and customs, the weapons and tools of prehistoric man; indeed, his position as an archæologist is an assured one, and his published works on these subjects are permanent assets in the library of the student.

There is one feature of Mr. Smith's character well known to his friends, but perhaps not so generally recognised by those whose knowledge of him is less intimate. We allude to his sense of humour. This finds expression at all sorts of times and on all occasions. By way of example, we repeat an illustration showing the difficulties under which our artist sometimes had to labour when adequate facilities for the execution of his task were not forthcoming, and another showing the device adopted by the late G. F. Wilson to preserve his Peas from the too insistent attentions of the sparrows, which is referred to again in this column in a letter (now reproduced) purporting to have been written by the cat.

We refrain from saying more of our colleagues and friends, as such publicity might be unwelcome to them, and who knows how the artist would avenge himself at our expense! Let us conclude by congratulating them on the honour conferred on them and by expressing the hope that our columns may long continue to be enriched by their productions.

LETTER FROM THE LATE MR. WILSON'S CAT.

"Weybridge, 1872."

"DEAR EDITORS.—When your woodcutter was down here lately, he advised me to send you a rough scratch of my position in Mr. W——'s garden, and he requested me at the same time to briefly tabblylate for the purrusal of your readers, how I purrfect my master's plants from being potted by small birds. I can only trust your readers will believe my a-mews-ing tail!

"Here is the sketch (fig. 86) as well done as my talent will admit. You see I live in a nice clean beer-barrel purrposely selected for me, so that whenever I 'wire-in' to rest at night my felines revert to my master's favourite ale-o!

"This rough scratch explains better than any words how I 'clear a bed,' and daily practice the art of 'forcing' and 'striking.' I also teach the birds the equally useful art of 'cutting.' The cat-kin tribe are known always to be well 'up to the scratch' in a garden; so I may say as a concluding claws that I never encourage any pussylaninuous feelings towards sparing sparrows, or purrfecting small birds. May such felines always be fur from yours truly, Mr. W——'s Cat."

OUR SUPPLEMENTARY ILLUSTRATION.—The charming view of the lake in the Royal Gardens, at Kew, shown in the supplementary illustration to the present issue, affords an instance of the effect produced amongst other vegetation by fastigate or upright growing trees. The picture may appropriately be studied in connection with Mr. BEAN's article on this subject, and the accompanying illustrations on another page.

ROYAL BOTANIC SOCIETY.—The first of the special monthly exhibitions of plants and flowers in the Royal Botanic Gardens, Regent's Park, London, will take place on Wednesday next, March 27.

THE NATIONAL CARNATION AND PICOTEE SOCIETY (southern section) has issued its thirtieth

the artificial formality dear to specialists of the old school. Fortunately there is scope for both groups of Carnation lovers, and as the society endeavours to cater for all there is no reason for complaint on this score. It is, we think, to be regretted that a similar catholic spirit was not manifested in the case of the tree or winter-flower-

FIG. 85.—WORTHINGTON G. SMITH WORKING UNDER DIFFICULTIES.

report, containing a list of prize winners in last year's exhibit and the schedule of prizes to be competed for in the R.H. Hall, Vincent Square, on July 24 of the present year. The society shows signs of progress in providing for the exhibition of flowers in their natural state and in gradually abandoning the childish practice of exhibiting the flowers with cardboard collars. The increased and increasing popularity of the flower is the best evidence that the great bulk of flower lovers dislike

ing Carnations; that an "extra special" society should have to be formed to include the devotees of these very popular flowers, because the "special" society was too limited in its scope to admit them, is one of those mysteries that no outsider can comprehend. With fortnightly meetings and special committees of the R.H.S. which could be multiplied if thought requisite the use for special societies save for commercial purposes seems less than ever.

FIG. 86.—A FELISITOUS MODE OF TRAINING A MEMBER OF THE CAT-RIN TRIBE.

AMERICAN WINTER-FLOWERING CARNATIONS.—A grower of these varieties states in *Müller's Deutsche Gärtner-Zeitung*, No. 10 of the present year, that, contrary to the usual practice with ordinary winter-flowering varieties, of taking cuttings in late summer and autumn, keeping the young plants in cold houses and pits during the winter, and planting them out in the spring, the American winter-flowerers are struck from cuttings taken in the following seasons for flowering in the greatest quantity: in autumn, winter, and spring. Those plants that are struck in the interval between January and March are generally cut back twice, and those struck in April only once. American varieties develop much more rapidly than the European ones, and flowering, according to varieties, begins in September and October. The best shoots for taking as cuttings are those that appear at the base of the flower stems, and care is taken to remove only a few of these, as those that are left soon throw up flower shoots after the first flower shoots are removed. One of the evils which accrue when the American varieties are kept cool in the winter season is that the growth is unnaturally checked, the base of the stems becomes woody, which is the first stage of the dreaded decay of the stems—a disease that has brought these Carnations into some degree of disrepute. The right kind of culture is that which aims at maintaining the plants in full growth. When cuttings are taken in the autumn and much warmth afforded the plants, they become weak, and the tissues soft, and the germ of many evils laid.

SALE OF ORCHIDS AT WEST POINT.—A sale of 122 lots of duplicate plants from the collection of S. GRATRIX, Esq., West Point, Whalley Range, Manchester, was held at West Point by Mr. HAROLD G. MORRIS, of the firm of PROTHORPE & MORRIS, 67 and 68, Cheapside, London, on Thursday, March 14. The sale realised a total of £1,208. The highest price for a lot was 800 guineas, the plant being *Odontoglossum crispum* "Britannia," a small plant of *O. crispum* *Mundyanum*, with two pseudo-bulbs, realised 150 guineas, and other high prices were *O. crispum* *Luciani*, 180 guineas; *O. crispum* "Mrs. A. Warburton," 88 guineas; *O. crispum* *Lindenii*, 50 guineas; *O. crispum* "Mary Gratrix," a charming white form, 36 guineas. Among *Cypripediums* C. The Baron secured 120 guineas; four plants of C. *Minos Youngii* realised from 17 to 33 guineas each; C. *Leonia*, Gratrix's variety, 55 guineas; two plants of *Cypripedium* *Emperor of India*, 20 and 22 guineas respectively, and upwards of 20 guineas were obtained for other *Cypripediums*; the older favourites, such as good forms of C. *euryades*, appearing to have increased in value; a plant of C. *euryades* *magnificum*, New Hall Hey variety, reaching 46 guineas. White *Cattleyas* were also in favour, and of these C. *Hardyana albens* realised 70 guineas. A small plant of *Lycaste Skinneri armeniaca* fetched 21 guineas, and small plants of L. Samuel Gratrix and Mary Gratrix 10 and 10½ guineas respectively.

RETIREMENT OF MR. H. J. CLAYTON.—"An Old Pupil" writes: "I am sure I shall express the feelings of many horticulturists in stating how sorry I am to learn that Mr. CLAYTON's connection with Grimston Park Gardens, Tadcaster, Yorkshire, is about to cease. He has been head gardener there for 35 years, and his retirement will take place on April 16. Having spent several years of my life under him there I can testify that a more considerate man to his fellow helpers in keeping up the well-known reputation of the gardens could not be, but he was also strictly just to his employers. I know it will be a great wrench for him to leave his work at Grimston, having often heard him remark that he thinks he has held close communion with every bough and

twig in the beautiful, well-stocked gardens and grounds. As a practical gardener, to use his own expression, he did not care to put his garden soil into a few small flower pots, but delighted in the trees and shrubs. Mr. CLAYTON's long sustained interest in the garden charities is well known. I was living at Grimston in 1887 and well remember with what keen interest he followed the inception of the Royal Gardeners' Orphan Fund. He has been, on and off, churchwarden, &c., for nearly 30 years, having also managed a small Sunday school on one side of the parish during the whole time. Being in his 65th year it is out of the question his securing another situation, although fairly well in health. He has taken a house in the village of Ulleskelf, which is a township, like Grimston, in the parish of Kirkby Wharfe, and hopes to get some employment as a horticultural adviser, &c., &c. I am sure he will have the good wishes of all who have known him." Mr. CLAYTON is an old and valued correspondent of this journal, and on many occasions he has kindly sent us specimens from the Grimston Gardens that have proved his cultural skill. Our correspondent, "An Old Pupil," mentions that Mr. CLAYTON "followed" the inception of the Royal Gardeners' Orphan Fund, but it should be remembered that he and the late Mr. PENNY were the first to suggest simultaneously the formation of the fund.

LONDON'S TOBACCO CROP.—"In spite of frosty nights and sunless days London's tobacco crop under glass at the Royal Botanic Society's gardens in Regent's Park is getting on apace. The crop is not large; it is purely experimental. But to make it more interesting a large number of the best known varieties of the tobaccos of commerce are included. Mr. HAWES, the society's head gardener, reports that all the plants, whether from Kentucky, Virginia, Havana, or from Turkish, German or Dutch seed, are doing well, the adverse weather notwithstanding. Some of the seedlings are picked out in separate flower pots in which they will get individual treatment and the maximum of light. In another five or six weeks it is confidently asserted that the growing tobacco will show the distinctive characteristics of the various sorts included in the experiment. The public will have a chance of seeing this novel crop at the Royal Horticultural Hall in April on the occasion of the 3rd International Tobacco Trades Exhibition." Tobacco.

SPECIAL SPRING NUMBERS.—As winter gives place to spring, so the garden periodicals bud out and manifest signs of increasing energy and progress pleasant to witness. The *Scottish Gardener* is one of the youngest of the fraternity, and, as becomes its age, is fresh and vigorous. The spring number is full of good, sound, practical articles, and is adorned with numerous portraits of practitioners who, as we know, well maintain the reputation of Scotch gardeners. A note informs us that this is "the first attempt at a special number." A glance at its pages is sufficient to show that the attempt has been a highly successful one. The *Gardeners' Magazine* has slightly altered its size, improved its "get up," and in various ways proves its determination to keep abreast of the times. The *Journal of Horticulture* caters for the professional gardener, whose requirements are well looked after. It is doing good work in stimulating and encouraging the rising generation. The *Gardener* is bright and lively, and full of information for the benefit of the amateur. The amateur is indeed well provided for, as among the number of inexpensive journals intended for his benefit are included *Amateur Gardening*, an excellent pennyworth; *Gardening Illustrated*, crammed with information; *Garden Life*, well illustrated; the *Gardening World*, replete with trustworthy information; and others, all good in their way, whether they issue special spring numbers or not.

CAN PLANTS OBTAIN NITROGEN FROM THE AIR?—When it is remembered in how very large a proportion nitrogen enters into the composition of the atmosphere, it is not to be wondered at that the idea should be entertained that plants must be able to avail themselves of the supply by which they are so copiously surrounded. The researches and experiments of BOUSSINGAULT and of LAWES and GILBERT, however, are almost universally accepted as proving that the plant does not absorb free nitrogen from the atmosphere. Lately, however, Mr. THOMAS JAMIESON, the "Director of Research" of the Agricultural Research Association of Aberdeenshire, whose report for the year 1906 is before us, has strenuously advocated the opposite opinion, and asserts positively that the nitrogen of the air is "directly absorbed and fixed by plants" by means of specialised organs adapted for the absorption of nitrogen. Demonstration of these statements is, says he, afforded by "strictly controlled culture of plants of a gain in weight of nitrogen due to absorption from the atmosphere." How and by what means the nitrogen is dissociated from the oxygen is not explained. This matter is one for the chemist to determine. The physiologist will require further proof than is offered by Mr. JAMIESON, that sundry hairs which are common to a very large variety of plants have anything to do with the absorption of nitrogen. That Mr. JAMIESON should find nitrogenous compounds in those hairs is not remarkable, seeing that they must contain in their active state a considerable amount of protoplasm, whence that nitrogen came, is not to be proved by mere assertion that it entered the plant by means of these hairs, nor do we imagine that the "main work of Rothamsted" (mis-spelt throughout Mr. JAMIESON's report as Rothamstead) is likely to be "overturned by the new doctrine." There are other statements in former reports and repeated in this one, such as that an "aperture exists at the extremity of the root hairs," and that "the three feathery-like structures in the flowers of cereals and grasses are not parts of the female organ of the plant (as formerly supposed), but are brushes that serve to expel the male organs to the air for diffusion of the pollen all around."

We find it difficult to accept these statements as correct, though we are aware that an aperture has occasionally been seen at the end of a root-hair, as by GASPARINNI. We must remain, till further evidence is afforded, in the position of those teachers "who have to receive the material for instruction from the results of investigation properly established, and also that, if they fail to do so, by assuming greater knowledge than the investigators themselves, or from other improper reasons, the result is—that their students suffer." In view of the great practical importance of the subject, we could wish Mr. JAMIESON's observations and inductions could be confirmed.

BOUNTY FOR THE STUDY OF SOILS.—The Worshipful Company of Goldsmiths has made a donation of £10,000 to the Lawes Agricultural Trust (Rothamsted Experimental Station) to be devoted to research in connection with the soil, and to be known as the Goldsmiths' Company's Fund for Soil Investigation.

THE DECIMAL SYSTEM.—At the private view on March 13 of the new premises in Kingsway, Messrs. J. GRIFFIN & SONS, LTD., displayed in their vestibule a memorial in favour of the universal adoption of the decimal system, which is signed by such a diverse section of the community—including physicians, journalists, clergymen, educational authorities, barristers, solicitors and photographers—as to encourage us to think that this system will eventually be adopted in this country.

POLEMONIACEÆ.—A family to which the Phlox, the Cobæa, the Cantua, the Gilias, and various other garden flowers belong, is naturally one which has a special interest for botanist-gardeners. On this account it is of interest to note the publication in the *Pflanzenreich* of a special monograph by Mr. A. BRAND, of the Polemoniaceæ. The text is mainly in German, but the descriptions of the genera and species are in botanical Latin understood by specialists everywhere, and illustrated by woodcuts which appeal to all and sundry whatever their nationality may be. The work is mainly of botanical interest, but as we have said, owing to the large number of cultivated forms it appeals to horticulturists also. Thus six species of Cobæa are mentioned, three of which are figured. Polemonium includes 18 species, many of which are critically analysed so that various sub-species and varieties are enumerated. Forty-eight species of Phlox are described and tabulated; of *P. paniculata* three garden varieties are enumerated. As the result of crossing Phlox maculata and *P. paniculata* a whole host of garden forms are enumerated, includ-

BRAZILIAN ORCHIDS.—M. COGNIAUX, whose ability is only equalled by his industry, has published in the Bulletin of the Royal Botanical Society of Belgium some notes additional to his monumental enumeration of the Brazilian Orchids in the *Flora Brasiliensis* recently completed. During the progress of that work and since its publication much further information has been obtained, a digest of which is given in M. COGNIAUX's memoir. Many additional newly discovered Brazilian species are described, and an enumeration of the species found in neighbouring countries such as the Guianas, Paraguay, Uruguay, and the Argentine Republic is afforded. Some notes on the geographical distribution of the species is given from which it appears that the entire number of species known up to this time in Brazil is 1,795, 172 of which are described by M. COGNIAUX as new, 1,476 are Brazilian, and 819 extra Brazilian. Of the 1,476 species recorded from Brazil 1,188 are exclusively Brazilian, 288 being found also beyond the confines of that country. Pleurothallis, Epidendrum, and Onci-

wages from \$50.00 to \$60.00 per month. Should any young men care to venture to the United States and come to New York they would find that almost any seedsman would have upon his books openings for young men as above, or if they should communicate with the *Chronicle* you could put them in communication with me, and I should be pleased to furnish them with further information. Harry O. Bunyard, 342, West 14th Street, New York. [We should not care to undertake the responsibility of advising anyone to seek work in a foreign country, but we will give such information as we can. Our own colonies are in many ways preferable to the United States. —Ed.]

THE FLOWERING OF THE ALMOND.—The first flowers on an Almond tree in a favourable position in Wandsworth, south-west of London, expanded fully on Wednesday last, March 20, as against February 28 last year, March 7 in 1905, and March 21 in 1904.

HOW ENGLISH WORDS CREEP INTO USE IN FOREIGN LANGUAGES.—It is a curious thing to note the adoption of English words in languages allied to our own, and possessing their counterparts, although not so convenient or expressive. Especially is this the case with things connected with sport, with horses, horse racing and dogs. The latest that has come under our notice is Poney-Rasenmäher (mowing machine of a size suitable for being drawn by a pony). The proper German word for pony is *klepper*, or *kleine pferd*; but the advertiser, LUDWIG MÖLLER, of Erfurt, adopts the word pony to make his advertisement intelligible to his countrymen.
